In a double-blind, placebo-controlled, crossover study, 12 nurses working night shifts (3-4 consecutive nights followed by 3 days of rest) were given 1.2 g of ginseng (not further specified) or placebo for three consecutive nights of night work and tested on the morning after the third night. Crossover medication was given after an interval of at least 2 weeks. A third test series was carried out during normal daytime working, after no medication and a good night's sleep (GNS). The subjects assessed their mood, physical well-being and degree of lethargy with linear self-rating scales; two psychophysiological performance tests and haematological tests were also carried out. The detrimental effects of night shifts on mood and performance were clearly seen. A constant trend in favour of ginseng compared to placebo was noted. Ginseng ratings were favorable for mood criteria, but less favourable for physical well-being criteria. Ginseng restored blood glucose levels raised by night shift stress to the GNS level [Hallstrom 1982].

Various tests of psychomotor performance were carried out in a group of 16 healthy male volunteers given a standardized ginseng extract (2 × 100 mg daily for 12 weeks) and in a similar group given placebo in a double-blind, randomized study. A favourable effect of ginseng relative to baseline performance was observed in attention (cancellation test), processing (mental arithmetic, logical deduction), integrated sensory-motor function (choice reaction time) and auditory reaction time. End performance of the ginseng group was superior (p<0.05) to placebo only in mental arithmetic. No differences were found in tests of pure motor function, recognition and visual reaction time [D'Angelo 1986].

The effects of 400 mg/day of a standardized extract for 8-9 weeks on a variety of cognitive functions were compared with placebo in a randomized, double-blind study involving 112 healthy volunteers aged more than 40 years. The extract group (n=55) showed a tendency to faster simple reactions and significantly (p=0.02) better abstract thinking than controls (n=57). No significant difference between groups in concentration, memory or subjective experience was observed [Sørensen 1996].

In a double-blind, placebo-controlled, crossover trial, 27 healthy young adults completed a 10 minute "cognitive demand" test battery at baseline followed by intake of either an extract (4% ginsenosides) or placebo and 30 minutes later consumed a drink containing glucose or placebo. A further 30 minutes later they completed the "cognitive demand" battery six times in immediate succession. Depending on their allocation on the particular day, participants received either 0 mg extract/0 mg glucose (placebo); 200 mg extract/0 mg glucose (ginseng); 0 mg extract/25 g glucose (glucose) or 200 mg extract/25 g glucose (ginseng/glucose combination). The test battery comprised a Serial Threes subtraction task (2 min); a Serial Sevens subtraction task (2 min); a Rapid Visual Information Processing task (5 min); and a "mental fatigue" visual analogue scale. Blood glucose levels were measured prior to the day's treatment, and before and after the post-dose completions of the battery. Both the extract and glucose enhanced performance of the mental arithmetic task and ameliorated the increase in subjective feelings of mental fatigue experienced by participants during the later stages of the sustained, cognitively demanding task performance. There was no evidence of a synergistic relationship between the extract and exogenous glucose ingestion on any cognitive outcome measure. The extract caused a reduction in blood glucose levels 1 hour following consumption when ingested without glucose [Reay 2006].

A randomized, double-blind, placebo-controlled, crossover trial was performed in 30 volunteers (mean age 22.87 years) receiving 200 mg extract (4% saponins), 400 mg of extract and placebo for 8 days, in a counter balanced order, with a 6-day wash-out period. Subjective mood and working memory were assessed on days 1 and 8 of each treatment period, at pre-dose, 1, 2.5 and 4 h post-dose. Dose-dependent treatment effects (p<0.05) were observed. The 200 mg dose slowed the decrease in mood at 2.5 and 4 h on day 1 and at 1 and 4 h on day 8, and slowed responding on a mental arithmetic task across day 1 and at 1 and 2.5 h on day 8. The 400 mg dose improved calmness (restricted to 2.5 and 4 h on day 1) and improved mental arithmetic across days 1 and 8 [Reay 2010].

In a randomized, double-blind, placebo-controlled study, 52 healthy volunteers were randomly allocated to receive either enzyme-modified ginseng (2 g/day) or placebo for 4 weeks. Fatigue scores using the Visual Analogue Fatigue Scale (VAFS) and Revised Piper Fatigue Scale (RPFS) were considered as the primary outcome measure. Quality of life scores were investigated using the Short-Form Health Survey (SF-36). The VAFS score decreased more in the treatment group than in the placebo group (p=0.033). There was no difference in the RPFS and SF-36 scores between the two groups [Lee N 2016].

In a single-blind, randomized study involving 65 healthy students (mean age 23±4 years), 35 received ginseng (500 mg/day, not further specified) and 30 placebo. Data were obtained at baseline and after one month. Psychological stress was induced with a psychomotor performance task and visual working memory accuracy testing and assessed using the Perceived Stress Scale (PSS) and by serum malondialdehyde (MDA) levels. There were significant ($p<0.0001$) improvements in reaction times in the psychomotor performance task and in visual working memory accuracy in the ginseng group after treatment compared to baseline; there was no significant difference in the placebo group. The control group showed a significant ($p=0.0004$) increase in serum MDA associated with a significant ($p<0.0001$) increase in the PSS score. In contrast, in the ginseng group a much smaller but still significant ($p=0.02$) increase in the PSS score was associated with a significant ($p<0.0001$) reduction in serum MDA [Al-Kuraishy 2017].

Subjects (mean age 40.4±1.5 years) working in stressful occupations and with high scores on the stress response inventory (≥81) and Beck Depression Inventory (≥10 ≤30), were randomized to receive either red ginseng (2 g/day; n=32) or placebo (n=31) for 6 weeks in a double-blind study. In assessing parameters associated by the authors with adaptogenic activity, all participants underwent a comprehensive psychological evaluation using the Perceived Stress Scale, the Profile of Mood States questionnaire and the Sheehan Disability Scale, cognitive evaluation involving the continuous performance test (CPT), as well as biological evaluation including blood levels of lipids, glucose, catecholamines and inflammatory markers and heart rate variability. After 6 weeks of treatment with ginseng, there were no significant effects on psychological or cognitive function, although there was a non-signficant improvement in the correct response time in the CPT. In the ginseng group however, triglyceride levels were significantly ($p=0.048$) increased but still within the normal range and the level of epinephrine was significantly ($p=0.043$) decreased, with a significant ($p=0.041$) negative correlation between these two effects, this being consistent with one hypothesis for mediating stress [Baek 2019].

Immunumodulatory activity

The effects of ginseng on various immune parameters were studied in a randomized, double-blind study in healthy volunteers of both sexes (18 to 50 years), treated orally with either 2 × 100 mg of a standardized extract (n=20) or 2 × 100 mg of a dry aqueous extract (n=20) or placebo (n=20) daily for 8 weeks. The standardized extract increased the chemotaxis of circulating polymorphonuclear leucocytes ($p<0.05$ at week 4 and $p<0.001$ at week 8), the phagocytosis index and phagocytosis fraction ($p<0.001$ at weeks 4 and 8), total lymphocytes (T3) ($p<0.05$ at week 4 and $p<0.001$ at week 8), the T-helper subset (T4) ($p<0.05$ at week 4 and $p<0.001$ at week 8), the helper/suppressor (T4/T8) ratio ($p<0.05$ at weeks 4 and 8) and enhanced induction of blastogenesis in circulating lymphocytes ($p<0.05$ at weeks 4 and 8 after induction by cocanavalin A and pokeweed mitogen; $p<0.001$ at weeks 4 and 8 after induction by lipopolysaccharide) and natural killer cell activity ($p<0.05$ at week 4 and $p<0.001$ at week 8). The dry aqueous extract increased the chemotaxis of circulating polymorphonuclear leucocytes ($p<0.05$ at weeks 4 and 8), the phagocytosis index and phagocytosis fraction ($p<0.05$ at week 8), T3 ($p<0.05$ at week 4 and $p<0.001$ at week 8), T4 ($p<0.05$ at week 8) and enhanced induction of blastogenesis in circulating lymphocytes ($p<0.05$ at week 8 after induction by cocanavalin A and pokeweed mitogen) and natural killer cell activity ($p<0.05$ at week 8). With placebo, only enhancement of natural killer cell activity was significant ($p<0.05$) after 8 weeks [Soldati 1988; Scaglione 1990].

Healthy volunteers were treated with 100 mg of a standardized ginseng extract (n=114) or placebo (n=113) daily for 12 weeks in a multicentre, randomized, double-blind, placebo-controlled study investigating potential effects of ginseng on resistance to influenza and common cold. All participants received an anti-influenza polyvalent vaccine at week 4. There was a highly significant difference ($p<0.001$) between the extract and placebo groups with regard to the frequency of influenza or colds observed between weeks 4 and 12 (15 cases in the verum group versus 42 cases in the placebo group). Antibody titres at week 8 were also significantly ($p<0.0001$) higher after verum treatment (272 units versus 171 units after placebo) and natural killer cell activity was almost twice as high in the verum group as in the placebo group at weeks 8 and 12 ($p<0.0001$) [Scaglione 1996].

A study in two groups of 10 healthy young males evaluated the effects of 300 mg of a standardized extract daily for 8 weeks in comparison with placebo on peripheral blood leukocytes and lymphocyte subsets. No significant differences were observed [Srisurapanon 1997].

Antioxidant activity

In a randomized, double-blind, placebo-controlled trial, 82 postmenopausal women (aged 45-60 years) received either 3 g/day of red ginseng or placebo for 12 weeks. Antioxidant enzyme activity (superoxide dismutase, glutathione peroxidase) and oxidative stress markers (malondialdehyde, 8-hydroxydeoxyguanosine) were assessed, and the homeostatic model assessment of insulin resistance index was calculated, at baseline and at the end of the trial. A total of 71 women completed the study. Serum superoxide dismutase activity was significantly increased with ginseng compared to baseline ($p<0.001$) and placebo ($p=0.004$). Serum malondialdehyde levels showed a signficant decrease compared to baseline ($p=0.001$), but a non-significant decrease compared with placebo ($p=0.064$). No significant changes were noted in serum glutathione peroxidase and 8-hydroxydeoxyguanosine levels. Ginseng showed no significant effects on fasting glucose, fasting insulin, insulin resistance, inflammatory markers and liver enzymes [Seo 2014].

Clinical Studies

Effects on fatigue and quality of life

In a randomized, double-blind, placebo-controlled trial, 53 cancer patients (15 men, 38 women) received either ginseng (not further specified; 3 g/day; n=32) or placebo (n=21) for 12 weeks. Results from the quality of life questionnaires showed significant improvements in the ginseng group compared to placebo for the General Health Questionnaire-12 total score ($p<0.01$) and the 'psychological domain' scores of the WHO Quality of Life Assessment-Bref (WHOQOL-BREF; $p=0.02$). There was a tendency towards improvement in the WHOQOL-BREF 'physical health' ($p=0.06$) and 'environment' ($p=0.07$) domain scores in the ginseng group when compared with placebo [Kim 2006].

In a randomized, double-blind, placebo-controlled trial, 90 patients (21 men and 69 women; aged 20 to 60 years) with idiopathic chronic fatigue received either an extract (20% ethanol; 1 or 2 g per day) or placebo for 4 weeks. Fatigue severity, was assessed at 0, 2 and 4 weeks using a self-rating numeric scale (NRS) and a visual analogue scale (VAS), with change in fatigue severity considered a primary endpoint. Glutathione reductase (GSH-Rd) activity and serum levels of ROS, MDA and GSH were determined at 0 and 4 weeks. All groups demonstrated a time-dependent decrease in the total NRS score; although the decrease was greater in the extract groups compared to placebo, the difference was not significant. In the

sub-analysis, physical symptoms did not significantly improve but the mental fatigue symptoms did significantly ($p<0.01$) improve in the extract groups compared to placebo. Only the higher dose significantly ($p<0.05$) reduced the VAS score compared to placebo. ROS and MDA levels were significantly ($p<0.05$ to $p<0.01$) lowered in both extract groups compared to placebo. The lower dose significantly ($p<0.05$) increased total serum GSH concentration and GSH-Rd activity compared to placebo [Kim 2013].

In a randomized, double-blind, placebo-controlled study, 60 female multiple sclerosis patients received either 250 mg ginseng (not further specified) or placebo twice daily for 3 months. Outcome was measured by the Modified Fatigue Impact Scale (MFIS) and the Iranian version of the Multiple Sclerosis Quality Of Life Questionnaire (MSQOL-54), and 52 patients (86%) completed the study. Ginseng demonstrated significantly greater improvements compared to placebo with regards to MFIS ($p=0.046$) and MSQOL ($p\leq0.0001$) scores [Etemadifar 2013].

In a randomized, double-blind, placebo-controlled clinical trial, 180 participants (aged 18 to 60 years) with a Traditional Chinese Medicine (TCM) diagnosis of 'deficiency syndrome' were allocated to receive capsules containing either placebo or red ginseng (3.5-4.8 g/100g of total saponins) at 1.8 or 3.6 g per day for 4 weeks; 174 patients completed the study. The primary outcomes related to safety evaluation, assessed using a 'fire-heat symptom scale' to measure changes in "fireness", as well as other safety parameters including adverse event reports, various laboratory tests and electrocardiogram. The secondary outcomes related to efficacy, assessed using a TCM fatigue symptom scale and a self-assessment fatigue scale. After 4 weeks of treatment the placebo and ginseng groups showed a significant ($p<0.05$) decrease in 'fireness' compared to their baseline values, but there were no significant differences found between the groups. Ginseng time- and dose-dependently improved fatigue compared to placebo in the self-assessment scale, with the higher dose demonstrating a signficantly greater effect from week 1 and the lower dose from week 2 ($p<0.05$ to 0.001). Ginseng also significantly ($p<0.05$ to $p<0.01$) improved the total TCM symptom score compared to placebo in a time- and dose-dependent manner. The total effective rate (number of patients exhibiting ≥ 30% total symptom score improvement) was much higher in the low and high dose ginseng groups compared to placebo, at 75%, 84.5% and 30.4% of cases respectively [Zhang 2019].

Effects on cognitive and psychological function
A Cochrane review included 9 randomized, double-blind, placebo-controlled trials. Results of the analysis suggested improvement of some aspects of cognitive function, behavior and quality of life. The evaluation showed a lack of evidence with regard to a cognitive enhancing effect of ginseng in healthy participants and no high-quality evidence about its efficacy in patients with dementia [Geng 2010].

In a double-blind, placebo-controlled study involving 50 ambulant patients suffering from asthenia, depressive syndrome or neurovegetative disorders, the effects of 8 weeks of daily treatment with 200 mg of a standardized extract on performance were evaluated by two psychometric tests and a comprehensive psychological questionnaire (Sandoz Clinical Assessment Geriatric). Significant improvement ($p<0.05$ and $p<0.01$) was seen in most of the parameters [Rosenfeld 1989].

In a 12-week randomized study, 61 patients (24 males and 37 females; aged 50-80 years) with Alzheimer's disease were assigned to receive red ginseng powder capsules at a low-dose (4.5 g/day, n=15) or a high-dose (9 g/day, n=15) or no treatment (control; n=31). The patients at the high dose showed significant improvement on the Alzheimer's Disease Assessment Scale ($p=0.032$) and Clinical Dementia Rating ($p=0.006$) after 12 weeks as compared to control [Heo 2008].

An open study assessed the effects on cognitive function of a standardised ginsenoside complex (high temperature treated ginseng). Alzheimer's patients (n=40; aged 50-90 years) were randomized to one of four treatment groups: 1.5 g/day (n=10), 3 g/day (n=10), 4.5 g/day (n=10) and control (n=10; untreated) for 24 weeks. Patients given 4.5 g/day showed significant ($p<0.05$) improvement on the Mini-Mental State Examination and The Alzheimer's Disease Assessment at 12 and 24 weeks compared to baseline [Heo 2012].

In randomized, double-blind, placebo-controlled clinical trial, 90 subjects with mild cognitive impairment received either 3 g of ginseng powder or placebo for 6 months. The verum group showed significant improvement in visual learning ($p=0.041$) and visual recall ($p=0.040$) after 6 months when compared to placebo [Park 2013].

In an open, 8-week prospective study, 35 female outpatients (aged 18-65 years), in remission from major depression but with some residual symptoms, were given an extract (21.08 mg/g ginsenosides) at an initial dose of 2 g/day and increasing to 3 g/day by week four and continuing at 3 g/day for the following 4 weeks. Symptoms were evaluated using the Depression Residual Symptom Scale, Montgomery-Åsberg Depression Rating Scale (MADRS), the Clinical Global Impressions Scale for Severity (CGI-S) and the Depression and Somatic Symptom Scale (DSSS). Residual symptoms improved from baseline to week four, still being apparent at week eight ($p<0.01$). The mean MADRS score decreased from 6.7 ± 2.7 at baseline to 5.1 ± 3.1 at week four and to 4.4 ± 3.1 at week eight ($p<0.001$). The general severity of symptoms was significantly ($p<0.001$) attenuated on the CGI-S from baseline (16.7 ± 11.1) to week four (13.1 ± 9.6) and week eight (14.1 ± 9.6; $p<0.001$). DSSS scores as reported by patients also significantly ($p<0.01$) improved from 16.7 ± 11.1 at baseline to 13.1 ± 9.6 at week four and 14.1 ± 9.6 at week eight [Jeong 2014].

Effects on respiratory disease
In a controlled single-blind study with a standardized extract (200 mg/day) in 40 patients suffering from chronic bronchitis, the extract significantly ($p<0.001$) improved alveolar macrophage activity compared to baseline [Scaglione 1994].

In a pilot study involving 15 patients with severe chronic respiratory diseases, a standardized extract was administered orally at 200 mg/day for 3 months and respiratory parameters such as vital capacity, expiratory volume and flow, ventilation volume and walking distance were evaluated. The extract improved pulmonary function and oxygenation capacity, which seemed to be the reason for improved walking capacity [Gross 1995].

In a nonblinded, randomised, comparative pilot trial the effects of an extract (4% ginsenosides) on the bacterial count [number of colony forming units (CFU)] in the bronchial systems of 75 patients with acute bacterial attacks of chronic bronchitis were investigated. All patients received 875 mg amoxicillin and 125 mg clavulanic acid twice daily for 9 days. They were then further randomised into two groups, one (n = 37) receiving only the antibacterial treatment, the second (n = 38) also receiving 100 mg of the extract. Beneficial effect of the extract on the reduction of bacterial counts were seen in the bronchial systems of patients. Significant group and time effects were found after analysis of the evolution of bacterial counts. Statistically

significant differences between treatment groups were observed on days 4, 5, 6 and 7 (p = 0.0049, p = 0.0104, p = 0.0175, p = 0.0182, respectively), while a borderline trend (p = 0.0554) was seen on day 8 [Scaglione 2001].

Effect on dry eye syndrome
In a randomized, double-blind, placebo-controlled study involving 49 glaucoma patients treated with antiglaucoma eye drops, the effects of ginseng on dry eye syndrome were evaluated. Patients received either 3 g of extract (16.46 mg/g ginsenosides; n=24) or placebo (n=25) daily for 8 weeks. The extract significantly (p<0.01) improved the tear film stability and total Ocular Surface Disease Index score as compared to placebo [Bae 2015].

Antidiabetic effects
In a systematic review and meta-analysis of randomized controlled trials in diabetic patients and healthy individuals, 16 trials were included. Ginseng significantly reduced fasting blood glucose compared to control (MD = 20.31 mmol/L [95% CI: 20.59 to 20.03], p=0.03) with no significant effect on fasting plasma insulin, glycated haemoglobin or homeostasis model assessment of insulin resistance. Subgroup analyses did show significant reductions in glycated haemoglobin (MD = 0.22% [95%CI: 0.06 to 0.37], p=0.01) in parallel compared to crossover trials [Shishtar 2014a].

In a randomized, double-blind, placebo-controlled, crossover study, 20 patients with type 2 diabetes (mean age 51.5±1.9; mean HbA1c 7.4 ±0.4%) took ginseng (not further specified; 2 x 369 mg capsules three times daily; n=10) or placebo (n=10) for 4 weeks. After treatment with ginseng, a significant (p<0.05) decrease in insulin resistance by 45% was shown when compared to a 12% decrease with placebo [Ma 2008].

In a randomized, double-blind, placebo-controlled study, 15 overweight or obese subjects (aged 46±3 years) with impaired glucose tolerance or newly diagnosed type 2 diabetes were given either an extract (not further specified; 3-8 g/day; n=5), ginsenoside Re (250-500 mg/day; n=5) or placebo (n=5) for 30 days. Neither the extract nor ginsenoside Re improved beta-cell function or insulin sensitivity [Reeds 2011].

In a double-blind, randomized, placebo-controlled study, 72 diabetic patients (older than 18 years) received 1.5, 2 or 3 g/day of a vinegar ginseng extract (yielding high levels of ginsenoside Rg3) or placebo for 8 weeks. The extract significantly (p<0.05) reduced the HbA1c level compared to baseline: by 0.56 ± 0.25% in the 1.5 g group, by 0.31 ± 0.12% in the 2 g group and by 0.29 ± 0.11% in the 3 g group; with the 1.5 g group also exhibiting a significant (p=0.021) decrease compared to placebo. Patients' fasting plasma glucose concentration decreased by 21.40, 14.27 and 6.76 mg/dL for the 1.5, 2 and 3 g doses respectively, and by 2.25 mg/dL for placebo; the lowest extract dose alone demonstrated a significant decrease compared to both baseline and placebo (p<0.05). The percentage of patients whose HbA1c decreased by >0.5% was significantly (p<0.01) greater than placebo in the 1.5 and 2 g groups. Interestingly, improved glucose homeostasis in this study was associated with decreased concentrations of pro-inflammatory cytokines, TNF-α and IL-6, both implicated in the pathogenesis of diabetes. [Yoon 2012].

In a randomized, double-blind, placebo-controlled trial involving 42 patients (aged 20-75 years) with either type 2 diabetes or fasting glucose impairment, one group was given placebo and the other fermented red ginseng (2.7 g/day) for four weeks. A significant reduction in postprandial glucose levels (p=0.008) and increase in postprandial insulin levels (p=0.04) compared to placebo were observed. Fasting blood glucose in the ginseng group was significantly (p=0.04) lower at week 4 compared to baseline but not compared to placebo. Fasting plasma insulin and lipid profiles were not significantly different from placebo [Oh 2014].

In a randomized, double-blind, placebo-controlled trial, 41 individuals (aged 20-70 years) received either 5 g/day of red ginseng (n=21) or placebo (n=20) for 12 weeks. Subjects were either newly diagnosed with type 2 diabetes or had a fasting blood glucose level between 100 to 125 mg/dL. A 2-h glucose tolerance test was taken at baseline and after 12 weeks of treatment. At 30 minutes, significant decreases in serum glucose (-22.24 ± 10.77 mg/dL; p=0.016) and whole blood glucose levels (-17.52 ± 5.22 mg/dL; p=0.002) were found when compared to baseline. There were no significant changes in blood glucose-related indices in the placebo group [Bang 2014].

The antidiabetic effects of a fermented ginseng extract were evaluated in an 8-week, randomized, double-blind, placebo-controlled study. Participants with impaired fasting glucose levels, without any diagnosed disease, received either the extract at 960 mg/day (total saponins 16.18 mg/g; n=12) or placebo (n=11). Impaired fasting glucose and postprandial glucose levels significantly (p<0.05) decreased in the verum group compared to placebo [Park SH 2014].

Effects on erectile dysfunction
A meta-analysis of 7 randomized, clinical trials involving 349 individuals showed a significant effect on erectile dysfunction (p<0.00001). Subgroup analyses (n=135) demonstrated beneficial effects of red ginseng in psychogenic erectile dysfunction [Jang 2008].

In a double-blind, placebo-controlled, crossover study, 45 patients (mean age 54 years) were treated with 900 mg ginseng (not further specified) or placebo three times a day for 8 weeks, with a 2-week washout period between treatments. The mean International Index of Erectile Function (IIEF) scores were significantly (p<0.01) higher after treatment with ginseng when compared to placebo [Hong 2002].

In a randomized, double-blind, placebo-controlled study, 60 patients with mild to moderate erectile dysfunction received either 1 g of red ginseng (not further specified; n=30) or placebo (n=30) 3 times daily. The International Index of Erectile Function (IIEF-5) score was significantly improved after verum as compared to baseline (from 16.4 ± 2.9 to 21.0 ± 6.3, p<0.0001). In contrast, no difference was observed in the placebo group (from 17.0 ± 3.1 to 17.7 ± 5.6, p>0.05). The Global Assessment question found that 20 patients in the ginseng group reported significantly improved erection (p<0.01); with no improvement reported in the placebo group. Scores on questions 2 (rigidity), 3 (penetration), 4 and 5 (maintenance) were significantly (p<0.01) higher for verum compared to placebo after 12 weeks. For the verum, there was a significant improvement in total score (IIEF-5 score) in questions 3 and 5 (p<0.001 and p<0.0001 respectively). The levels of serum testosterone, prolactin and cholesterol were not significantly different between verum and placebo after treatment (p>0.05) [De Andrade 2007].

In an 8-week randomised, placebo-controlled trial, 69 patients with mild to moderate erectile dysfunction received either placebo (n=34) or an extract (not further specified; n=35). Erectile function was significantly (p<0.05) improved in the verum group compared with placebo after 8 weeks of treatment. Sexual desire was significantly (p<0.001) increased in the ginseng group compared to baseline [Ham 2009].

Table 1: Clinical studies with ginseng preparations

First Author Year	Study Design	Type of patient No. of patients (test/control)	Preparation type Daily dose Duration of treatment	Studied parameters	Outcome
METABOLIC CONDITIONS					
Hosseini 2017	R / D-B / P-C	Men and women with type 2 diabetes 48 (24/24)	Standardized ginseng extract 3 x 100 mg 42 days	Effect on chemerin, apelin and glycaemic biomarkers	Improved fasting glucose ($p<0.01$) and fasting insulin ($p<0.05$), no effect on chemerin or apelin.
Hosseini 2016	R / D-B / P-C	12 Men and 28 women with type 2 diabetes 40 (20/20)	Standardized ginseng extract 100 mg 56 days	Blood sugar control and inflammatory markers	Reduced fasting blood glucose, IL-6 ($p<0.05$) and high sensitive C-reactive protein (hsCRP) ($p<0.01$).
Bang 2014	R / D-B / P-C	28 Men and 13 women with type 2 diabetes 41 (21/20)	Korean red ginseng 5 g 84 days	Antidiabetic effect	Significant decrease in serum insulin and C-peptide concentrations ($p<0.01$) at 30 minutes.
Park SH 2014	R / D-B / P-C	Patients with impaired fasting glucose 23 (12/11)	Hydrolyzed ginseng extract 2 x 480 mg 56 days	Antidiabetic effect	Decreased fasting plasma glucose ($p<0.05$) and postprandial glucose ($p<0.05$) at 60 minutes.
Shishtar 2014b	R / D-B / P-C/ crossover	12 Men and 13 women with well-controlled type 2 diabetes 25 (23/2)	Korean white ginseng (dried, powdered whole root) Single dosing on 5 separate occasions, in random order, with 1 g, 3 g or 6 g of ginseng or 3 g wheat bran (administered twice).	Effect on vascular and glycaemic parameters	Beneficial effect on augmentation index (at 3 g; indicator of arterial stiffness) ($p=0.04$). No effect on postprandial, glycaemic or other vascular parameters.
Delui 2013	R / D-B / P-C	Hyperlipidaemic patients 40 (20/20)	Ginseng extract (7 mg of ginsenosides and 2-3% ginsenosides Rb1, Rb2, Rb3, Rc, Rd, Re, Rg1) 500 mg 56 days	Hyperlipidaemia	No significant effects on lipid profile, hsCRP level and pro-oxidant/anti-oxidant balance.
Lee KJ 2013	R / D-B / P-C	Postmenopausal healthy females 93 (49/44)	Fermented red ginseng 2.1 g 14 days	Diabetes-ameliorating effects	Significantly increased levels of dehydroepiandrosterone sulfate ($p<0.05$), growth hormone and estradiol ($p<0.1$). Decreased levels of glycosylated haemoglobin ($p<0.05$), insulin ($p<0.05$), and homeostatic model assessment of insulin resistance ($p<0.1$).
Oh 2014	R / D-B / P-C	Women and men with impaired fasting glucose or type 2 diabetes 42 (21/21)	Fermented red ginseng extract 2.7 g 28 days	Postprandial glucose-lowering effect	Significant reduction in postprandial glucose levels ($p<0.01$) and increase in postprandial insulin level ($p<0.05$). No effect on fasting glucose, insulin, and lipid profiles.

Hosseini 2014	R / D-B / P-C	28 Women and 12 men with type 2 diabetes 40 (20/20)	Standardized ginseng extract 300 mg 56 days	Biomarkers of Systemic Low-Grade inflammation	Reductions in inflammatory makers IL-6 ($p<0.05$) and hsCRP ($p<0.01$).
Cho 2013	R / D-B / P-C	Healthy overweight/ obese participants 68 (34/34)	Korean red ginseng 6 g 84 days	Effect on insulin sensitivity	No improvement in insulin sensitivity.
Kwon 2012	R / D-B / P-C	Obese women 50 (24/26)	Korean red ginseng 3 x 6 g 56 days	Obesity	Reduction in body mass index. Improved quality of life.
Yoon 2012	R / D-B / P-C	Men with type 2 diabetes 72 (64/18)	Vinegar extract 1.5, 2, 3 g 56 dayS	Diabetes type-2	Moderate improvement of HbA1c level ($p<0,05$).
FATIGUE					
Yennurajalingam 2017	R / D-B / P-C	Cancer patients with an average intensity of ≥ 4/10 on the ESAS (scale, 0-10) 112 (56/56)	Standardized ginseng extract 400 mg 28 days	Cancer-related fatigue	Improvement in cancer-related fatigue, not superior to placebo.
Jiang 2017	R / D-B / P-C	18 Women and 42 men with advanced non-small cell lung cancer 60 (34/26)	Fermented red ginseng extract 3 g 60 days	Fatigue in patients with advanced non-small cell lung cancer	Significant improvement of Fatigue Symptom Inventory score ($p<0.01$), Chinese medicine symptoms score ($p<0.01$), psychological status ($p<0.01$), physical conditions ($p<0.01$), quality of life ($p<0.01$); reduced chemotherapy toxicity ($p<0.01$).
CARDIOVASCULAR CONDITIONS					
Barari 2017	R / controlled	Healthy, unathletic women (32)	Ginseng extract 5 mg/kg 42 days	Effect on serum vascular endothelial growth factor and platelet-derived growth factor	Influence on the levels of angiogenic factors (only on platelet-derived growth factor).
Zaheri 2016	R / P-C	Healthy male athletes 24 (12/12)	Standardized ginseng extract 200 mg 30 days	Heart rate, systolic and diastolic blood pressure	Improved blood circulation during exercise, decreased peripheral vascular resistance, increased oxygen delivery to actively contracting muscles.
Cha 2016	R / D-B / P-C	Non-obese, non-diabetic, prehypertensive patients (female 12, male 50) 62 (31/31)	Korean red ginseng 5 g 84 days	Blood pressure lowering effect	Reduced systolic and diastolic blood pressure ($p<0.01$), increased dihydrobiopterin levels ($p<0.05$) and decreased palmitic amide ($p<0.05$) and lysophosphatidylcholines ($p<0.01$).
Rhee 2014	R / D-B / P-C	47 Women and 43 men with systolic blood pressure (120-159) and diastolic (80-99) 90 (60/30)	Ginsenoside protopanaxatriol 100, 300 mg 56 days	Blood pressure lowering effect	Significantly reduced systolic and diastolic blood pressure ($p<0.05$) at 4th and 8th week.
Jovanovski 2014	R / D-B / P-C/ crossover	Healthy women (7) and men (9) 16 (12/4)	Korean red ginseng 3 g 12 days	Endothelial dysfunction	Significantly improved flow-mediated vasodilatation ($p<0.05$). Brachial blood pressure remained unchanged ($p=0.45$).

First Author Year	Study Design	Type of patient No. of patients (test/control)	Preparation type Daily dose Duration of treatment	Studied parameters	Outcome
Kang 2013	R / D-B / P-C	Healthy women (23) and men (17) 40 (20/20)	Korean red ginseng 1.5 g 56 days	Blood flow	Improved blood circulation.
Chen IJ 2012	Prospective study (observation phase and active treatment phase)	25 Women and 15 men with intradialytic hypotension 38 (18 patients BP ≥140/90 mmHg /20 patients BP <140/90 mmHg)	Korean red ginseng 3.5 g per session 56 days	Intradialytic hypotension	Significant reduction in degree of blood pressure drop during hemodialysis ($p<0.05$). More activation of vasoconstrictors (endothelin-1 and angiotensin II) during hemodialysis was found. The postdialytic levels of endothelin-1 and angiotensin II increased significantly ($p<0.01$).
Park 2012	R / D-B / P-C	21 Women and 39 men with metabolic syndrome 60 (29/31)	Korean red ginseng 4.5 g 84 days	Cardiovascular risks in metabolic syndrome	No effect on blood pressure, lipid profile, oxidized LDL, fasting blood glucose or arterial stiffness.
CNS DISORDERS					
Teik 2016	R/ D-B / P-C / crossover	28 women, 20 men 48 (32/16)	Panax ginseng extract 500, 1000 mg 3 days	Cognitive performance	No effect.
Jeong 2015	R / P-C	Healthy women (39) and men (12) 51 (26/25)	Korean red ginseng 56 days	White matter microstructure and cognitive functions	Significantly reduced intrusion errors ($p=0.005$), increased fractional anisotropy ($p=0.04$), improved response inhibition and white matter microstructure integrity in the prefrontal cortex.
Lee KJ 2014	R / D-B/ P-C	Postmenopausal women without hypertension or diabetes 93 (49/44)	Fermented red ginseng (FRG) 2.1 g 14 days	Depression	The effect of FRG consumption on cognitive depression (CD) occurred via the energy factor, which is mainly attributable to cholesterol. The structural regression path of the energy factor on CD showed a significant ($p<0.05$) difference between the FRG group and the placebo group.
Ko 2014	R / D-B / P-C	26 girls and 44 boys (6-15 years old) with ADHD 70 (33/37)	Korean red ginseng extract 1 g 56 days	Hyperactivity/ impulsivity	Significantly decreased inattention/ hyperactivity scores ($p<0.05$), significantly decreased quantitative electroencephalography theta/beta ratio ($p=0.001$).
Lee MH 2014	R /crossover	Healthy men 25 (13/12)	Red ginseng 32.1 mg 14 days	Effect on alcohol consumption and hangover symptoms	Relief of symptoms of alcohol hangover.

Park 2013	R / D-B / P-C	Participants with mild cognitive impairment 90 (45/45)	Korean ginseng 3 g 180 days	Cognitive impairment	Significant improvement in visual learning ($p<0.05$) and visual recall ($p<0.05$).
Han 2013	Not randomized Overnight polysomno-graphic study	Healthy men 15	Red ginseng extract 3 x 1.5 g 7 days	Sleeping behaviours	Total wake time was significantly reduced ($p=0.05$), sleep efficacy was significantly increased ($p=0.05$). Improved quality of sleep.
Heo 2012	R / P-C	30 Women and 10 men with Alzheimer's disease (30/10)	Heat-processed ginseng-SG-135 (standardized extract) 1.5, 3, 4.5 g 168 days	Alzheimer's disease	Significant improvement with 4.5 g SG treatment on the Alzheimer's Disease Assessment Scale ($p<0.05$) and Mini-Mental State Examination score ($p<0.05$).
Yeo 2012	R / D-B / P-C	Healthy men 15 (8/ 7)	Korean red ginseng 4.5 g 14 days	Cognitive and motor function	Improved cognitive function.
Chen EYH 2012	R/ D-B / P-C	51 Women and 13 men with schizophrenia 64 (32/32)	Ginsenosides (Rb1 and Rg1) 100 mg 28 days	Schizophrenia	Improved working memory.
SEXUAL FUNCTION AND INFERTILITY					
Park 2016	R / D-B / P-C	Infertile men with varicocele 80 (40/40)	Korean red ginseng 1.5 g 84 days	Infertility	Significant improvement in sperm concentration ($p<0.05$), motility ($p<0.01$), morphology ($p<0.01$) and viability ($p<0.05$).
Momoi 2015	R / D-B / P-C	Healthy men with partial impotence 45 (30/15)	Korean ginseng 200, 600 mg 12 days	Sexual function	Increased International Index of Erectile Function score ($p<0.05$).
Chung 2015	R / D-B / P-C/ crossover	Premenopausal women 23 (12/11)	Korean red ginseng 3 x 1 g 56 days	Sexual function	Improved sexual desire, arousal, orgasm and satisfaction domains.
Kim SY 2012	R / D-B / P-C	Postmenopausal women 72 (36/36)	Red ginseng + ginsenosides 3 g + 60 mg 84 days	Menopausal symptoms	Decreased menopausal symptoms. Significant improvements in Kupperman index ($p=0.032$) and in menopause rating scale($p=0.035$). Significantly decreased total cholesterol ($p=0.009$) and low-density lipoprotein cholesterol ($p=0.015$).
RESPIRATORY DISEASE					
Lee CS 2012	R / D-B / P-C	Healthy women (62) and men (38) 100 (50/50)	Korean red ginseng extract 3 x 1 g 84 days	Acute respiratory illness	Protection from contracting acute respiratory illness and may have the tendency to decrease the duration and scores of acute respiratory illness symptoms.
Wu 2014	R / D-B / P-C	9 Women and 1 man with Chronic Obstructive Pulmonary Disease (COPD) stage II-IV 10 (5/5)	Standardized ginseng extract 2-200 mg 70 days	COPD	No outcome because there were no exacerbations.

First Author Year	Study Design	Type of patient No. of patients (test/control)	Preparation type Daily dose Duration of treatment	Studied parameters	Outcome
IMPROVEMENT OF QUALITY OF LIFE IN CANCER PATIENTS					
Kim HS 2017	R / D-B / P-C	Patients with epithelial ovarian cancer 30 (15/15)	Red ginseng 3 g 90 days	Quality of life	Improved emotional functioning (p=0.027) and decreased symptoms of fatigue (p=0.012), nausea, vomiting (p=0.004) and dyspnea (p=0.021), reduced anxiety (p=0.015) and interference affecting life (p=0.035) and improved daytime somnolence (p=0.043).
Zhang 2018	R / D-B/ P-C multi-centre	Patients with stage 3, 4 non-small cell lung cancer 414 (199/215)	Ginsenoside Rg3 366 days	Median survival time	Adding ginseng to chemotherapy improved patients' symptoms and reduced chemotherapy-induced myelosuppression (p<0.05).
Kang 2018	R/ D-B / P-C	Patients underwent surgery for adenocarcinoma of the colon and received FOLFOX (20 women, 22 men) 42 (21/21)	Korean red ginseng 3 g 21 days	Protective effect in oxaliplatin-mediated splenomegaly in colon cancer	Beneficial effects against oxaliplatin-induced splenomegaly. The rate of splenomegaly was significantly lower (p=0.03).
Ma 2014	R / P-C	33 Women and 63 men with non-small cell lung cancer 96 (48 /48)	Ginseng polysaccharides with dendritic cells 0.5 mg/kg 30 days	Effect on the balance of Th1/ Th2 T helper cells	Increased expression of Th1 cytokines (IN-γ, IL-2) (p<0.01) and ratio of Th1/ Th2 (INF-γ/IL-4, IL-2/IL-5) (p<0.05), decreased FACT-L scores and expression of Th2 cytokines (IL-4, IL-5) (p<0.05).
OTHER EFFECTS					
Cho 2018	R / D-B / P-C/ crossover	Women with rheumatoid arthritis 70 (32/38)	Korean red ginseng 2 g 56 days	Rheumatoid arthritis	No significant effect.
Flanagan 2018	D-B / P-C	Healthy women (10) and men (9)	Hydrolyzed Korean Ginseng extract 960, 160 mg 14 days	Hypo-pituitary-adrenal and oxidative activity induced by intense work stress	Significantly reduced muscle damage (p<0.05) and hypo-pituitary-adrenal responses to physical stress (p<0.05).
Rocha 2018	R/ D-B / prospective	21 Women and 3 men with irritable bowel syndrome 24 (12 extract/12 trimebutine 600 mg/d)	Dry extract 300 mg 60 days	Improvement in abdominal pain	Decrease in abdominal pain.
Choi 2016	R / S-B / controlled	11 Women and 27 men with chronic Hepatitis B 38 (19/19)	Korean red ginseng + antiviral 3 g Single dose	Chronic Hepatitis B	Significant differences in hyaluronic acid (p=0.032) and transforming growth factor-β (p=0.008).
Jung 2016	R / D-B / P-C	Men with metabolic syndrome 62 (32/30)	Red ginseng 3 g 28 days	Effect on peripheral blood mitochondrial DNA copy number and hormones	Favorable effect on mitochondrial function and hormones. Increase in total testosterone level. Significantly decreased diastolic blood pressure (p<0.05) and serum cortisol (p<0.05).

Kim 2015	R / open-label	35 Women and 24 men with chronic tinnitus 59 (19: 1.5 g/day/ 20: 3 g/day/ 20 placebo)	Korean red ginseng 1.5, 3 g 28 days	Symptoms and Quality of Life in chronic tinnitus	Significant improvement of emotional and mental health scores ($p<0.05$) at 3 g/day.
Bae 2015	R / D-B / P-C	29 Women and 25 men with with glaucoma 54 (27/27)	Korean red ginseng 3 g 56 days	Effect on dry eye syndrome	Significant improvement of tear film stability and total Ocular Surface Disease Index score ($p<0.01$).
Doosti 2014	R / P-C / D-B	Men exposed to continuous noise 48 (16 NAC/16 ginseng /16 placebo)	Korean red ginseng 200 mg/day or N-acetyl-cysteine (NAC) 1200 mg/day 14 days	Noise induced hearing loss	Reduced noise-induced temporary threshold shift.
Park KS 2014	R / D-B / P-C	Women with cold hypersensitivity in the hands and feet 80 (40/40)	Korean red ginseng 2 x 3 g 56 days	Cold hypersensitivity (hands and feet)	Significantly higher skin temperature of hands ($p=0.027$) and feet ($p=0.004$), lower visual analogue scale scores ($p<0.05$), higher recovered temperature of the right 5th finger and less parasympathetic activity.
Park SY 2014	R / P-C	44 Women and 27 men with idiopathic sudden sensorineural hearing loss 73 (37 steroid group/ 36 steroid+KRG group)	Korean red ginseng with steroid 3 g 60 days	Sudden sensorineural hearing loss	No effect.
Cho 2014	R / D-B / P-C	Healthy women (70) and men (2)	Korean ginseng extract 6 g 98 days	Natural killer cell activity	Enhanced natural killer cell cytotoxic activity.
Lee JK 2013	R / D-B / P-C / multi-centre	18 Women and 10 men with biliary colic 28 (14/14)	Korean red ginseng 3 x 2.5 g 168 days	Adjuvant to the standard regimen of bile acids for gallstones	No significant reduction in stone burden ($p=0.09$).
Braz 2013	R / D-B / P-C	Women with fibromyalgia 38 (13 amytriptiline/ 13 placebo/ 12 ginseng)	Ginseng extract (27% ginsenosides) 100 mg 84 days	Fibromyalgia	Reduced number of tender points and improved quality of life.
Kim YH 2012	R / P-C	Pregnant women due to have a caesarean section 41 (21/20)	Red ginseng 4.5 g 24 days	Effect on lipid peroxide levels, protein carbonyl levels and antioxidative ability	Decreased protein carbonyl formation and prevented the reduction of antioxidative ability in maternal blood during the postpartum period after caesarean section.
Kim JY 2012	R / D-B / P-C	Healthy women (34) and men (23) 57 (19 low dose / 19 high dose/ 19 placebo)	Korean red ginseng 3, 6 g 56 days	Lymphocyte DNA damage, antioxidant enzyme activity, LDL oxidation	Decreased lymphocyte DNA damage and LDL oxidation by upregulating antioxidant enzyme activity.

R = Randomized; D-B = Double-blind; S-B = Single-blind; P-C = Placebo-controlled

In a randomised, double-blind, placebo-controlled trial, 45 healthy men with partial impotence (aged 35-70 years) received 200 or 600 mg of ginseng (not further specified) or placebo, daily for 12 weeks. Ginseng did not significantly improve male sexual function when compared to placebo, but did significantly ($p<0.05$) increase the IIEF scores when compared to baseline in both the 200 and 600 mg groups [Momoi 2015].

Pharmacokinetic properties

Pharmacokinetics in animals
The pharmacokinetics of ginsenoside Rg1 were studied in rats, comparing oral and intravenous administration. Rapid absorption of 1.9-20.0% of orally administered Rg1 (t_{max} 30 minutes) and rapid excretion of intravenous Rg1 (almost 60% of the dose in bile within 4 hours and 24% in urine within 12 hours) were detected by TLC [Odani 1983a]. Orally administered ginsenoside Rb1 was very poorly absorbed (approx. 0.1%) from rat intestine. Excretion of Rb1 after intravenous administration was biphasic with a half-life of 11.6 minutes for the α-phase and 14.6 hours for the β-phase. Excretion was mainly in the urine (44% within 120 hours) and minimal in bile (0.8% within 24 hours) [Odani 1983b].

The pattern of decomposition products of ginsenosides Rb1 and Rg1 in rat stomach was similar to hydrolysis products under mild acidic conditions except for one compound. Decomposition products in the large intestine were due to the activitiy of enteric bacteria and an enteric enzyme [Odani 1983c].

A study in mini pigs following intravenous administration of Rb1 and Rg1 confirmed findings in rats and rabbits. Rb1 was excreted biexponentially (two-compartment open model) with a half-life of 16 hours in the β-phase (20 minutes in the α-phase). Rg1 pharmacokinetics are best explained by a one-compartment model, the elimination half-life being 27 minutes [Jenny 1985].

A study in mice involving intravenous or oral administration of tritiated [^{3}H] ginsenoside Rg1 indicated rapid absorption after oral administration (approx. 30% after 1 hour). Relatively high concentrations were found in blood, liver, bile, subcutis, conjunctiva and epithelia of oral and nasal cavities and oesophagus, whereas the concentration in muscle and endocrine organs was low. Addition of total ginseng extract or of a purified ginsenoside fraction to oral administration of tritiated Rg1 did not change the distribution pattern of Rg1. Excretion of intact Rg1 in faeces and urine was low, whereas excretion of metabolites was high [Strömbom 1985].

After oral administration of ginsenoside Rb2 to rats, six decomposition products were found in the large intestine. Five decomposition products resulted from stepwise cleavage of sugar moieties [Karikura 1990].

The decomposition of ginsenoside Rb2 in rat stomach was compared to its decomposition in 0.1N HCl. There was little decomposition in the stomach with only small amounts of 24- and 25-hydroxy- and -hydroperoxy-derivatives. Decomposition in 0.1 N HCl solution yielded two main derivatives due to cleavage of a sugar moiety [Karikura 1991a].

A further study investigated the decomposition of ginsenosides Rb1 and Rb2 in rat stomach and large intestine, in 0.1 N HCl and in crude hesperidinase solution. The results confirmed a quantitatively small decomposition to hydroxy- and hydroperoxy-derivatives in rat stomach, whereas decomposition in 0.1 N HCl yielded derivatives arising from cleavage of sugar moieties. The decomposition of Rb1 and Rb2 by cleavage of sugar moieties in rat large intestine was partly due to bacteria and partly due to enteric enzymes such as β-glucosidase. Different decomposition products were found in rat large intestine compared to those found after treatment with hesperidinase [Karikura 1991b].

After oral administration of total saponins at a dose of 400 mg/kg, the protopanaxadiol type saponins exhibited relatively long t_{max} values, while the protopanaxatriol type saponins had varying tmax values, $t_{1/2}$ of 20(S)-epimers were longer than those of 20(R)-epimers [Ma 2015].

A ginsenoside-Rg2 solution was applied to rat tail vein at a dose of 25 mg/kg of 20 (R,S)-ginsenoside-Rg2, corresponding to 2 mg/kg of 20 (R)-ginsenoside-Rg2 and 23 mg/kg of 20 (S)-ginsenoside-Rg2. Blood samples were collected from the arteria carotis communis immediately before and at 1, 3, 5, 10, 20, 30, 45 and 60 min after the administration. AUC was 197.7 ± 5.2 and 1092.5 ± 84.0 for 20 (R)-ginsenoside-Rg2 and 20 (S)-ginsenoside-Rg2 respectively [Gui 2007].

Permeability of compound K (an intestinal metabolite of panaxadiol ginsenosides) through Caco-2 cell layers was intermediate as compared to metoprolol (28 x 106 cm/s) and atenolol (0.25 x 106 cm/s). After i.v. administration of 1, 2 and 10 mg/kg to rats, no significant dose dependency was found in Cl (17.3-31.3 mL/min/kg), Vss (1677-2744 mL/kg), dose-normalized AUC (41.8-57.8 μg.min/mL based on 1 mg/kg) and $t_{1/2}$. Urinary excretion was minimal for both i.v. and oral doses. The amount of compound K recovered from the entire gastrointestinal tract at 24 h was 24.4%-26.2% for i.v. doses and 54.3%-81.7% for oral doses. Following oral administration (doses of 5-20 mg/kg), dose-normalized AUC (based on 5 mg/kg) was increased at the 20 mg/kg dose (85.3 μg.min/mL) compared with those at lower doses (4.50-10.5 μg.min/mL). Subsequently, the absolute oral bioavailability was increased from 1.8%-4.3% at the lower doses to 35.0% at the 20 mg/kg dose [Paek 2006].

Pharmacokinetics in humans
Dose-dependent urinary excretion of 20(S)-protopanaxatriol glycosides (1.5% of the dose) was observed in 4 healthy volunteers after oral ingestion of ginseng powder and ginseng extract preparations corresponding to 6.2-27.6 mg of ginsenosides per day [Cui 1997].

Using selective ion-monitoring GC-MS, ginsenoside aglycones were quantified in urine from athletes who claimed to have consumed ginseng preparations for at least 10 days before urine collection. Aglycone concentrations of 2-35 ng/ml were found in 60 out of 65 urine samples [Cui 1996].

Cleavage of sugar moieties from ginsenosides Rb1, Rb2, Rc and Rd by intestinal bacteria isolated from human faecal samples has been demonstrated. *Prevotella oris* was identified as the major bacterial species with this ability [Hasegawa 1997].

The bioavailability of the protopanaxadiol group (ginsenosides Ra3, Rb1, Rd, Rg3 and Rh2) and of the protopanaxatriol group (ginsenosides Rg1, Re, Rh1 and R1) was found to be less than 5% after oral administration. Approximately 0.2%-1.2% of ginsenosides were excreted in human urine [Qi 2011]

A standardized extract (4% ginsenosides; 700 mg daily) was taken orally as a single dose on an empty stomach by two healthy volunteers. Blood and urine samples were taken 30 min before drug administration. Overall, 25 blood samples were obtained from each subject. Urine samples were collected in four fractions: 0 to 3, 3 to 6, 6 to 12 and 12 to 24 h after administration. The same two hydrolysis products of the protopanaxatriol ginsenosides, G-Rh1 and G-F1, were

identified in plasma and urine in both volunteers. In addition, compound K, the main intestinal bacterial metabolite of the protopanaxadiol ginsenosides, was detected in plasma and urine. [Tawab 2003].

There was no effect on CYP3A4, CYP1A2, CYP2E1, and CYP2D6 in healthy volunteers [Gurley 2002]. In another study, ginseng had no effect on a number of CYP isoforms, including CYP3A4, CYP1A2, CYP2E1 and CYP2D6 [Gurley 2005, Liu 2006]. However, CYP2D was slightly inhibited in elderly humans [Liu 2006].

Compound K (C-K) was absorbed into the blood 24h after oral administration of ginseng to 32 male participants, with average values for t_{max}, C_{max} and AUC of 10.76+/-2.07 h, 27.89+/-24.46 (ng/mL) and 221.98+/-221.42 (µg x h/mL) respectively. There was a correlation between the C-K transforming activity of G-Rb1 and the C-K transforming activity of ginseng extract by intestinal microflora [Lee J 2009].

The pharmacokinetics of ginsenoside Rd were assessed in healthy Chinese volunteers. In the single-dose study, a randomized, open-label, 3-way crossover design was used. Participants were assigned to 10, 45 or 75 mg Rd by intravenous infusion, with a 2-week washout period between the administrations. Plasma levels of Rd were proportional to dose, with the mean C_{max} and AUC(0-infinity) ranging from 2.8 to 19.3 mg/L and 27.9 to 212.5 mg x h/L over the dose range studied. Rd was slowly cleared from plasma ($t_{1/2}$ = 17.7-19.3 h). In a multiple-dose study, 10 mg Rd was administered once daily for 6 days. Slight drug accumulation was noted. The mean steady-state C_{max}, AUC(0-infinity) and AUC(ss) were 4.0 mg/L, 51.7 mg x h/L, and 26.4 mg x h/L, respectively. The $t_{1/2}$ was 20.5 hours, which was similar to the single-dose value [Zeng 2010].

Preclinical safety data
A 1984 review [Soldati 1984] summarized the results of several toxicity studies of a standardized ginseng root extract in animals:

Single dose toxicity
- The oral LD_{50} was determined as > 5 g/kg b.w. in the rat, > 2 g/kg in the guinea pig and > 1 g/kg in mice.
- The intraperitoneal LD_{50} was > 1 g/kg in rats and mice.
- No noticeable changes were observed in cardiovascular parameters including ECG, pulse, blood pressure, cardiac output and stroke volume in mini-pigs adminstered oral doses of the extract at 0.25, 0.5 or 2.0 g/kg b.w.

Repeated dose toxicity
- No haematological or histological abnormalities were observed in rats after oral administration of the extract at 4.0 g/kg/day for 20 days.
- No treatment-related haematological or histopathological findings were observed in beagle dogs after oral administration of the extract at 1.5, 5.0 and 15 mg/kg/day for 90 days.
- An additional study showed no changes in haematological parameters in rats following subcutaneous injection of an extract (corresponding to 100 mg of root) daily for 5 days [Lewis 1983].

Reproductive toxicity
- No decrease in growth rate or reproduction and no treatment-related haematological or histopathological findings were observed in rats during a 33-week two-generation study with an extract administered orally at 1.5, 5.0 or 15 mg/kg b.w./day.

Embryo, foetal and perinatal toxicity
- No abnormalities of foetal development were found after oral administration of an extract to rats at 40 mg/kg/day during days 1-15 after mating or to rabbits at 20 mg/kg/day during days 7-15 after mating.

Genotoxicity
- In the hepatocyte-DNA repair test no genotoxicity was observed for an extract at concentrations of 0.1-10 mg/mL, with or without ginsenosides, or for ginsenoside Rg1 at 1-50 µg/ml.

In a study involving intraperitoneal administration of ginsenosides Rb1 and Rg1 to mice at 25, 50 or 100 mg/kg b.w., neither single nor repeated large doses of 100 mg/kg caused any toxic symptoms or adverse behavioural effects such as ataxia or sedation [Kim 1998].

Further toxicity studies were summarized in Chan 2007:

Table 2: LD_{50} (mg/kg) values for ginseng [NLM 1998a,1998b]

Samples	Animals	Route	LD_{50} (mg/kg)
Panax ginseng	Rat	oral	750
	Mouse	oral	200
	Mouse	i.p.	54

Genotoxicity
An extract was not mutagenic in two independent bacterial mutagenicity assays, each conducted with or without exogenous metabolic activation enzymes (S9 mix from Aroclor 1254-induced male Sprague-Dawley rat or Syrian hamster liver) in the Ames-Test. Bacterial strains tested included *Salmonella typhimurium* strains TA 97, TA98, TA100, TA102, TA104, and TA1535, as well as *E. coli* strain WP2 uvrA/pKM101. Furthermore, no significant increases were seen in the frequencies of micronucleated erythrocytes in the peripheral blood of male or female B6C3F1 mice exposed to 1 to 5 g/kg ginseng via gavage for 3 months [National Toxicology Program 2011]

Carcinogenicity
There was no evidence of any carcinogenic activity of an extract in male or female F344/N rats or B6C3F1 mice administered at 1.25, 2.5 or 5 g/kg for two years. The incidence of mammary gland fibroadenoma was significantly decreased in the 5 g/kg group of female rats [Chan 2011].

The safety profile of extract G115 was evaluated in a recent review. It was summarized as having no adverse effects on reproductive parameters or treatment-related effects on animal behaviour, physical appearance or food consumption [Bilia 2020].

Clinical safety data
A Cochrane review including 9 randomized, double-blind, placebo-controlled trials found no serious adverse events associated with ginseng [Geng 2010].

In a double-blind, placebo-controlled study involving 60 females and 60 males, daily oral administration of 200 mg of a standardized extract for 12 weeks did not cause any significant differences in blood levels of sex hormones (luteinizing

hormone, follicle-stimulating hormone, testosterone, oestradiol) in comparison with placebo groups [Forgo 1981b].

In an open study of 49 menopausal women, regular speculum examinations and cytological smears from the cervix and vaginal wall did not reveal any changes during 3 months of oral treatment with 200 mg of a standardized ginseng extract per day [Reinhold 1990].

In a randomized, double-blind, placebo-controlled study involving 60 physically active men (aged 17- 22 years), oral administration of 3 g/day of powdered root for 8 weeks did not lead to any abnormal changes in markers of liver or renal function [Kulaputana 2007].

No severe adverse events were observed in a randomized, double-blind study involving 72 type 2 diabetic patients given 1500 to 3000 mg of a vinegar extract of ginseng or placebo for 8 weeks [Yoon 2012].

There were no serious adverse events reported in a randomised, double-blind, placebo-controlled trial involving 90 subjects with mild cognitive impairment given 3 g/day of ginseng powder or placebo for 6 months (Park 2013).

There were no serious adverse events reported in a randomized, double-blind, placebo-controlled study involving 28 patients given 7.5 g/day steamed ginseng root or placebo for 24 weeks, in addition to a standard bile acid regimen for dissolution of gallstones (Lee JK 2013).

In a double-blind, placebo-controlled study, 60 female multiple sclerosis patients received 250 mg ginseng (not further specified) twice daily for 3 months. No serious adverse events were observed during follow-up [Etemadifar 2013].

There were no serious adverse events reported in a randomized, double-blind, placebo-controlled trial involving 80 female participants with cold hypersensitivity in the hands and feet adminstered either 3 g/day of ginseng powder or placebo for 8 weeks (Park KS 2014).

In a randomized, double-blind, placebo-controlled clinical trial involving 180 participants, there were no signficant adverse effects demonstrated in any of the safety parameters measured [Zhang 2019].

Case reports of possible allergic response

- A 20 year old male patient experienced a respiratory allergy, with skin and blood pressure effects, after ingestion of an Asian ginseng syrup [Wiwanitkit 2004].
- A 29 year old female patient exposed to airborne Korean ginseng dust showed a positive bronchial provocation and positive responses to a skin-prick test [Lee JY 2006].
- A 34 year old woman developed recurrent dyspnoea, wheezing, and nasal symptoms associated with Korean ginseng at work. Allergen bronchial provocation testing to Korean ginseng extract showed a typical immediate response, and skin prick testing resulted in a strong positive response [Kim 2008].
- A 44-year-old man developed anaphylaxis after oral intake of fresh ginseng with rhinorrhea and nasal stiffness, followed by respiratory difficulty with wheeze and abdominal pain 10 minutes after ingestion [Lee JY 2012].

Case reports with causal relationship not established

For the following case reports, a causal relationship between the intake of ginseng and the described reaction could not be established:

- Two cases of vaginal bleeding were reported in a study on sexual dysfunction in menopausal females [Oh 2010].
- One case of hypoglycaemia was reported in a study on glucose metabolism in healthy subjects [Oh 2014].

Table 3: Clinical safety studies

First Author Year	Study Design	Type of patient No. of patients (test/control)	Preparation type Daily dose Duration of treatment	Studied parameters	Outcome
Seong 2018	R / open label	Healthy participants (male 15) (15/0)	Red ginseng extract 0.8 g, 1.5 g 15 days	Drug Interaction	Poses minimal risks for clinically relevant CYP- or OATP-mediated drug interactions, well tolerated.
Song SW 2018	R / D-B / P-C / multi-centre	Healthy participants (female 724, male 268) 992 (490/502)	Korean red ginseng 2 g 168 days	Safety and tolerability	No significant abnormal changes in anthropometric, laboratory, and vital sign measurements.
Cho 2014	R / D-B / P-C	Healthy participants (female 70, male 2) 72 (36/36)	Korean ginseng extract 6 g 98 days	Efficacy and safety	No severe adverse events or alterations in complete blood cell count or blood chemistry.
Lee NH 2012	R / D-B / P-C	Healthy participants (female 129, male 41) 170 (113/57)	Ginseng extract 1 g or 2 g 28 days	Safety and tolerability	Safe, tolerable, no toxic effect with mild adverse events, such as dyspepsia, hot flash, insomnia, and constipation.

R = Randomized; D-B = Double-blind; S-B = Single-blind; P-C = Placebo-controlled

- After consuming daily ginseng drinks for 3 months, a 26-year-old man with chronic myelogenous leukaemia taking imatinib at 400 mg/day was diagnosed with hepatotoxicity [Bilgi 2010].

- After taking a ginseng preparation for cold for 1 month, an 83 year old woman with chronic kidney disease presented to an emergency department with symptoms of dizziness and general weakness for 1 day accompanied with unexplained bradyarrhythmia [Liao 2010].

- A 12 year old boy was diagnosed with gynaecomastia after 1 month of consuming red ginseng extract daily to enhance his performance [Kakisaka 2012].

- A 64 year old man complained of the temporary loss of vision for less than one hour on 2 occasions spaced 2 days apart after using a preparation containing 500 mg Korean Ginseng daily over a period of 13 days for asthenia [Martínez-Mir 2004].

- A 56 year old woman with previous affective disorder presented in a manic episode while taking an extract. Symptoms disappeared rapidly with low doses of neuroleptics and benzodiazepines [Vazquez 2002].

- A 26 year old healthy individual with no history of psychiatric illness reported manic symptoms after taking Chinese ginseng [Engelberg 2001].

- A 39 year old female patient experienced menometrorrhagia following oral and topical use of ginseng [Kabalak 2004].

- A 48 year old woman had uterine bleeding after using a combination product containing ginseng [Palop-Larrea 2000].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

GRAMINIS RHIZOMA 2016

Couch Grass Rhizome

DEFINITION

Couch grass rhizome consists of the whole or cut, washed and dried rhizome of *Agropyron repens* (L.) Beauv. (*Elymus repens* (L.) Gould, *Triticum repens* L.); the adventitious roots are removed.

The material complies with the monograph of the European Pharmacopoeia [Graminis rhizoma].

CONSTITUENTS

The characteristic constituents are polysaccharides, principally the branched fructosan triticin (3.5 -12%) [Arni 1951, Berger 1960] together with about 10% of unidentified mucilaginous polysaccharides [Bradley 2006, Gorecki 2007]; flavonoids, especially quercetin and luteolin glycosides [Stanic 2000, Weston 1987]; phenolic glucosides (ca. 1.7%), mainly the 5-glucosides of 5-hydroxyindole-3-acetic acid and 5-hydroxytryptophan [Hagin 1989, Hagin 1991, Whitehead 1983]; phenolic acids [Whitehead 1983], and a small amount (ca. 0.02%) of essential oil containing carvacrol (10.8%), *trans*-anethole (6.8%), carvone (5.5%), thymol (4.3%), menthol (3.5%) and other terpenes [Boesel 1989].

Other constituents include phenylpropanoid esters [Koetter 1993, Koetter 1994], fatty acids [Boesel 1989], phytosterols [Boesel 1991, Koetter 1993] and sugar alcohols (mannitol and inositol) [Steinegger & Hänsel 1992].

CLINICAL PARTICULARS

Therapeutic indications
Irritable bladder and other urinary tract disorders [Hautmann 2000, Brayfield 2014]. Efficacy in these indications is plausible on the basis of human experience and long-standing use [Robert 1986, Schilcher 1989, Pieroni 2002, Pieroni 2005].

Posology and method of administration

Dosage

Adults and children over 12 years
5-10g of the drug daily as an infusion [Wichtl 2009, Blumenthal 1998, BHP 1983]; fluid extract (1:1, 20-25% ethanol V/V): 2-4 ml three times daily [BHP 1983, Hautmann 2000]; tincture (1:5, 40% ethanol V/V): 5-15 ml three times daily [BHP 1983].

Method of administration
For oral administration.

Duration of use
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.

Special warnings and special precautions for use
None required

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available.
In accordance with general medical practice, the product should not be used during pregnancy without medical advice.

Effects on ability to drive and use machines
None known.

E/S/C/O/P MONOGRAPHS

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antiadhesive activity
A hydroethanolic (50%V/V) lyophilized extract of couch grass rhizome decreased adhesion of uropathogenic *Escherichia coli b*acteria to a cell line derived from human urinary bladder carcinoma by interacting with bacterial outer membrane proteins with an IC_{25} of 630 µg/mL ($p<0.05$) [Rafsanjani 2013].

In vivo experiments

Diuretic activity
Oral administration of an aqueous extract from couch grass rhizome (prepared as a 1% maceration) to rats at 50 ml/kg b.w. increased diuresis with a diuretic index of 1.42 compared to control animals receiving a corresponding amount of water only. Intraperitoneal administration to rats of an equivalent dose, in the form of an aqueous solution of a dry hydroalcoholic extract corresponding to 10% of dried rhizome at 5 ml/kg, increased diuresis with a diuretic index of 1.62 [Racz-Kotilla 1971].

In rats given an infusion of couch grass rhizome (3 g/litre) for 7 days instead of tap water, in combination with a standard diet, diuresis increased significantly compared to controls ($p<0.005$), as did the calcium content of the urine ($p<0.005$), while the magnesium content of the urine decreased ($p<0.005$). In a similar experiment, except with the rats on a high protein diet, no significant differences were observed in diuresis (the control value was much higher than for rats on the standard diet) or urinary calcium, but the decrease in urinary magnesium and an increase in urinary phosphate were highly significant (both $p<0.0005$), while the urinary pH decreased to 5.9 compared to 6.5 in controls ($p<0.01$) [Grases 1995].

Sedative effect
A 10% infusion of couch grass rhizome was administered orally to mice in doses equivalent to 40 and 80 mg of crude drug, and intraperitoneally in doses equivalent to 10, 15, 20, 40 and 80 mg of crude drug, per 20 g mouse. Sedative effects were measured by several methods including motility testing. Compared to the motility of control animals receiving only water (orally) or physiological saline (intraperitoneally), motility decreased to 95.9 and 36.1% respectively in groups receiving the infusion orally, and to 73.9, 51.4, 22.8, 18.9 and 2.4% respectively in groups receiving it intraperitoneally [Kiesewetter 1958].

Anti-inflammatory activity
A hydroethanolic (80% V/V) dry extract of couch grass rhizome, administered orally at 100 mg/kg b.w., inhibited carrageenan-induced rat paw oedema only weakly, by 14% compared to 45% by indometacin at 5 mg/kg. The oedema was produced by injecting 0.1 ml of a 1% carrageenan suspension into the plantar surface of the rat hind-paw [Mascolo 1987].

Effects on lipid metabolism
The effects of a lyophilized aqueous extract from couch grass rhizome on plasma cholesterol and triglyceride levels and also b.w. were evaluated in normal and streptozotocin-induced diabetic rats after a single oral dose of 20 mg/kg, and during repeated oral administration at the same dose level once a day for 2 weeks. Distilled water was used as a control and oral sodium vanadate (a known triglyceride- and cholesterol-lowering agent) at 0.8 mg/kg b.w. as a reference drug.

In normal rats
- a single dose of the extract or sodium vanadate did not cause significant changes in cholesterol or triglyceride concentrations.
- repeated administration of the extract produced a significant decrease in cholesterol after 7 days ($p<0.05$) and in triglycerides after 4 days and 7 days ($p<0.05$), although these effects were no longer evident on day 15. Sodium vanadate treatment led to significant reductions in cholesterol ($p<0.001$) and triglycerides ($p<0.01$) by day 15.
- repeated administration of the extract caused a slight increase in b.w. at day 15 ($p<0.01$), whereas with sodium vanadate b.w. significantly and continuously decreased over the treatment period ($p<0.001$ at day 15).

In streptozotocin-induced diabetic rats
- a single dose of the extract produced a significant decrease in both cholesterol ($p<0.001$) and triglyceride ($p<0.01$) concentrations at 6 hours after treatment; sodium vanadate had similar effects (cholesterol, $p<0.01$; triglycerides, $p<0.01$).
- repeated administration of the extract caused a significant decrease in both cholesterol and triglyceride concentrations at days 4 ($p<0.05$), 7 and 15 ($p<0.001$). Sodium vanadate produced comparable effects ($p<0.001$ for both cholesterol and triglycerides at day 15).
- both treatments led to a significant decrease in b.w. by day 15 ($p<0.01$ for the extract; $p<0.001$ for sodium vanadate).

The authors concluded that repeated oral administration of the couch grass rhizome aqueous extract had a lipid lowering effect and reduced b.w. in severely hyperglycaemic rats [Maghrani 2004].

Hypoglycaemic activity
In a further study by the same research group, the effects of a lyophilized couch grass rhizome aqueous extract on plasma glucose levels in normal and streptozotocin-induced diabetic rats were evaluated using the same dosage regimen, i.e. a single oral dose of the extract at 20 mg/kg or repeated oral administration at that dose level once a day for 2 weeks. Again, distilled water was used as a control and oral sodium vanadate at 0.8 mg/kg b.w. as a reference drug.

In normal rats
- a single dose of the extract caused a significant decrease in plasma glucose levels I hour ($p<0.001$) and 4 hours ($p<0.001$) after administration, with less significance after 6 hours ($p<0.05$). Sodium vanadate treatment produced a more modest decrease in plasma glucose after 2 hours ($p<0.01$) and 4 hours ($p<0.05$).
- after repeated daily administration of the extract, a significant reduction in plasma glucose was observed on day 2 ($p<0.01$), day 4 ($p<0.001$) and day 7 ($p<0.001$), returning to normal by day 15. No significant changes in plasma glucose were observed in rats treated with sodium vanadate.

In streptozotocin-induced diabetic rats
- a single oral dose of the extract caused a significant decrease in plasma glucose 4 and 6 hours after administration ($p<0.001$).
- after repeated daily administration of the extract a significant decrease in plasma glucose was observed from day 2 to day 15 ($p<0.001$); sodium vanadate had a similar effect.
- in contrast, plasma glucose levels in control rats (treated with distilled water only) gradually increased to a maximum on day 4.

Basal plasma insulin levels were not affected by the extract or sodium vanadate. It was concluded that the couch grass rhizome aqueous extract had a potent hypoglycaemic effect in streptozotocin-induced diabetic rats [Eddouks 2005].

Clinical studies
In a surveillance study (open, uncontrolled, multicentre) 313 patients, two-thirds of them female, with diagnoses of irritable bladder (34%), cystitis (29%), prostatitis (19%) and/or urethritis (5%) were treated orally with a hydroethanolic fluid extract (1:1) of couch grass rhizome; the average dosage was 50-60 drops three times daily and the average duration 12 days. More than one complaint was diagnosed in 13% of the patients and a third of the patients were treated concomitantly with other drugs, mostly antibiotics. After treatment (for 12 days on average, with a minimum of 2 and maximum of 52 days; 7-14 days in 86% of patients), between 32% and 50% of the patients were free from initially documented symptoms (e.g. nycturia, frequent or painful micturition), and between 69% and 91% reported some relief of symptoms during the course of therapy [Hautmann 2000].

In an open, uncontrolled study 99 patients with diagnoses of prostatitic adenoma (48 male patients), chronic or acute prostatitis (38 male patients) or cystitis (12 female patients) were treated orally with a fluid extract (1:1, 20% V/V ethanol) of couch grass rhizome. The dosage was 60 drops three times daily and the duration of treatment 28-31 days. The treatment was evaluated from changes in various urinary parameters associated with infection and inflammation, and by subjective feeling of discomfort. For each of the parameters the results showed improvements of 40-100%. In the two groups of male patients the treatment was assessed as good to very good by 77.1 and 78.9% of the patients respectively, while 58.3% of the female patients considered the treatment very good [Barsom 1981].

Pharmacokinetic properties
No data available.

Preclinical safety data

Mutagenicity and carcinogenicity
A couch grass rhizome liquid extract (1:1 in 20% ethanol) showed no mutagenic activity in the Ames mutagenicity test in *Salmonella typhimurium* strains TA 98 and TA 100 [Schimmer 1994].

Clinical safety data
No adverse drug reactions were reported in an open surveillance study after oral intake by 313 patients of a hydroethanolic fluid extract (1:1) of couch grass rhizome, the majority taking 50-60 drops three times daily for about 12 days [Hautmann 2000].

In an open study involving 99 patients treated orally with a hydroethanolic fluid extract of couch grass rhizome, at 60 drops three times daily for an average of 30 days, the treatment was well tolerated by 96% of the patients. One patient withdrew due to gastrointestinal symptoms [Barsom 1981].

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

Front cover
Title page

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

GRINDELIAE HERBA

2015

Grindelia

DEFINITION

Grindelia consists of the dried flowering tops of *Grindelia robusta* Nutt., *Grindelia squarrosa* Dunal, *Grindelia humilis* Hook. et Arn. or *Grindelia camporum* Greene.

The material complies with the monograph of the Pharmacopée Française [Grindélia].

CONSTITUENTS

The characteristic constituents are resin (5-20% depending on the species) consisting mainly of diterpenic acids such as grindelic acid, 7,8-epoxygrindelic acid, 17-acetoxygrindelic acid [Didry 1982; Timmermann 1987; Stahl-Biskup 1998; Bradley 2006] and borneol [Fraternale 2007]; acetylenic compounds such as matricarianol and matricarianol acetate [Schulte 1964; Bohlmann 1965; Stahl-Biskup 1998; Bradley 2006]; flavonoids such as kaempferol 3-methyl ether and 3,7-dimethyl ether and various quercetin methyl ethers [Pinkas 1978; Didry 1982; Timmermann 1994; Stahl- Biskup 1998; Bradley 2006, Krenn 2009]; and triterpenoid saponins with grindelia sapogenin D, bayogenin and oleanolic acid as the sapogenins [Kreutzer 1990, 1995; Stahl-Biskup 1998; Bradley 2006;].

Other constituents include phenolic acids such as chlorogenic, *p*-hydroxybenzoic and *p*-coumaric acids [Pinkas 1978; Didry 1982; Stahl- Biskup 1998; Gehrmann 2002; Bradley 2006], approx. 5% of tannins [Stahl- Biskup 1998] and approx. 0.2% of essential oil consisting mainly of mono- and sesquiterpenes [Kaltenbach 1991; Schäfer 1993; Stahl-Biskup 1998; El-Shamy 2000; Bradley 2006; Fraternale 2007].

CLINICAL PARTICULARS

Therapeutic indications
Productive cough; catarrh of the upper respiratory tract [Grindelia 1983; Schimmer 1988; Stahl-Biskup 1998; Gehrmann 2002; Vanaclocha 2003; Bradley 2006; Schilcher 2010].

Efficacy in these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adult daily dose: 4-6 g of the drug as a 10% infusion [Herba Grindeliae 1953; Stahl-Biskup 1998; Gehrmann 2002; Vanaclocha 2003; Schilcher 2010]; 3-6 g of fluid extract (1:1, Erg-B 6) [Extractum Grindeliae fluidum 1953; Stahl-Biskup 1998; Vanaclocha 2003; Schilcher 2010]; 1.5-3 mL of tincture (1:10 or 1:5, ethanol 60-80% V/V) [Stahl-Biskup 1998; Gehrmann 2002; Vanaclocha 2003; Bradley 2006; Schilcher 2010]; other corresponding preparations.

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contra-indications
Known hypersensitivity to plants of the Compositae.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

E/S/C/O/P
MONOGRAPHS

Pregnancy and lactation
In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
In sensitive persons, irritation of the gastric mucosa might occur [Bradley 2006; Schilcher 2010].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antibacterial activity
Several ethanolic extracts [Pinkas 1978; Didry 1982; Schimmer 1988; Kreutzer 1990], resin fractions [Pinkas 1978; Didry 1982; Kreutzer 1990], a polyphenolic fraction [Pinkas 1978] and phenolic acids from grindelia [Didry 1982] inhibited the growth of various bacteria, including *Staphylococcus aureus* and *Bacillus subtilis*. No antibacterial activity was exhibited by isolated flavonoids [Schimmer 1988] or a saponin fraction [Kreutzer 1990].

Antifungal activity
In the plate diffusion test concentrations of up to 10 mg/plate of a mixture of bisdesmosidic grindelia saponins dose-dependently inhibited growth of the fungi *Candida tropicalis*, *Mucor mucedo*, *Trichoderma viride* and *Botrytis cinerea*. In another experiment, the same mixture inhibited the growth of three of these species with MIC values between 0.31 and 5.0 mg/plate (comparable to aescin) compared to 0.6 µg per plate for clotrimazole [Kreutzer 1995].

The essential oil of grindelia inhibited the growth of *Penicillium expansum*, *Aspergillus flavus*, *Trichoderma viride*, *Phomopsis* spp, *Monilia fructigena* and *Fusarium culmorum* by 9-83% in comparison with the control (econazole, 100%) when applied for 6 days at 2 µl per plate and by 71-83% at 30 µl per plate [Menghini 1995].

A methanolic extract at a concentration of 2 mg/mL agar, inhibited the growth of *Fusarium oxysporum*, *F. verticillioides*, *Penicillium expansum*, *P. brevicompactum*, *Aspergillus flavus* and *A. fumigatus* by 33-73% [Zabka 2012].

Antispasmodic activity
A fluid extract (1:1, ethanol 75%) and a polyphenolic fraction from grindelia exhibited mild antispasmodic activity on contractions of isolated guinea pig ileum. ED_{50} values for acetylcholine-, histamine-, serotonin- and bradykinin-induced contractions were respectively 150-200 µg/mL, 40 µg/mL, 10-50 µg/mL and 10-40 µg/mL for the fluid extract, and 150-200 µg/mL, 10-20 µg/mL, 10 µg/mL and 10 µg/mL for the polyphenolic fraction [Pinkas 1978]. However, this effect could not be confirmed in later research using a 50% V/V methanolic extract of grindelia; no antispasmodic activity was observed on spontaneous or acetylcholine- or barium chloride-induced contractions of isolated guinea pig ileum at concentrations up to 800 µg/mL [Izzo 1996].

Anti-inflammatory activity
Grindelia extracts of varying polarity have been tested in a neutrophil elastase assay. As observed earlier with various phenolic compounds [Melzig 2001], the extracts had a remarkable inhibitory effect (greater than 50%) at 1 mg dried extract/0.5 mL, indicating anti-inflammatory potential [Gehrmann 2002, 2003]. In the thrombin activity test the IC_{50} values of an acetone extract and a carbon dioxide extract were 330 and 500 µg/mL respectively [Gehrmann 2004].

In a murine macrophage model the inflammatory effects of *E.coli* lipopolysaccharide (LPS) were significantly mitigated by a methanolic extract of *Grindelia robusta*, including by reducing the expression of inducible NO synthase (iNOS), NO itself, TNF-α and IL-12 production (all at $p<0.05$), and IL-1β ($p<0.01$) [Verma 2010]. The extract also prevented LPS-mediated nuclear translocation of NF-κB [Verma 2010; La 2010].

Quercetin-3-methylether and 6-hydroxy-kaempferol-3,6-dimethylether inhibited the activity of neutrophil elastase with IC_{50} of 19 µM and 194 µM compared to a synthetic inhibitor (0.1 µM) [Krenn 2009].

In vivo experiments

Anti-inflammatory activity
A *Grindelia robusta* dry extract (80% ethanol) orally administered at 100 and 200 mg/kg b.w. dose-dependently inhibited carrageenan-induced rat paw oedema by 41% ($p<0.01$) and 63% ($p<0.001$) respectively, compared to 45% inhibition by indometacin at 5 mg/kg [Mascolo 1987].

The anti-inflammatory activity of a grindelia fluid extract (1:1, ethanol 75%) and a polyphenolic fraction was demonstrated in similar experiments. When administered intraperitoneally at 65 mg/kg 30 minutes before carrageenan injection, the extract inhibited rat paw oedema by 53% compared to 24% by lysine acetylsalicylate at 100 mg/kg and 30% by rutin at 100 mg/kg [Pinkas 1978].

Expectorant activity
In urethanized cats, rabbits and guinea pigs, respiratory tract fluid (RTF) was collected from the trachea 3 hours before and 4 hours after gastric administration of a grindelia fluid extract conforming to NF 7 (1942) at doses from 0.1 to 10 mL/kg body weight. The RTF output 2 hours after administration increased by 79% in cats while no effect was observed in rabbits or guinea pigs. Controls showed increases or decreases in RTF output of up to 30% over 4 hours [Boyd 1946].

Antispasmodic activity
A grindelia fluid extract (1:1, ethanol 75%) and a polyphenolic fraction showed no antispasmodic activity against histamine- or serotonin-induced bronchospasms after i.p. administration to guinea pigs. Only slight activity against acetylcholine- and bradykinin-induced bronchospasms was seen at higher doses (close to the toxic dose) [Pinkas 1978].

Clinical data
Grindelia preparations were used in earlier times to treat exanthema caused by intoxication with *Rhus toxicodendron* (poison oak) [Weiss 1966]. In a recent case study involving a woman suffering from poison oak dermatitis, application of a tincture (85% ethanol) from fresh flower buds of *Grindelia spp.* had an immediate effect, diminishing pruritus and decreasing transudation. The tincture mixed into a calendula cream base produced further relief [Canavan 2005].

Pharmacokinetic properties
No data available.

Preclinical safety data
No mortality occurred and no toxic effects were apparent in rats after a single oral dose of a *Grindelia robusta* dry extract (80% ethanol) at 2.5 g/kg b.w. [Mascolo 1987].

Intraperitoneal LD_{50} values in mice for a fluid extract and a polyphenolic fraction from grindelia were determined as 250 mg/kg and > 500 mg/kg b.w. respectively [Pincas 1978].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

HAMAMELIDIS AQUA 2012

Hamamelis Water

DEFINITION

Hamamelis water is a clear, colourless distillate prepared from recently cut and partially dried dormant twigs of *Hamamelis virginiana* L.

The material complies with the monograph of the United States Pharmacopeia [Witch hazel].

CONSTITUENTS

From 1 kg of partially dried dormant twigs the USP method of preparation yields approximately 1 litre (980 g) of hamamelis water containing 14-15% of ethanol (added after distillation) [Witch hazel]. Since it is obtained by a distillation process, the constituents are those of the volatile fraction, devoid of tannins [Hoffmann-Bohm 1993; Bradley 2006].

Distillation of fresh twigs yielded 0.09% of volatile fraction on the dry weight basis, consisting of aliphatic hydrocarbons (45.4%, predominantly alkanes), terpenes (approx. 30%; mainly sesquiterpenes such as α-ylangene and monoterpenes such as linalool), phenylpropanoids (7.5%) such as *trans*-anethole and eugenol, and aliphatic aldehydes (6.1%) and alcohols (5.3%); over 160 compounds were detected [Hartisch 1996; Engel 1998; Bradley 2006].

Distillation of fresh leaves yielded 0.13% of volatile fraction on the dry weight basis consisting of aliphatic hydrocarbons (62.8%, predominantly alkanes), terpenes (21.1% including 3.7% of linalool and 9.8% of the acyclic diterpene *trans*-phytol), aliphatic aldehydes (3.8%) and, fatty acids and fatty acid esters (3.6%); over 170 compounds were detected [Hartisch 1996; Engel 1998; Bradley 2006].

CLINICAL PARTICULARS

Therapeutic indications

External use
Treatment of bruises, skin irritations, sunburn, insect bites, external haemorrhoids [Sorkin 1980; Pfister 1981; Witch Hazel 1982; Swoboda 1991; Hoffmann-Bohm 1993; Korting 1993; Korting 1995; Hughes-Formella 1998; Falch 1999; Hughes-Formella 2002; Welzel 2005; Wolff 2007; Bradley 2006; Bühring 2008; Welzel 2009; Schilcher 2010,]. Minor inflammatory conditions of the skin and mucosa [Sorkin 1980; Witch Hazel 1982; Hoffmann-Bohm 1993; Korting 1993; Hughes-Formella 1998; Bradley 2006; Wolff 2007; Bühring 2008; Schilcher 2010].

Efficacy in these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

External use
For compresses on the skin: Hamamelis water undiluted or diluted 1:3 with water; in semi-solid preparations, 20-30% [Sorkin 1980; Pfister 1981; Moore 1989; Swoboda 1991; Hoffmann-Bohm 1993; Korting 1993; Korting 1995; Hughes-Formella 1998; Bradley 2006; Schilcher 2010]. Apply as often as required [Witch hazel 1982].
For mucosa: Hamamelis water undiluted or diluted with water, several times daily [Hoffmann-Bohm 1993; Bradley 2006; Schilcher 2010].

For children (0 to 16 years of age), application of the distillate diluted with water (1:4) is recommended [Bühring 2008].

Cream or ointment containing 5.35 or 6.25 % distillate (1:1-2; ethanol 6%), to be applied several times daily onto the respective areas [Welzel 2005; Wolff 2007; Welzel 2009]. The ointment is also suitable for children (from 4 weeks of age onwards) [Wolff 2007].

Method of administration
For local application.

Duration of administration
No restriction.

Contraindications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available.

Effects on ability to drive and use machines
None known.

Undesirable effects
Although the content of volatile fraction is very low, allergic reactions of the skin may occur in very rare cases [Witch Hazel 1982; Hoffmann-Bohm 1993; Granlund 1994].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In the following text, material prepared by distillation of partially dried dormant twigs of *Hamamelis virginiana* and complying with the monograph for Witch Hazel USP [Witch hazel] (or Hamamelis Water BPC 1973 [Hamamelis water], which is essentially similar) is described as 'hamamelis water'. Material prepared by distillation of fresh leaves and twigs of *Hamamelis virginiana* is described as 'hamamelis distillate'.

In vitro studies

Antimicrobial activity
In the agar diffusion test, a lotion consisting of 90 % hamamelis distillate and 5 % urea caused a weak inhibition of the growth of *Enterobacter aerogenes, Klebsiella pneumoniae, Staphylococcus aureus, Staphylococcus epidermidis, Staphylococcus saprophyticus, Staphylococcus xylosis, Candida albicans, Candida krusei, Candida tropicalis, Mallassezia furfur, Saccharomyces cerevisiae* and *Torulopsis glabrata*. The lotion without hamamelis failed to demonstrate antimicrobial activity [Gloor 2002].

Pharmacological studies in humans

Anti-inflammatory effect
The activity of hamamelis distillate against erythema was evaluated in creams with two concentrations of the drug (containing 0.64 mg or 2.56 mg per 100 g of carbonyl compounds, sometimes called "hamamelis ketones") and two different vehicles: oil-in-water emulsions, with or without phosphatidylcholine (PC). The effects were compared with those of hydrocortisone 1% cream, four base preparations and an untreated control area in two randomized, double-blind studies, each involving 24 healthy volunteers; in one study erythema was induced by UV irradiation, in the other by repeated stripping of the horny layer with adhesive tape. 24 hours after UV-irradiation noteworthy reductions in erythema were observed only after use of low dose hamamelis-PC cream and hydrocortisone 1% cream, more pronounced from the latter. Erythema 4-8 hours after stripping of the horny layer was significantly suppressed by hydrocortisone cream, while less pronounced but noteworthy reductions were observed with low and high dose hamamelis-PC creams. The results demonstrated some anti-inflammatory activity of hamamelis distillate in a PC-containing vehicle. A four-fold increase of drug concentration did not, however, increase activity [Korting 1993].

The anti-inflammatory effects of an aftersun lotion containing 10% of hamamelis water, in comparison with the corresponding vehicle, were tested in 30 healthy volunteers using a UV-B erythema test at four different UV-B intensities. Chromametry was used to compare the degrees of erythema in treated areas of skin with those in irradiated but untreated control areas 7, 24 and 48 hours after irradiation. Erythema suppression ranged from approx. 20% at 7 hours to 27% after 48 hours in the hamamelis water-treated areas, and from 10% at 7 hours to 12% after 48 hours in areas treated with the vehicle. Hamamelis water led to a highly significant reduction in erythema compared to the vehicle ($p = 0.00001$) and untreated, irradiated skin ($p = 0.00001$) [Hughes-Formella 1998].

Hamamelis distillate ointment applied to the skin of 22 healthy volunteers, and also 5 patients suffering from atopic neurodermitis and psoriasis, had a mild anti-inflammatory effect, causing a decrease in blood circulation as indicated by measurements of the thermal conductivity of the skin [Sorkin 1980].

Three different lotions containing 10% hamamelis distillate (no further details available), two vehicles (distillate replaced by ethanol 15% or by water, respectively), dimethindene maleate 0.1 % gel, hydrocortisone 1 % cream and 0.25 % lotion were tested in 40 light-skinned volunteers undergoing a modified UV erythema test with UV dosages of 1.2, 1.4 and 1.7 MED. The test preparations were applied occlusively over a 48-hour period following irradiation. Differences in chromametric observations after 24, 48 and 72 hours were calculated as delta a* values. In erythema suppression, the hydrocortisone preparations were most effective (delta a* between 0.3 and 7.3). An anti-inflammatory effect was seen for all hamamelis preparations (delta a* between 1.8 and 8.2) as well as for the vehicle (delta a* between 1.7 and 8.6), compared to the irradiated untreated control (delta a* between 2.6 and 8.3). Compared to the erythema in the control group, the percentage suppression by the hamamelis lotions ranged from 1-6 % at 24 hours to 23-30% at 72 hours [Hughes-Formella 2002].

Antimicrobial effect
The antimicrobial activity of a lotion consisting of 90 % hamamelis distillate and 5 % urea was examined in an occlusion test (test areas of 4cm x 4cm on the subjects back) in 15 healthy volunteers. This test was followed by an expanded flora test in order to determine the same effect for a higher level of bacterial colonization. Bacteriological testing was performed 24 or 48 hours after starting the test, respectively. The lotion showed significant antimicrobial activity on aerobic bacteria in both tests as compared to untreated subjects ($p<0.001$), and appeared to be more effective than the lotion without hamamelis

distillate (significant p< 0.01 in the expanded flora test).No significant differences were found against anaerobic bacteria [Gloor 2002].

Clinical studies

Analgesic effect
In a randomised, open study involving 300 postnatal mothers, three topical agents were evaluated for their efficacy in achieving analgesia for episiotomy pain following instrumental (forceps) vaginal delivery: hamamelis water, or ice or a foam containing hydrocortisone acetate 1% and pramoxine hydrochloride 1%. Oral analgesics were permitted and taken to the same extent in all three groups. According to data collected from 266 women, the three topical agents were equally effective in achieving analgesia, with no significant differences on day 1, although from subjective and professional assessment about one-third of all mothers derived little benefit from any agent. On days 3 and 5 ice tended to be better. 126 mothers were further assessed after 6 weeks; no differences were found between the three groups in terms of healing, pain and intercourse patterns [Moore 1989].

Dermatological conditions
In a randomized, double-blind study, 22 patients suffering from atopic dermatitis were treated on one forearm with an ointment containing hamamelis distillate (250 mg/g) and on the other forearm with bufexamac ointment (50 mg/g) three times daily for 3 weeks. From assessment of symptoms such as reddening, scaling, lichenification, itching and infiltration, no statistical difference was observed between the two treatments; both forearms showed clear improvements [Swoboda 1991].

In a randomized, double-blind, paired trial, 72 patients suffering from moderately severe atopic eczema were treated for 2 weeks with a cream containing hamamelis distillate (5.35 g/100g), or the corresponding vehicle-only cream, or hydrocortisone 0.5% cream. The reduction in total scores for three basic criteria, itching, erythema and scaling, was significantly greater ($p<0.0001$) following application of hydrocortisone in comparison with hamamelis distillate, while the score for the hamamelis preparation did not differ from that of the vehicle [Korting 1995].

In another double-blind study, 116 patients with eczema of different aetiologies were treated with either ointment A containing hamamelis distillate (25 g/100g) or hamamelis preparation B (not defined, but presumed to contain distillate) as a control, or both preparations (applied to different hands), several times daily for 4-6 weeks. Improvements in the symptoms of itching, burning sensations, infiltration, reddening and scaling were observed in the majority of cases with both preparations; ointment A gave superior results with endogenous eczema but not with toxic-degenerative eczema [Pfister 1981].

A preparation containing 90% hamamelis water USP and 5 % urea was given as a compress twice daily to 39 patients suffering from seborrhoeic dermatitis. Scaling and erythema decreased, and in 80 % of the patients symptoms disappeared completely or almost completely after 8 weeks. Similar preparations with different lipid contents were applied as the only treatment to 40 otherwise pre-treated patients with dry and itching skin conditions. Symptoms disappeared or improved after 8 weeks in 65 % of the patients. Only 4 patients had to continue with steroids [Falch 1999].

In an open-label study 89 patients, of minimum 55 years of age, suffering from dry skin (lipid content less than 6 µg sebum/cm^2 skin, humidity ≤55 arbitrary units) received an ointment containing 6.25 % hamamelis distillate (1:1-2 distilled with ethanol 6% m/m) which was applied to the dry areas twice daily for 4 weeks. After 4 weeks the mean lipid content increased significantly from 2.4 to 59.8 µg sebum/cm^2 ($p<0.0001$), the mean skin humidity from 47.6 to 55.6 arbitrary units ($p<0.0001$). Scaling and fissures measured by visual scores were also reduced significantly ($p<0.0001$), and symptoms like skin tension, roughness and itching also improved ($p<0.0001$) [Welzel 2005].

In a similar open study, 35 patients suffering from various drug-induced skin symptoms such as dry skin, scaling, fissures, roughness and itching received the same preparation twice daily for 4 weeks. After this period, the mean lipid content increased significantly from 0.69 to 60.91 µg sebum/cm^2 ($p<0.001$), the mean skin humidity from 43.53 to 45.12 arbitrary units. Scaling and fissures measured by visual scores were also reduced ($p<0.001$), and symptoms like skin tension, roughness and itching improved ($p<0.001$) [Welzel 2009].

In a multicentre, prospective study in 309 children (between 27 days and 11 years of age) suffering from superficial skin injuries, local inflammations of the skin or diaper dermatitis, 231 children received an ointment containing 6.25 % hamamelis distillate (1:1-2 distilled with ethanol 6% m/m) and 78 children a dexpanthenol ointment, each at an individual dose for 7 to 10 days. For all diagnoses a significant ($p<0.0001$) improvement was seen between the beginning and the end of therapy. 83.5% of the physicians and 83.1 % of the parents assessed the efficacy of Hamamelis ointment as very good or good, the efficacy being comparable to dexpanthenol [Wolff 2007].

Pharmacokinetic properties
No data available.

Preclinical safety data
Based on studies performed in F344 rats and B6C3F1 mice which were topically administered 50 or 100% hamamelis water within the National Cancer Institute's (NCI) National Toxicology Program (NTP), hamamelis water is interpreted as showing no carcinogenic effects [Hasemann 1984].

Clinical safety data
In an open-label study in 89 patients as well as in a similar open study in 35 patients with various symptoms related to dry skin who received an ointment containing 6.25 % hamamelis distillate (1:1-2 distilled with ethanol 6% m/m) twice daily for 4 weeks, no serious adverse events were reported that might have had a causal relationship with the medication [Welzel 2005, Welzel 2009].

In a multicentre, prospective study in 231 children (between 27 days and 11 years of age) who received an ointment containing 6.25 g hamamelis distillate (1:1-2 distilled with ethanol 6% m/m) at an individual dose for 7 to 10 days, 99.1% of the physicians and 98.2 % of the parents assessed the tolerability of Hamamelis ointment as very good or good [Wolff 2007].

A preparation containing 90% hamamelis water USP and 5 % urea was given as a compress twice daily to 50 patients suffering from peri-anal dermatitis, and 50 patients suffering from eczematoid dermatitis. No allergic or other intolerance reactions were found [Falch 1999].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

HAMAMELIDIS CORTEX 2012

Hamamelis Bark

DEFINITION

Hamamelis bark consists of the dried bark from stems and branches of *Hamamelis virginiana* L., collected in spring. It contains not less than 4.0% of hide powder-precipitable tannins, expressed as pyrogallol ($C_6H_6O_3$; M_r 126.1) and calculated with reference to the dried drug.

The material complies with the monograph of the Deutscher Arzneimittel-Codex [Hamamelisrinde] or the British Herbal Pharmacopoeia [Hamamelis Bark].

CONSTITUENTS

The main characteristic constituent is hamamelitannin, a mixture of the α- and β-forms of 2',5-di-*O*-galloylhamamelose [Mayer 1965; Friedrich 1974; Vennat 1988; Hoffmann-Bohm 1993; Haberland 1994; Hartisch 1996; Wang 2003; Bradley 2006]. Proanthocyanidins are also present including: procyanidin dimers such as catechin-(4α→8)-catechin, 3-*O*-galloyl-epicatechin-(4β→8)-catechin and epicatechin-(4β→8)-catechin-3-*O*-(4-hydroxy)benzoate [Friedrich 1974; Vennat 1988; Hartisch 1996a,b]; prodelphinidins such as epigallocatechin-(4β→8)-catechin, 3-*O*-galloyl epigallocatechin-(4β→8)-catechin and 3-*O*-galloyl epigallocatechin-(4β→8)-gallocatechin [Hartisch 1996a,b; Bradley 2006]; and proanthocyanidin oligomers consisting of 4-9 catechin/gallocatechin units, some of which are 3-*O*-galloylated [Hartisch 1996b; Hartisch 1997; Dauer 1998; Dauer 2003b; Bradley 2006].

Other constituents include flavan-3-ols such as (+)-catechin, (+)-gallocatechin, (–)-epicatechin-3-*O*-gallate, and (–)-epigallocatechin-3-*O*-gallate [Friedrich 1974; Hartisch 1996a; Wang 2003; Bradley 2006]; di-and tri-*O*-galloyl-hamameloses and related 4-hydroxybenzoates [Haberland 1994; Hartisch 1996a,b], pentagalloyl glucose [Friedrich 1974], gallic acid [Friedrich 1974; Vennat 1988; Wang 2003; Bradley 2006] and about 0.1% of volatile oil [Hoffmann-Bohm 1993; Bradley 2006].

CLINICAL PARTICULARS

Therapeutic indications

Internal use
Inflammation of mucous membranes of the oral cavity [Hoffmann-Bohm 1993; Laux 1993; Hiller 2009].
Short-term symptomatic treatment of diarrhoea [Hamamelis Bark; Laux 1993; Bradley 2006].

External use
Haemorrhoids [Reynolds 1982; Van Hellemont 1988; Hoffmann-Bohm 1993; Laux 1993; Bradley 2006, Schilcher 2007; Hiller 2009], minor injuries and local inflammations of the skin [Reynolds 1982; Hoffmann-Bohm 1993; Laux 1993; Hörmann 1994; Millikan 2003; Bradley 2006; Bühring 2008; Hiller 2009; Schilcher 2010].
Symptomatic treatment of problems related to varicose veins, such as painful and heavy legs [Van Hellemont 1988; Hoffmann-Bohm 1993; Bradley 2006; Hiller 2009; Schilcher 2010].

Efficacy in these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Internal use
2-10 g of the drug daily as a decoction, used as a mouthwash [Van Hellemont 1988; Hoffmann-Bohm 1993; Bradley 2006; Hiller 2009; Schilcher 2010], or

2-3 g daily as a tea [Bradley 2006; Hiller 2009].
2-4 ml of tincture, used diluted as a mouthwash 3 times daily [Hamameils Bark; Bradley 2006].
Other preparations: the equivalent of 0.1-1 g of the drug, 1-3 times daily [Hoffmann-Bohm 1993; Bradley 2006; Hiller 2009; Schilcher 2010].

External use
5-10 g of the drug as a decoction in 250 ml of water [Hoffmann-Bohm 1993; Bradley 2006; Bühring 2008].
Use of the decoction (e.g. for compresses and baths) is also recommended in children [Bühring 2008].
Extracts in semi-solid or liquid preparations corresponding to 20-30% of the drug [Hoffmann-Bohm 1993].

Method of administration
For oral administration or local application.

Duration of administration
No restriction. Medical advice should be sought if diarrhoea persists for more than 3 days.

Contraindications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used internally during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
In sensitive persons, stomach irritation may occasionally occur after intake of hamamelis bark preparations [Hoffmann-Bohm 1993]. Chamomile-sensitive persons might also react to hamamelis preparations after topical application [Paulsen 2008].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro studies

Astringent effect
The astringent effect of a tincture (1:3; 62% ethanol) prepared from fresh hamamelis bark was demonstrated with hide powder [Gracza 1987].

Antibacterial activity
Hamamelitannin did not affect growth of *Staphylococcus aureus* and *Staphylococcus epidermidis* even at high concentrations, but significantly ($p<0.05$) down-regulated RNAIII production in reporter cells at a dose of 50 µg in both strains. Furthermore, it inhibited bacterial cell attachment of both strains in a concentration-dependent manner and reduced delta-haemolysin production in a Western blotting test. [Kiran 2008].

Cytotoxic activity
After 4 days of incubation, polyphenols isolated from hamamelis bark showed moderate cytotoxicity to GLC_4 lung carcinoma and COLO 320 cells. The 3-*O*-galloyl compounds were more effective than other compounds. IC_{50} values of galloyl compounds were between 38 µM and 110 µM for GLC_4 and between 18.3 µM and 90.8 µM for COLO 320 cells; almost complete inhibition of growth was observed at 200 µM [Hartisch 1996a].

Polymeric proanthocyanidins from Hamamelis bark, in contrast to polysaccharides thereof, significantly ($p<0.1$, $p<0.05$) increased proliferation of human keratinocytes after 9 days of incubation at doses of 1 and 10µg/ml, respectively. There was no influence on the differentiation towards cornified cells [Deters 2001].

Polyphenolic fractions from Hamamelis bark (containing catechins, proanthocyanidins and gallotannins) inhibited cell proliferation in HT29 and HCT116 human colon cancer cell lines with average IC_{50} values of 28 and 29 µg/ml, respectively; the highly galloylated fractions being the most effective. In the same way, these fractions were able to arrest different phases of the cell cycle and to induce early apoptosis in HT29 cancer cells [Lizzárraga 2008].

Fractions rich in pyrogallol-containing polyphenols (proanthocyanidins, gallotannins, gallates) protected red blood cells from free radical-induced haemolysis in a dose-dependent manner with IC_{50} values between 21.5 and 24.5 µg/ml. They were mildly cytotoxic to HaCat keratinocytes (IC_{50} between 38 and 68 µg/ml) and 3T3 fibroblasts (IC_{50} between 33 and 51 µg/ml), and also inhibited the proliferation of tumoural SK-Mel 28 melanoma cells (IC_{50} between 26 and 39 µg/ml) [Touriño 2008].

Cell and DNA-protective effects
Catechin, hamamelitannin and two proanthocyanidin fractions prepared from Hamamelis bark were investigated in human Hep G2 cell lines using single cell gel electrophoresis (SCGE) for the detection of DNA-damage. Catechin and a low-molecular weight proanthocyandin fraction (W_M) caused only slight increases in DNA-migration up to concentrations of 166 µg/ml whereas hamamelitannin and the proanthocyandin fraction with higher molecular weight (W_A) dose-independently led to a two-fold enhancement of DNA-migration at the same concentrations. Treatment of the cells with the test compounds in a dose-range of 2–166 µg/ml prior to the exposure to 10 µM (2.5 µg/ml) benzo(a)pyrene (B(a)P) led to a significant reduction of induced DNA damage. The inhibitory effects of proanthocyanidins were stronger than those of catechin and hamamelitannin; the lowest effective concentrations were about 2 µg/ml [Dauer 2003a].

Hamamelitannin at concentrations of 1 to 100 µM inhibited TNF-mediated cell death and DNA fragmentation in a dose-dependent manner with a 100% protection at concentrations higher than 10µM. The protective effect was comparable to that of epigallocatechin gallate, and higher than gallic acid with less than 40% protection. However, hamamelitannin at concentrations of 1 to 100 µM did not alter the TNF-induced upregulation of endothelial adhesiveness [Habtemariam 2002].

Anti-inflammatory effects
In the lyso-PAF:acetyl-CoA acetyltransferase assay, hamamelitannin proved to be ineffective [Hartisch 1997], but in the same assay a proanthocyanidin oligomer isolated from hamamelis bark showed inhibitory potential [Hartisch 1996a, 1997]. A range of compounds from hamamelis bark had an inhibitory effect on 5-lipoxygenase (from a cytosol fraction of RBL-1 cells), galloyl compounds showing greater potency than

other substances; hamamelitannin had the strongest effect with an IC_{50} of 1.0 µM [Hartisch 1996a, 1997].

Anti-inflammatory effects of polyphenols isolated from hamamelis stem and twig bark were evaluated in human polymorphonucleocytes (PMNs) and human macrophages. With the exception of hamamelitannin, all the tested substances inhibited the synthesis of platelet activating factor (PAF) in human PMNs. Dimeric galloylated proanthocyanidins showed the strongest effects with IC_{50} values of 7.8 and 6.4 µM. The synthesis of leukotriene B_4 (LTB_4) in PMNs was inhibited by the tested substances. Oligomeric proanthocyanidins had stronger activity (IC_{50}: 1.5 µM) than hamamelitannin, which had the weakest effect (IC_{50}: 12.5 µM). The polyphenols were shown to inhibit zymosan-induced luminol-dependent chemiluminescence in human macrophages, with galloylated proanthocyanidins having stronger effects (IC_{50}: 2.3 and 2.0 µM) than hamamelitannin (IC_{50}: 10.5 µM) [Hartisch 1996a].

Antiviral activity
Hamamelitannin and fractions obtained by ultrafiltration from a hydroethanolic extract of hamamelis bark exhibited antiviral activity against *Herpes simplex* virus type 1 in monkey kidney cells. After 2-3 days the ED_{50} of hamamelitannin for antiviral activity was 26 µg/ml, compared to 6.3 µg/ml for a fraction consisting mainly of oligomeric to polymeric proanthocyanidins and 0.42 µmol/ml for acyclovir as a positive control [Erdelmeier 1996].

Radical-scavenging effects
A dry 50%-ethanolic extract from hamamelis bark exhibited active-oxygen scavenging activity, determined by an electron spin resonance (ESR) spin-trapping technique, with IC_{50} values of 0.17 µg/ml for superoxide anions, 7.79 µg/ml for hydroxyl radicals and 44.08 µg/ml for singlet oxygens, compared to 4.10, 3.30 and 21.18 µg/ml respectively for ascorbic acid. The extract at 50 µg/ml also protected murine dermal fibroblasts from cell damage induced by active-oxygen, increasing the survival rate to 69.0% ($p<0.01$) compared to about 15% for the control [Masaki 1995].

A suppressive effect of hamamelitannin against depolymerization of hyaluronic acid (induced by a xanthine/xanthine oxidase system) was demonstrated by measuring the viscosity of a 0.9 mg/ml solution; the inhibitory rate was 73.8% for hamamelitannin compared to 24.7% for ascorbic acid and 84.4% for superoxide dismutase [Masaki 1993].

Polyphenolic fractions from Hamamelis bark induced a dose-dependent protection against DNA damage in the hydroxyl radical system at doses from 10-100 µM, and showed oxygen radical scavenging activity as detected by (ESR) spectroscopy, being most effective at a dose of 50µM [Lizzárraga 2008].

The radical scavenging properties of hamamelitannin and gallic acid were evaluated in further experiments using ESR spin-trapping. For superoxide anion scavenging, the IC_{50} values were 1.31 µM for hamamelitannin and 1.01 µM for gallic acid, compared to 23.31 µM for ascorbic acid [Masaki 1993, 1994, 1995]. In hydroxyl radical scavenging, hamamelitannin gave the lowest IC_{50} of 5.46 µM, compared to 78.04 µM for gallic acid and 86.46 µM for propyl gallate (a well-known antioxidant). In singlet oxygen scavenging, the IC_{50} values of hamamelitannin and gallic acid were 45.51 µM and 69.81 µM respectively, compared to 66.66 µM for propyl gallate [Masaki 1994].

Fractions rich in pyrogallol-containing polyphenols (proanthocyanidins, gallotannins, gallates) were strong free radical scavengers against ABTS (6mmol Trolox equiv/g), DPPH (ED_{50} between 26.1 and 58.8 µg fraction/µmol radical) and tris-(2,4,6-trichloro-3,5-dinitrophenyl)-methyl HNTTM radical (ED_{50} between 38.2 and 86.2 µg/µmol) [Touriño 2008]. In a similar experiment, fractions of polyphenols with different degrees of galloylation and polymerization demonstrated protection against erythrocyte lipid peroxidation, haemolysis and 3T3 cytotoxicity caused by H_2O_2 at concentrations of 25, 50 and 75 µg/mL [Mitjans 2011].

The ability of polyphenolic fractions from Hamamelis bark to reduce the α-tocopheroxyl radical was investigated in a homogenous hexane system and a phospholipid-like system based on sodium dodecyl sulfate (SDS) micelles. Tocopheroxyl radicals were monitored and quantified by ESR spectroscopy in the absence and presence of phenolic substances. Polyphenolic fractions from hamamelis reduced 80% of α-tocopheroxyl radicals in the hexane system and approximately 90% in SDS micelles [Pazos 2009].

Hamamelitannin was also found to have antioxidative and scavenging activities against organic radicals such as 1,1-diphenyl-2-picrylhydrazyl (DPPH). Expressed as an index number (the number of mol required to scavenge one mol of DPPH), hamamelitannin and gallic acid gave results of 9.4 and 8.8 respectively, compared to 2.2 for DL-α-tocopherol and 2.0 for ascorbic acid [Masaki 1994].

The protective activities of hamamelitannin and gallic acid on cell damage induced by superoxide anion radicals were evaluated in a cell-culture system using murine fibroblasts. Hamamelitannin and gallic acid showed significant protective activity against superoxide radicals at minimum concentrations of 50 µM and 100 µM respectively ($p<0.01$) [Masaki 1994, 1995]; at 50 µM, hamamelitannin enhanced the survival of fibroblasts to 52.4% compared to 36.9% for the control [Masaki 1995]. Pre-treatment of fibroblasts with hamamelitannin at 200 µM for 24 hours at 37°C before exposure to superoxide anions increased cell survival to 63.8%, compared to 25.4% for gallic acid and 19.0% for the control. Further observations confirmed that hamamelitannin is superior to gallic acid in protecting against cell damage induced by superoxide anions and suggested that the high affinity of hamamelitannin for cells or membranes may be an important factor for protecting cells against active oxygen species [Masaki 1995].

In contrast, against cell damage induced in murine fibroblasts by hydroxyl radicals, hamamelitannin showed protective activity at a minimum concentration of 500 µM whereas gallic acid was effective at 50 µM. Against cell damage induced by singlet oxygens hamamelitannin at 100 µM enhanced survival to 80.6% ($p<0.01$), while gallic acid had no significant effect at 100 µM and required 500 µM to enhance survival to 98.6% ($p<0.01$) compared to 60.4% survival for controls [Masaki 1994].

Hamamelitannin and a fraction of molecular weight < 3 kDa obtained by ultrafiltration from a hydroethanolic hamamelis bark extract were found to have greater radical scavenging activity (ED_{50} values of 29 and 80 ng/ml respectively) than a higher molecular weight procyanidin fraction (≥ 3 kDa; ED_{50} 160 ng/ml) as quantified by the emission of chemiluminescence during autoxidation of mouse brain lipids [Erdelmeier 1996].

An extract from Hamamelis leaf and bark (ethanol 60%) showed antioxidant activity in the ABTS assay in a dilution of 1:10000 with an activity equivalent to 40 µM of trolox [Pereira da Silva A 2000].

Hamamelitannin showed strong peroxynitrite (ONOO-)-scavenging properties at a concentration of 5.0 µg/ml in an

experiment using dihydrorhodamine 123 as a substrate for oxidation [Choi 2002].

Antimutagenic activity
In the Ames mutagenicity test, a tincture (1:5) and a methanolic extract (1:5) of hamamelis bark dose-dependently inhibited 2-nitrofluorene-induced mutagenicity in *Salmonella typhimurium* TA98, by 60% and 54% respectively at 100 µl/plate. It was demonstrated that the antimutagenic effect increased with increasing degree of polymerisation of proanthocyanidins, the most active fraction consisting of catechin and gallocatechin oligomers with an average degree of polymerization of 9.2 [Dauer 1998].

In vivo studies

Anti-inflammatory effect
A hydroethanolic extract of hamamelis bark showed a significant anti-inflammatory effect (43% inhibition of oedema; $p<0.05$) in the croton oil ear oedema test in mice when applied topically at 250 µg per ear. After ultrafiltration of the crude extract, this effect was shown to be mainly due to proanthocyanidins of molecular weight ≥ 3 kDa (69% inhibition at 250 µg per ear; $p<0.05$); proanthocyanidins of lower molecular weight had no effect and hamamelitannin produced only 7% inhibition [Erdelmeier 1996].

Anti-bacterial effect
Preincubating grafts contaminated with *Staphylococcus aureus* and *Staphylococcus epidermidis* with hamamelitannin for 7 days prevented infections in male Wistar rats (n=10). No bacteria were found after preincubation with >20µg oh hamamelitannin, while the bacterial load in the untreated control group was 10^7 CFU/ml. In a parallel experiment, grafts soaked with increasing hamamelitannin concentrations were implanted into the animals and bacteria injected onto the graft. Hamamelitannin caused a significant ($p<0.05$) decrease in bacterial load, whereas in the untreated control group 10^7 CFU/ml were found. No bacterial load was found in grafts soaked with 30 mg/l hamamelitannin [Kiran 2008].

Pharmacological studies in humans
The irritant sodium lauryl sulphate was applied at 0.5% twice daily for 3 days under patch occlusion to seven healthy volunteers who also received a semi-solid preparation containing 1 % of hamamelis procyanidin or placebo. Treatment with the preparation reduced increased transepidermal water loss by 53% as compared to placebo (45%). The treatment also increased the clinical scoring of dermal inflammation better than placebo and reduced erythema formation [Deters 2001].

Pharmacokinetic properties
No data available.

Preclinical safety data
No data available.

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

HAMAMELIDIS FOLIUM 2012

Hamamelis Leaf

DEFINITION

Hamamelis leaf consists of the whole or cut, dried leaf of *Hamamelis virginiana* L. It contains not less than 3 per cent of tannins, expressed as pyrogallol ($C_6H_6O_3$; M_r 126.1) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Hamamelis Leaf].

CONSTITUENTS

The main characteristic constituents are tannins (5-10%) [Egerer 2005; Bradley 2006; Hiller 2009], including condensed tannins (mainly proanthocyanidin oligomers with catechin and/or gallocatechin units) and hydrolysable gallotannins, notably a small amount of hamamelitannin [Vennat 1988, 1992; Scholz 1994; Wang 2003; Bradley 2006; Hiller 2009, Duckstein 2011]. (+)-Catechin, (+)-gallocatechin, (–)-epicatechingallate and (–)-epigallocatechingallate are also present [Friedrich 1974; Bradley 2006, Duckstein 2011].

Other constituents include flavonoids such as kaempferol, quercetin, quercitrin, isoquercitrin and myricetin; phenolic acids such as caffeic acid and gallic acid [Bernard 1977; Vennat 1992; Hoffmann-Bohm 1993; Laux 1993; Bradley 2006; Hiller 2009, Duckstein 2011]; and a volatile fraction, 0.04-0.14% [Messerschmidt 1971; Bradley 2006; Hiller 2009], containing aliphatic hydrocarbons (63%), mono- and sesquiterpenes (11%) and aldehydes and ketones (4.6%) among over 170 compounds detected [Engel 1998; Bradley 2006].

CLINICAL PARTICULARS

Therapeutic indications

Internal use
Symptomatic treatment of complaints related to varicose veins, such as painful and heavy legs, and of haemorrhoids [Bernard 1977; Van Hellemont 1988; Hoffmann-Bohm 1993; Laux 1993; Hörmann 1994; MacKay 2001; Egerer 2005; Hiller 2009; Schilcher 2010].

External use
Bruises, sprains and minor injuries of the skin [Hoffmann-Bohm 1993; Laux 1993; Bradley 2006; Bühring 2008; Hiller 2009].
Local inflammations of the skin and mucosa [Bernard 1977; Hoffmann-Bohm 1993; Laux 1993; Millikan 2003; Bradley 2006; Bühring 2008; Hiller 2009; Schilcher 2010].
Haemorrhoids [Hoffmann-Bohm 1993; Laux 1993; Hamamelis Leaf (BHP) 1983; Bradley 2006; Hiller 2009; Schilcher 2010].
Relief of the symptoms of neurodermitis atopica [Wokalek 1993; Bradley 2006] and feeling of heavy legs [Hoffmann-Bohm 1993].

Efficacy in these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Internal use
Adults: 2-3 g of drug as infusion [Hoffmann-Bohm 1993; Bradley 2006; Hiller 2009] or 2-4 ml of liquid extract (1:1, 45% ethanol), three times daily [Hamamelis Leaf (BHP) 1983; Bradley 2006].

External use
Extracts in semisolid or liquid preparations, containing 5-10% of drug [Hoffmann-Bohm 1993; Bradley 2006; Schilcher 2010].

E/S/C/O/P MONOGRAPHS

Decoctions, 5-10 g of drug per 250 ml water for compresses or washes [Hoffmann-Bohm 1993; Bradley 2006; Hiller 2009; Schilcher 2010].
Suppositories containing 200 mg of dried extract, 1-2 per day [Bradley 2006; Schilcher 2010].
Ointment containing 10% of liquid extract [Bradley 2006; Schilcher 2010].
The use of the decoction (e.g. for compresses or bathes) is also recommended in children [Bühring 2008]

Method of administration
For oral administration and topical application.

Duration of administration
If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the drug should not be used internally during pregnancy without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
In sensitive patients there is a possibility of stomach upsets after taking hamamelis leaf preparations [Hoffmann-Bohm 1993]. Chamomile-sensitive persons might also react to hamamelis preparations after topical application [Paulsen 2008].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments
A lyophilized 10% decoction and a methanolic dry extract of Hamamelis leaf both exerted antibacterial activity on various periodonthopathic bacteria such as *Eikenella corrodens*, *Actinomyces odontolyticus*, *Porphyromonas gingivalis* and *Prevotella* spp.; the methanolic extract being more potent with MICs from 32 µg/mL onwards [Iauk 2003].

An extract from Hamamelis leaf and bark (ethanol 60%) showed antioxidant activity in the ABTS assay in a dilution of 1:10000 with an activity equivalent to 40 µM of trolox [Pereira da Silva A 2000].

In vivo experiments
Venotonic activity was demonstrated in experiments where the dried residue (300 mg) from aqueous or various hydroethanolic extracts of hamamelis leaf was added to one litre of an isotonic dextran/water (60 g/litre) solution. This was perfused at constant pressure into the arteries of the hind quarters of rabbits (45-100 drops/min). Venoconstriction, measured in terms of output on the venous side, was reduced by up to 60-70% depending on the type of extract [Bernard 1972].

A dry 70%-ethanolic extract of hamamelis leaf, administered orally to rats at 200 mg/kg daily for 19 days, significantly inhibited paw swelling ($p<0.05$) in the chronic phase of adjuvant-induced arthritis but was not active against the acute phase of oedema [Duwiejua 1994].

Pharmacological studies in humans
In a study conducted on 30 human volunteers, topical application of a hydroglycolic extract of hamamelis leaf produced a significant reduction in skin temperature ($p<0.001$ after 5 min; $p<0.03$ after 60 min), which was interpreted as a vasoconstrictor effect [Diemunsch 1987].

Clinical studies
In a pilot study involving cases of neurodermitis atopica, a cream containing hamamelis leaf extract was applied twice daily for 2 weeks in six groups of patients:
- Group I consisted of 7 children aged from 6 to 14 years with atopic neurodermitis on the feet (chilblains). After treatment the condition had considerably improved in all the patients.
- Group II consisted of 5 children with eczema in the flexure of the joints in subacute and chronic forms. After treatment 3 children were completely cured; in 2 children a considerable reduction of the inflamed condition and a clear reduction of the itch was noted.
- In Group III, which consisted of 10 adults with eczema in the flexure of the joints, 7 cases showed a good response and in three cases there was reasonable improvement.
- Group IV consisted of 5 adults with eczema of the neck and throat. 3 cases were completely cured and a remarkable reduction in symptoms was noted in the remaining 2 cases.
- Group V consisted of 3 adults with atopic eczema of the trunk. In one patient there was extensive healing and in the others a noticeable reduction of symptoms.
- Group VI consisted of 2 cases of atopic xerodermia. Following twice daily application of the cream, there was an improvement of the skin barrier situation and a clear diminution of desquamating pruritus in both cases [Wokalek 1993].

Pharmacokinetic properties
No data available.

Preclinical safety data

Carcinogenicity
NIH black rats (15 male and 15 female) were injected subcutaneously with a lyophilised aqueous leaf extract at a dosage of 10 mg (dissolved in 0.5 ml of saline solution) weekly for a period of 78 weeks; 30 animals were injected with saline solution only. The animals were observed for a period of 90 weeks. After about 73 weeks, three of the male rats developed malignant mesenchymoma, while in the control animals no tumours developed. The tumour rate was not considered to be significant [Hoffmann-Bohm 1993].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)

HELICHRYSI FLOS

2019

Sandy Everlasting Flower

DEFINITION

Sandy everlasting flower consists of the whole or cut, dried, fully opened flowers of *Helichrysum arenarium* (L.) Moench. It contains not less than 0.6 percent of flavonoids, calculated as hyperoside ($C_{21}H_{20}O_{12}$, Mr. 467.4) with reference to dried drug [DAC/NRF] or calculated as quercetin ($C_{15}H_{10}O_{7}$, M_r 302.24) with reference to dried drug [Farmakopea Polska].

The material complies with the monograph of the Farmakopea Polska or DAC/NRF.

CONSTITUENTS

The main constituents are the flavonoids naringenin, luteolin, quercetin, kaempferol, apigenin and their glucosides, isosalipuroside [Mericli 1986, Jarzycka 2013, Czinner 2000], hispidulin [Babotă 2018], essential oil containing mainly sesquiterpene hydrocarbons, oxygenated monoterpenes, δ-cadinene trans-caryophyllene and carvacrol [Lemberkovics 2001, Radušiene 2008], coumarins such as umbelliferone, scopoletin, helichrysin A, helichrysin B, aesculetin [Derkach 1986], phenolic acids such as caffeic acid, shikimic acid [Dombrowicz 1992, Czinner 2000], dicaffeoylquinic acid derivatives, chlorogenic acid, crypto-chlorogenic acid, neochlorogenic acid [Jarzycka 2013], everlastosides [Morikawa 2009a], arenariumosides [Morikawa 2009b], tumoroside and arenariumosides in the form of dimeric dihydrochalcone glycosides [Morikawa 2015].

CLINICAL PARTICULARS

Therapeutic indications
Symptomatic treatment of digestive disorders [Ożarowski 1987; Teuscher 2016].

In these indications, the efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adults:
1.5 g of comminuted herbal substance in 150-250 mL of water as a decoction for 10 minutes, 2 - 3 times daily, or 3 g of comminuted herbal substance, in 150-200 mL of boiling water, as an infusion, 1 - 3 times daily [Ożarowski 1986, Teuscher 2016].

Method of administration
For oral administration.

Duration of use
No restriction.

Contra-indications
Known sensitivity to members of the Asteraceae (Compositae).

Special warnings and precautions for use
None required.

Interaction with other medicinal products and other forms of interaction
None reported.

Pregnancy and lactation
No data available.

In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

E/S/C/O/P
MONOGRAPHS

Effects on ability to drive and use machines
Not relevant.

Undesirable effects
None reported.

Overdose
Not applicable.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antibacterial activity
The inhibition of *Mycobacterium tuberculosis* with various degrees of drug resistance was demonstrated by an ethanolic extract of dried flowers (not further specified) [Skvortsova 2015].

The effect of a methanolic extract (total phenolic content 160.17 mg/g) on lower respiratory tract pathogens was investigated. *Staphylococcus aureus* ATCC 25923 was more susceptible to the extract than *Streptococcus pneumoniae* ATCC49619 (MIC= 0.62 and 1.25 mg/mL respectively). The extract showed an MIC of 2.5 mg/mL against methicillin-resistent *S. aureus* and penicillin-resistent *S. pneumoniae*. The activity was higher against ampicillin-resistent *Moraxella catarrhalis* isolate (MIC=0.15 mg/mL) [Gradinaru 2014].

Antioxidant and radical-scavenging effects
Lyophilised aqueous extracts from two different samples (total polyphenol content: 10.6±0.6 g% and 17.6±0.7 g% respectively; total flavonoid content: 0.57±0.04 g% and 2.0±0.2 g% respectively) were investigated for their effect on microsomal lipid peroxidation in rat liver microsomes. NADPH+Fe^{3+}-induced lipid peroxidation in liver microsomes was dose-dependently decreased by the extracts to a significantly (P_1=0.003, P_2=0.005) greater extent than found for silibinin. The extracts also concentration-dependently stimulated NADPH cytochrome P450 reductase activity; although both extracts had a significantly (P_1= 0.017, P_2=0.018) greater effect than silibinin, the extract with a higher content of polyphenols and flavonoids demonstrated greater activity [Czinner 2001].

The antioxidant properties of two different lyophilised aqueous extracts (total flavonoid content: 0.57±0.06 g% (1) and 2.0±0.2 g% (2); total polyphenol content: 10.7±0.6 g% (1) and 17.6±0.7% (2)) were compared to silibinin using DPPH in a hydrogen-donating ability assay, and also measured by reducing power compared to ascorbic acid. Total scavenger capacity was detected with a chemiluminometric method, the H_2O_2/OH• luminol-microperoxidase system. Lyophilisate 2 proved to be more effective (IC_{50}=0.14±0.015 mg) at scavenging DPPH radicals compared to lyophilisate 1 (IC_{50}=0.36±0.015 mg) and silibinin standard dose (IC_{50}=0.65±0.08 mg). Lyophilisate 2 showed greater reducing power (1049.0 ± 2.86 ascorbic acid equivalents (ASE/mg)) compared with silibinin (447.7±5.16 ASE/mg) and lyophilisate 1 (379.7±4.21 ASE/mg). The total scavenging activity of lyophilisate 2 (IC_{90}=0.154µg) was much greater than silibinin (IC_{90}=194µg) 2 and lyophilisate 1 (IC_{90}=230µg) [Czinner 2000].

UV-protecting effects
The UVA/UVB protecting effects of an ethyl acetate fraction of an extract rich in chlorogenic acid (265.3±7.5 mg of gallic acid equivalent per g of extract) and flavonoids (84.0±3.2 mg of quercetin equivalent per g of extract) were studied. The fraction showed protective effects (PF-UVA $_{\text{in vitro}}$ =7.0 (±0.2) and UVA/UVB=1.1) [Jarzycka 2013].

Anti-inflammatory effects
The effect of the flavonoids narirutin, naringenin, astragalin and kaempferol on the proliferation of vascular smooth muscle A7r5 cells for 24 h at concentrations of 10, 50 and 100 µM was measured. Astragalin and kaempferol inhibited the proliferation of A7r5 cells (50 µM). Kaempferol (25 and 50 µM) inhibited the expression of CRP, VEGF and JNK2 and decreased NO synthesis (20 µM) [Mao 2017].

An antimutagenic activity of an extract (not further specified) at doses of 100 and 200 mg/kg was found in erythrocytes of white mice pre-treated with cyclophosphamide as a mutagen [Durnova 2015].

In vivo experiments
A single dose of a hydroethanolic extract (ethanol 70% V/V; not further specified) was tested for diuretic activity in male and female rats (50 mg/kg b.w. p.o.). Urine was collected at 4 and 24 hours after administration of the extract and tested for sodium, potassium and creatinine levels. The volume of urine was significantly ($p<0.001$) increased compared to control (water-alcohol load) after 4 and 24 hours. Sodium concentration was significantly increased after 4 hours ($p<0.001$) and 24 hours ($p<0.05$), compared to control. Potassium concentration was significantly ($p<0.05$) increased compared to control after both 4 and 24 hours. Creatinine levels were significantly greater than control after 4 hours ($p<0.05$) and 24 hours ($p<0.001$) [Kurkin 2015].

A methanolic extract (5:1) inhibited the increase in blood glucose in sucrose-loaded mice at 500 mg/kg. The extract also inhibited the enzymatic activity of dipeptidyl peptidase-IV (DPP-IV, IC_{50}=42.1 µg/ml), but not of intestinal α-glucosidase [Morikawa 2015].

The choleretic, diuretic, spasmolytic and hypotensive effects of an ethanolic extract (A; not further specified) and three different fractions thereof, obtained with diethyl ether (B) and ethyl acetate (C) as well as the aqueous fraction (D) were studied. The pure compounds 3-kaempferol glucoside, 5-naringenin glucoside and apigenin, as well as a decoction and an infusion, were also studied. In 171 male rats, a choleretic activity was found for the pure flavonoids and preparations A, B and C when administered i.v. or intraduodenally. The infusion and decoction were active only after i.v. administration. No diuretic effect was found in dogs and rats. The spasmolytic effect was tested on gallbladder from hamster and rabbits and on smooth muscle isolated from rats and rabbits. Only fraction D induced muscle contraction while all other preparations had no effect. In dogs, hypotensive effects of the preparations were seen after i.v. administration only [Szadowska 1962].

Clinical studies
No published clinical data currently available.

Pharmacokinetic properties
No data available.

Preclinical safety data
No data available.

Clinical safety data
No data available.

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

HYDRASTIS RHIZOMA 2013

Goldenseal rhizome

DEFINITION

Goldenseal rhizome consists of the whole or cut, dried rhizome and root of *Hydrastis canadensis* L. It contains not less than 2.5 per cent of hydrastine ($C_{21}H_{21}NO_6$; M_r 383.4) (dried drug) and not less than 3.0 per cent of berberine ($C_{20}H_{19}NO_5$; M_r 353.4) (dried drug).

The material complies with the monograph of the European Pharmacopoeia [Goldenseal].

CONSTITUENTS

Isoquinoline alkaloids (2.4 – 7%) [Blaschek 2007; Barnes 2007; Upton 2001; Galeffi 1997; Bradley 1992]:

- protoberberine alkaloids: berberine (2.5 – 4.5%), berberastine (2 – 3%), canadine (0.5 – 1%), corypalmine and isocorypalmine.
- phthalylisoquinoline alkaloids: hydrastine (1.5 – 4%), hydrastidine and isohydrastidine.
- benzylisoquinoline alkaloids: candaline and canadinic acid.

Quinic acid derivatives (up to 2.5%), mainly 5-O-(4′-[β-D-glucopyranosyl] trans-feruloyl)quinic acid [McNamara 2004] and methylated luteolin 7-methyl ethers [Hwang 2003].

CLINICAL PARTICULARS

Therapeutic indications

Digestive disorders such as dyspeptic complaints and gastritis; as an adjuvant in menorrhagia and dysmenorrhoea [Blaschek 2007; Barnes 2007; Mills 2013; Bradley 1992].

Efficacy in these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

0.5-1 g of the drug as a decoction three times daily; 0.3-1 mL of a liquid extract (1:1, ethanol 60%) three times daily [Bradley 1992; Barnes 2007]. Preparations accordingly.

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
Investigations in healthy volunteers with goldenseal rhizome revealed significant interactions with drugs that are metabolized by cytochrome P450 3A4/5 (e.g. midazolam) and 2D6 (e.g. debrisoquin) [Gurley 2005; Gurley 2008a; Gurley 2008b].

Pregnancy and lactation
The product should not be used during pregnancy or lactation [Blaschek 2007; Barnes 2007; Upton 2001; Mills 2013; Bradley 1992].

E/S/C/O/P
MONOGRAPHS

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
Although no case reports are available, exaggerated reflexes, depression, delirium, vomiting and cyanosis have been mentioned [Blaschek 2007; Barnes 2007].

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

The pharmacodynamics of the key constituents berberine and hydrastine have been studied thoroughly. The following pharmacological activities have been demonstrated [Simeon 1989; Mills 2013; Upton 2001]:

For berberine:
- antibacterial, antifungal, antiparasitic
- antidiarrhoeal, intestinal antisecretory
- antiarrhythmic, positive inotropic
- cytotoxic, antitumoral
- cholagogue, choleretic

For hydrastine:
- choleretic
- sedative
- antibacterial
- vasoconstrictive

In vitro experiments

Antimicrobial and antiviral activity
A 95% ethanolic extract of goldenseal rhizome exhibited antimicrobial activity against *Staphylococcus aureus, Klebsiella pneumoniae, Mycobacterium smegmatis* and *Candida albicans* with an MIC of 1 mg/mL [Gentry 1998].

A 70% ethanolic extract of goldenseal rhizome (standardized to 10 mg/mL berberine) showed antimicrobial activity against *Staphylococcus aureus* and *Streptococcus sanguis* with MICs of 0.12 mg/mL and 0.5 mg/mL (expressed as berberine) respectively. The bactericidal activity was evaluated in a contact test: the extract at 10 mg/mL was bactericidal within 4 to 30 min against the test strains compared to 0.5 - 4 min for hydrogen peroxide at 30 mg/mL [Scazzocchio 2001; Villinski 2003].

A 95% methanolic extract of goldenseal rhizome inhibited the growth of 15 strains of *Helicobacter pylori* with an MIC_{50} range of 12.5-50 µg/mL [Mahady 2003].

In a screening of herbal extracts for antibacterial activity against *H. pylori* and *Campylobacter jejuni* a goldenseal rhizome extract (ethanol 45%; DER 1:3) showed inhibition of both organisms [Cwikla 2010].

A methanolic (100%) extract of goldenseal rhizome showed antimicrobial activity against *Streptococcus mutans* and *Fusobacterium nucleatum* with MICs of 250 µg/mL and 62.5 µg/mL respectively. A bioguided fractionation of the extract led to the isolation of berberine (MIC: 125 µg/mL and 15.6 µg/mL, respectively) and 6-C-methylluteolin 7-methyl ether (MIC: 250 µg/mL and 375 µg/mL, respectively) as active compounds [Hwang 2003].

A 50% ethanolic extract of goldenseal rhizome completely inhibited influenza A growth in RAW 264.7 cells from a concentration of 2.5 µM of berberine (IC_{50} = 0.22 µM) compared to pure berberine (IC_{50} 0.01 µM) and amantadine (IC_{50} 27 µM) [Cecil 2011].

Smooth muscle relaxant activity
A 70% ethanolic extract of goldenseal rhizome dose-dependently inhibited the contractions induced by adrenaline on rabbit aorta strips (IC_{50} 0.88 µM, calculated as berberine). The activity of the isolated alkaloids berberine, canadine and canadaline was less pronounced (IC_{50} 2.6 – 5.2 µM) [Palmery 1996].

An extract of goldenseal rhizome providing berberine at 2.45 µM significantly ($p<0.01$) inhibited the contractions of rabbit prostate strips induced by noradrenaline or phenylephrine [Baldazzi 1998].

A 70% ethanolic extract of goldenseal rhizome induced relaxation in bladder detrusor muscle strips comparable to isoproterenol (88% of the isoproterenol-evoked response). Propranolol reduced this response by 69% suggesting that β-adrenergic stimulation was not the only mechanism [Bolle 1998].

A 70% ethanolic extract of goldenseal rhizome dose-dependently inhibited spontaneous contractions of uterine strips of non-pregnant rats (IC_{50} 10 µg/mL) and contractions induced by serotonin (IC_{50} 19.9 µg/mL), oxytocin (IC_{50} 10.5 µg/mL) and acetylcholine (IC_{50} 10 µg/mL). The extract also relaxed carbachol precontracted guinea-pig trachea (EC_{50} 1.6 µg/mL). The effect was partially antagonized by timolol, suggesting again that β-adrenergic stimulation was not the only mechanism [Cometa 1998].

In another study using the same guinea-pig trachea model the relaxant effect of a 70% ethanolic extract of goldenseal rhizome was confirmed (EC_{50} 1.5 µg/mL). The EC_{50} value of isolated alkaloids was also determined: hydrastine (72.8 µg/mL), berberine (34.2 µg/mL), canadine (11.9 µg/mL) and canadaline (2.4 µg/mL). Timolol antagonized the effect of canadine and canadaline but not that of berberine and hydrastine, while an adenosine receptor antagonist (xanthine amine congener) antagonized the effect of canadaline and hydrastine, but not of berberine and canadine. Extract concentrations from 0.01 to 0.1 µg/mL significantly ($p<0.01$) potentiated the relaxant effect of isoprenaline [Abdel-Haq 2000].

Antioxidant activity
A 70% ethanolic extract of goldenseal rhizome showed an antioxidant activity in the ABTS assay in a dilution of 1:1000. The effect was comparable to 40 µM trolox [Pereira da Silva 2000].

Immunomodulating activity
A 50% ethanolic extract of goldenseal rhizome reduced the production of TNF-α and the interleukins 6, 10 and 12 in lipopolysaccharide-stimulated macrophages in a dose-dependant manner [Clement-Kruzel 2008].

A 50% ethanolic extract of goldenseal rhizome significantly ($p<0.05$) inhibited the production of TNF-α and PGE_2 in influenza A infected RAW 264.7 cells at a concentration corresponding to 25 µM of berberine [Cecil 2011].

Influence on cytochrome P450
Serial dilutions (from 100% to 1.56%) of 21 commercial ethanolic herbal extracts and tinctures were analyzed for their ability to inhibit CYP3A4 via a fluorometric microtiter plate assay. An ethanolic extract of goldenseal rhizome gave the strongest inhibition with a calculated IC_{50} of 0.03% [Budzinski

2000]. In the same assay an aqueous extract of two commercial products (product 1 containing 450 mg goldenseal rhizome powder per capsule; product 2 containing 250 mg extract, standardised to 10% alkaloids, and 65 mg rhizome powder per capsule) gave an IC_{50} of 3.03 and 3.23 mg/mL, respectively [Budzinski 2008].

A commercial extract of goldenseal rhizome (containing approximately 17 mM berberine and hydrastine) inhibited CYP2C9 (diclofenac 4-hydroxylation), CYP2D6 (bufuralol 1'-hydroxylation) and CYP3A4 (testosterone 6β-hydroxylation) in human hepatic microsomes. The inhibition of CYP3A4 was non-competitive with an apparent Ki (= dissociation constant of inhibitor) of 0.1% extract [Chatterjee 2003].

An aqueous and ethanolic extract of goldenseal rhizome (equivalent to 20 µM berberine plus hydrastine) exerted more than 50% inhibition of the activity of CYP2C8 (paclitaxel 6α-hydroxylation), CYP2D6 (dextromethorphan O-demethylation) and CYP3A4 (midazolam 1-hydroxylation and testosterone 6β-hydroxylation) in human hepatic microsomes. CYP2E1 activity (p-nitrophenol hydroxylation) was inhibited by 20 µM berberine, but was not affected by either the extracts or hydrastine (20 µM). The extracts, as well as berberine and hydrastine, stimulated human P-glycoprotein (Pgp) ATPase activity at about 50% of the activity of verapamil (20 µM) [Etheridge 2007]. Goldenseal rhizome tea (containing 0.2% hydrastine and 1.0% berberine) had a greater stimulatory effect on Pgp ATPase than verapamil (20 µM) [Budzinski 2008].

In contrast to the previous study, CYP2E1 activity (p-nitrophenol hydroxylation) was inhibited by berberine (4 µM, 11% decrease), hydrastine (4 µM, 64% decrease) and by a 50% ethanolic extract of goldenseal rhizome (corresponding to 1.7 µM berberine and 1.2 µM hydrastine, 55% decrease). Inhibition of CYP2E1 appeared to be competitive with a Ki of 18 µM, 2.8 µM and 0.1%, respectively [Raner 2007].

In vivo experiments

Antidiabetic activity
Goldenseal rhizome, incorporated into the diet at 6.25% for 9 days, significantly ($p<0.05$) reduced hyperphagia and polydipsia in streptozotocin-diabetic mice [Swanston-Flat 1989].

Immunomodulating activity
Goldenseal rhizome extract (not further specified) was administered to rats for 6 weeks (1 g/l of drinking water). At days 0, 14 and 28 the antigen KLH (keyhole limpet haemocyanin) was injected. The treated group showed a significant ($p<0.05$) increase in the primary IgM response during the first 2 weeks, whereas the IgG levels in treated and control rats were identical [Rehman 1999].

Lipid-lowering activity
Berberine (1.8 mg/animal) or goldenseal rhizome extract (125 µL/animal, equivalent to 0.9 mg berberine) was administered intraperitoneally to hyperlipidaemic hamsters once per day for 24 days. Goldenseal significantly ($p<0.001$) reduced total plasma cholesterol by 31%, LDL-cholesterol by 25% and triglycerides by 33% compared to control. The activity of berberine was almost identical [Abidi 2006].

Anti-carcinogenic activity
Oral administration of a 90% ethanolic extract (not further specified; 0.06 mL three times daily for 4 months) to mice chronically fed p-dimethylaminoazobenzene (0.06% in the diet) and phenobarbital (0.05% in the diet) markedly reduced the liver tumour incidence and the elevation of serum phosphatases and transferases. This was confirmed histopathologically by a decrease of necrosis, vascular congestion, fibrosis and damage to intracellular organelles in livers of the treated mice [Karmakar 2010].

Pharmacological studies in humans

In a randomized, cross-over study 12 healthy volunteers received a goldenseal rhizome extract (900 mg, 3 times daily) for 28 days. Probe drug cocktails (midazolam and caffeine, chlorzoxazone and debrisoquin) were administered before and at the end of supplementation. Determination of cytochrome P450 activity 1A2, 2D6, 2E1 and 3A4/5 revealed a significant ($p<0.05$) inhibition (approximately 40%) of CYP2D6 and CYP3A4/5 [Gurley 2005].

In a cross-over study, the pharmacokinetics of indinavir were characterized in 10 healthy volunteers before and after treatment with goldenseal rhizome (1140 mg, twice daily for 28 days). No significant differences in peak concentration or oral clearance were observed, suggesting that interactions with drugs metabolized by CYP3A4 are unlikely [Sandhu 2003]. However indinavir is less suitable as a probe for assessing changes in CYP3A4/5 activity due to its high oral bioavailability [Gurley 2005].

In a randomised, cross-over study the effect of treatment with a standardized goldenseal rhizome extract (1070 mg, containing 24.1 mg isoquinoline alkaloids, 3 times daily for 14 days) on digoxin pharmacokinetics was determined in 20 healthy volunteers. No clinically relevant effects on digoxin pharmacokinetics were observed. When compared to rifampin (= rifampicin) and clarithromycin, goldenseal rhizome does not seem to be a potent modulator of P-glycoprotein [Gurley 2007].

Sixteen healthy volunteers received a goldenseal rhizome extract, corresponding to 132 mg hydrastine and 77 mg berberine per day, for 14 days. Midazolam (8 mg, per os) was admistered 1 day before and on the last day of treatment. Comparison of pre- and post-treatment midazolam pharmacokinetic parameters revealed significant inhibition of CYP3A: AUC(0-∞): 108 vs. 175 ng*h/mL ($p<0.001$); apparent oral clearance normalised to body weight: 1.3 vs. 0.8 l/h/kg ($p<0.001$); $T_{1/2}$ elimination: 2.0 vs. 3.2 h ($p<0.001$) and C_{max}: 51 vs. 71 ng/mL ($p<0.05$)[Gurley 2008b]. In a comparable study, debrisoquin (5 mg, orally) was administered before and at the end of goldenseal treatment (same product, same dose). Comparison of pre- and post-treatment urinary recovery ratios of debrisoquin revealed significant ($p<0.05$) inhibition of CYP2D6: 0.71 vs. 0.37 [Gurley 2008a].

Clinical studies
No data available.

Pharmacokinetic properties
No data available for goldenseal rhizome.

Pharmacokinetics in animals
After oral administration of berberine sulphate to rats at doses of up to 1 g/kg body weight only very small amounts of berberine were detected in a few tissues. As anticipated for a quaternary alkaloid, examination of the intestines revealed that berberine was neither well absorbed nor destroyed [De Smet 1992].

After oral administration of berberine to rats at a lower dose of 40 mg/kg, berberine, four metabolites and their glucuronide conjugates were found in plasma, bile and urine. Berberine reached its peak plasma concentration (10 µg/l) after 2 hours and was eliminated within 12 hours (AUC(0-∞): 37 ng*h/mL). However, the peak plasma concentration and AUC(0-∞) values

of the metabolites were much higher: e.g. AUC(0-∞) of 1880 ng*h/mL for the main metabolite berberrubine. About 34% of the oral dose was absorbed from the gastrointestinal tract within 1 hour. [Zuo 2006].

Intravenous administration of berberine to rats at 10 mg/kg resulted in $T_{1/2}$ elimination of 0.3 h and AUC0-∞ of 265 µg*min/mL (plasma)/1470 µg*min/mL (bile). Only a small amount of berberine was detected in urine. Berberine was rapidly transported from blood into liver and bile (via P-glycoprotein) and metabolised with phase I demethylation (CYP450) and phase II glucuronidation [Tsai 2004].

The cumulative urinary and biliary excretion of berberine after i.v. administration of 2 mg/kg to rabbits was 4.9% and 0.5% of the administered dose respectively (AUC: 0.84 µg*h/mL) [Chen 1995].

Berberine was given orally to dogs in a single dose of 280 mg/kg body weight and resulted in a C_{max} of 15.5 µg/mL, T_{max} of 3.7 h and AUC0-∞ of 777 µg*h/mL. At this high dose vomiting occurred within 1 h [Upton 2001].

Pharmacokinetics in humans
In an uncontrolled study, 56 patients with congestive heart failure received 1.2 g berberine per day orally for 2 weeks. Peak plasma levels were reached in about 2.4 h ranging from 0.07 to 0.19 mg/l [Zeng 1999].

After oral administration of berberine to 5 volunteers at a dose of 900 mg/day for 3 days, 3 sulphate-conjugated metabolites were isolated and identified in the urine [Pan 2002].

An oral dose of 300 mg berberine was given 3 times daily for 2 days to 12 healthy volunteers. In their urine 7 metabolites could be identified: phase I metabolites formed by cleavage of the dioxymethylene ring or by demethylation, most of them were conjugated with glucuronic or sulphuric acid (phase II metabolites) [Qiu 2008].

Preclinical safety data

Acute and repeated dose toxicity
The oral LD_{50} of an extract of goldenseal rhizome in mice was 1620 mg/kg body weight [Blaschek 2007; Mills 2013].

The oral LD_{50} of berberine in mice was 329 mg/kg body weight. Oral doses of up to 100 mg/kg of berberine sulphate have been well tolerated in animal studies without permanent effects. However, prolonged administration caused organ damage and death after 8 to 10 days [De Smet 1992; Mills 2013].

The LD_{50} values of hydrastine in rats were 1000 mg/kg body weight (oral), 1270 mg/kg (subcutaneous) and 104 mg/kg (intraperitoneal) [Blaschek 2007].

Chronic toxicity
In a two-year toxicity study goldenseal rhizome powder (3.9% berberine, 2.8 hydrastine and 0.2% canadine) was administered to male and female rats and mice at up to 25% of the feed. The primary finding was an increase in liver tumours in rats and mice at the highest dose (25%) [Dunnick 2011].

Reproductive toxicity
In a preliminary experiment, non-pregnant, female rats were dosed by oral gavage with a liquid extract of goldenseal rhizome (45% ethanol; 333 mg/mL goldenseal; standardized to 9.3 mg/mL berberine and 8.4 mg/mL hydrastine) at incremental doses for 8 days. The maximum dose of 1.86 g/kg body weight/day was non-maternotoxic. This dose was administered daily to female rats on either gestation days (GD) 1-8 or GD 8-15. Controls received an equivalent dose of ethanol. On GD 20, foetuses were weighed and examined for signs of external, internal, or skeletal malformations: differences between the treated and control group could not be demonstrated. When rat embryos were explanted and cultured with the extract at concentrations from 0.5 to 6 µL/mL, growth retardation and embryotoxicity were demonstrated in a dose-dependent manner. A possible poor absorption of orally administered goldenseal could explain the discrepancy between the in vivo and in vitro results [Yao 2005].

Berberine was administered in the feed and by gavage to pregnant rats on GD 6-20 and to pregnant mice on GD 6-17. A mortality of 33% of the mice exposed to 792 mg/kg/day berberine by gavage was observed. The following NOAEL (no observed adverse effect level) and LOAEL (lowest observed adverse effect level) values were determined [Jahnke 2006]:

	LOAEL (mg/kg/day)	NOAEL (mg/kg/day)
Rat maternal toxicity	420	223
Rat developmental toxicity	>792	792
Mouse maternal toxicity	666	450
Mouse developmental toxicity	792	666

Clinical safety data

In an 11 year old girl with diabetic ketoacidosis, the degree of hypernatraemia and hyperosmolality was enhanced after intake of 500 mg goldenseal (not further specified) 2 to 3 times daily for 2 weeks, but a causal relationship could not be demonstrated [Bhowmick 2007].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

Plant illustrated on the cover: *Hypericum perforatum*

FOREWORD

It is a great pleasure for me, on behalf of my colleagues in ESCOP, to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

TABLE OF CONTENTS: PHARMACOLOGICAL PROPERTIES

HYPERICI HERBA

2018

St. John's Wort

DEFINITION

St. John's wort consists of the whole or cut, dried flowering tops of *Hypericum perforatum* L., harvested during flowering time. It contains not less than 0.08 per cent of total hypericins, expressed as hypericin ($C_{30}H_{16}O_8$; M_r 504.4) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia 2013 [St. John's wort].

CONSTITUENTS

The characteristic constituents are naphthodianthrones and phloroglucinols. Naphthodianthrones (0.05-0.3%), consisting mainly of hypericin and pseudohypericin, accumulate primarily in the flowers and buds [Nahrstedt 1997]. Other naphthodianthrones are the biosynthetic precursors protohypericin and protopseudohypericin (which are transformed into hypericin and pseudohypericin respectively on exposure to light), and a small amount of cyclopseudohypericin [Häberlein 1992; Krämer 1992; Schütt 1994].

The principal phloroglucinols are hyperforin (2-4.5%) and adhyperforin (0.2-1.8%) [Bergonzi 2001; Greeson 2001; Maisenbacher 1992]. Both compounds have limited stability [Bilia 2001; Fuzzati 2001; Orth 1999a; Orth 1999b; Trifunovic 1998] and their oxidated derivatives are also present [Bergonzi 2001].

Quercetin glycosides (2-4%), including hyperoside, quercitrin, isoquercitrin and rutin are the main flavonoids [Hölzl 1987; Nahrstedt 1997; Tekel'ová 2000]; a small amount of free quercetin [Tekel'ová 2000]. Biflavonoids such as I3,II8-biapigenin (0.1-0.5%) and I3',II8-biapigenin (amentoflavone, 0.01-0.05%) occur exclusively in the flowers [Berghöfer 1987; Nahrstedt 1997; Tekel'ová 2000].

Other constituents include phenylpropanoids, such as chlorogenic acid and other caffeoylquinic and *p*-coumaroylquinic esters [Jürgenliemk 2002; Nahrstedt 1997]; polymeric and oligomeric proanthocyanidins [Brantner 1994; Nahrstedt 1997] including procyanidins A2, B1, B2, B3, B5, B7 and C1 [Melzer 1991; Ploss 2001], together with catechin and epicatechin monomers [Nahrstedt 1997; Ploss 2001]; trace amounts of xanthones such as 1,3,6,7-tetrahydroxyxanthone (0.0004% in the leaves and stems) [Nahrstedt 1997; Sparenberg 1993]; and essential oil (0.1-0.25%), containing mainly higher *n*-alkanes and monoterpenes [Nahrstedt 1997].

CLINICAL PARTICULARS

Therapeutic indications

Preparations based on hydroalcoholic extracts (50-68% ethanol, 80% ethanol or 80% methanol)

Preparations based on dry extract, extraction solvent **ethanol (50-68% V/V)**:

Episodes of mild depressive disorders [Häring 1996; Harrer 1999; Hoffmann 1979; Hübner 1994; Kalb 2001; Kugler 1990; Laakmann 1998; Lenoir 1999; Philipp 1999; Quandt 1993; Schlich 1987; Sommer 1994; Witte 1995; Woelk 2000a].

Preparations based on dry extract, extraction solvent **methanol (80% V/V)**, and dry extract, extraction **solvent ethanol (80% V/V or 50% V/V)**:

Mild to moderate depressive episodes in accordance with ICD-10 categories F32.0, F32.1, F33.0 and F33.1 (see the boxes below) [Anghelescu 2006; Bjerkenstedt 2005; Brenner 2000; Fava 2005; Gastpar 2005; Gastpar 2006; Halama 1991; Hänsgen 1994; Häring 1996; Harrer 1994; Harrer 1991; Holsboer-Trachsler 1999; Hübner 2000; Hübner 1994; Kaehler 1999; Kasper 2006; Kasper

E/S/C/O/P MONOGRAPHS

2007a; Kasper 2007b; Kasper 2008; Lecrubier 2002; Lehrl 1993; Mannel 2010; Meier 1997; Montgomery 2000; Sarris 2012; Schmidt 1989; Schrader 2000; Schrader 1998; Shelton 2001; Singer 2011; Sommer 1994; Szegedi 2005; Uebelhack 2004; Vorbach 1997; Vorbach 1994; Wheatley 1997; Woelk 1994].

Other Preparations

Comminuted and powdered herbal substance as well as the following preparations:

- Dry extract (DER 4-7:1), extraction solvent ethanol 38% (m/m)
- Liquid extract (DER 1:13), extraction solvent maize oil or other suitable vegetable oil
- Tincture (DER 1:10), extraction solvent ethanol 45-50% (V/V)
- Tincture (DER 1:5), extraction solvent ethanol 50% (V/V)
- Liquid extract (DER 1:2), extraction solvent ethanol 50% (V/V)
- Liquid extract (DER 1:5-7), extraction solvent ethanol 50% (V/V)
- Expressed juice from the fresh herb:

Relief of temporary mental exhaustion [Behnke 2002; Engesser 1996; Harrer 1991; Hoffmann 1979; Kugler 1990; Lenoir 1999; Quandt 1993; Rapaport 2011; Schlich 1987; Schmidt 1989; Warnecke 1986; Werth 1989].

Liquid extract (DER 1:4-20), extraction solvent vegetable oil; tincture (DER 1:10), extraction solvent ethanol 45-50% (V/V); and tincture (DER 1:5), extraction solvent ethanol 50% (V/V):

Symptomatic treatment of minor inflammations of the skin (such as sunburn) and as an aid in healing of minor wounds [Gerlach 2008; Samadi 2010; WHO 2002; Wichtl 2004].

Comminuted herbal substance:

Symptomatic relief of mild gastrointestinal discomfort: [Grünwald 2004; Hänsel 1993; Wichtl 2004].

Posology and method of administration

Dosage

Preparations based on hydroalcoholic extracts (50-68% ethanol, 80% ethanol or 80% methanol)

Adults and children from 12 years:

450-1050 mg daily of hydroalcoholic dry extracts with DERs of 2.5-5:1, 4-7:1 or 5-7:1 [Anghelescu 2006; Bjerkenstedt 2005; Brenner 2000; Fava 2005; Gastpar 2005; Gastpar 2006; Halama 1991; Hänsgen 1994; Häring 1996; Harrer 1994; Harrer 1999; Holsboer-Trachsler 1999; Hübner 2000; Hübner 1994; Kaehler 1999; Kalb 2001; Kasper 2006; Kasper 2008; Laakmann 1998; Lecrubier 2002; Lehrl 1993; Mannel 2010; Martinez 1994; Meier 1997; Philipp 1999; Rapaport 2011; Rychlik 2001; Schrader 2000; Schrader 1998; Shelton 2001; Sommer 1994; Szegedi 2005; Uebelhack 2004; Vorbach 1994; Wheatley 1997; Woelk 2000a; Woelk 1994].

1200 – 1800 mg daily of hydroalcoholic dry extracts with DERs of 2.5-5:1, 4-7:1 or 5-7:1 [Anghelescu 2006; Davidson 2002; Kasper 2006; Rychlik 2001; Shelton 2001; Szegedi 2005; Vorbach 1997].

Children from 6 to 12 years under medical supervision only.

Other Preparations

Comminuted and powdered herbal substance as well as the following preparations:

- Dry extract (DER 4-7:1), extraction solvent ethanol 38% (m/m)
- Liquid extract (DER 1:13), extraction solvent maize oil or other suitable vegetable oil
- Tincture (DER 1:10), extraction solvent ethanol 45-50% (V/V)
- Tincture (DER 1:5), extraction solvent ethanol 50% (V/V)

Classification of severity of depression based on ICD-10 criteria [WHO 2010]

Mild depressive episode [F32.0/F33.0]	Mild first manifestation or mild recurrence of at least two target signs and at least two associated symptoms
Moderate depressive episode: [F32.1/F33.1]	Two or three target signs and at least three or four associated symptoms (first manifestation or recurrent episode)
Severe depressive episode: [F32.2/F33.2/F32.3/F33.3]	All three target signs and at least four associated symptoms, some particularly pronounced (first manifestation or recurrent, without or with psychotic symptoms)

Diagnostic features of depressive disorders according to ICD-10 Chapter V Primary Care Version [WHO 2010]

Target signs	***Associated symptoms***
Low or sad mood	Disturbed sleep
Loss of interest or pleasure	Feelings of guilt and unworthiness
Fatigue or loss of energy	Reduced self-esteem and self-confidence
	Poor concentration
	Disturbed appetite
	Decreased libido
	Suicidal thoughts or acts
	Agitation or slowing of movement or speech
	Weight loss

Symptoms of anxiety or nervousness are also frequently present

- Liquid extract (DER 1:2), extraction solvent ethanol 50% (V/V)
- Liquid extract (DER 1:5-7), extraction solvent ethanol 50% (V/V)
- Expressed juice from the fresh herb:

Single oral dose:
60 – 200 mg extract, liquid preparation 1-20 mL, comminuted herbal substance (tea) 1.5-2 g, or powdered herbal substance 300-500 mg.

Daily oral dose:
180-360 mg extract, liquid preparation 6-30 mL, comminuted herbal substance (tea) 3-6 g, or powdered herbal substance 900-1000 mg.

[Harrer 1991; Hoffmann 1979; Kugler 1990; Quandt 1993; Schlich 1987; Schmidt 1989; Warnecke 1986; Werth 1989; Engesser 1996].

Undiluted preparations for cutaneous administration: liquid extract (DER 1:4-20), extraction solvent vegetable oil; tincture (DER 1:10), extraction solvent ethanol 45-50% (V/V) or tincture (DER 1:5), extraction solvent ethanol 50% (V/V) [Gerlach 2008; Samadi 2010; WHO 2002; Wichtl 2004].

Comminuted herbal substance for tea preparation: single dose 2 g and daily dose 4 g [Grünwald 2004; Hänsel 1993; Wichtl 2004]

Elderly: dose as for adults.

Method of administration
For oral administration and topical application.

Duration of administration

- Mild to moderate depressive episodes: no restriction. If symptoms persist for more than 6 weeks or worsen, medical advice should be sought.

- Relief of temporary mental exhaustion: if symptoms persist for more than 1 week or worsen, medical advice should be sought.

- Symptomatic treatment of minor inflammations of the skin (such as sunburn), as an aid in healing of minor wounds and symptomatic relief of mild gastrointestinal discomfort: if symptoms persist for more than 2 weeks or worsen, medical advice should be sought.

Contra-indications
Known hypersensitivity to the active substance.

Oral administration of preparations with a daily dose of more than 1000 mg drug equivalent or more than 1 mg hyperforin:
Concomitant use with certain immunosuppressants (ciclosporin, tacrolimus or sirolimus for systemic use), certain anti-retroviral HIV-drugs from the group of non-nucleoside reverse transcriptase inhibitors (e.g. nevirapine), protease inhibitors (e.g. indinavir, amprenavir), certain cytostatics (e.g. imatinib, irinotecan), and oral anti-coagulants of the coumarin type (e.g. warfarin). See also section on Interactions.

Special warnings and special precautions for use
Very rarely, and especially in fair-skinned persons, unwanted reactions of the skin (sunburn-like redness) may occur following ingestion of St. John's wort preparations and subsequent exposure to sun light. Intense UV-exposure should be avoided during treatment.

Oral administration of preparations with a daily dose of more than 1000 mg drug equivalent or more than 1 mg hyperforin:
Caution is indicated at the beginning and end of treatment with concomitant medications, as well as when making dosage changes of St. John's wort products.

Treatment with St. John's wort extract should be assessed with respect to interactions with co-medication at least 5 days before elective surgery, and again upon discharge from the hospital.

Interaction with other medication and other forms of interaction

Oral administration of preparations with a daily dose of more than 1000 mg drug equivalent or more than 1 mg hyperforin:
Administration of St. John´s wort extracts and some of its components can lead to an induction of several enzymes of the cytochrome P450 enzyme family (CYP3A, CYP2B6, CYP2C9 and CYP2C19), and the P-glycoprotein drug efflux transporter. For this reason, interactions can occur with drugs including amitryptiline, fexofenadine, benzodiazepines, methadone, simvastatin, finasteride, digoxin. The concomitant use of cyclosporine, tacrolimus for systemic use, amprenavir, indinavir and other protease inhibitors, irinotecan and anticoagulants (such as warfarin or phenprocoumon) is contraindicated. Women using oral hormonal contraceptives should be informed about possible mid-cycle bleeding as a result of interactions, and counselled on the use of additional contraceptive measures due to a possible reduction in contraceptive efficacy [Johne 1999, 2002; Sugimoto 2001; Gurley 2002; Dresser 2003; Eich-Hochli 2003; Mai 2004; Müller 2004; Murphy 2005; Lundahl 2009].

Several cases of serotonergic effects following concomitant use of St. John's wort preparations with certain antidepressants have been reported [Gordon 1998; Lantz 1999; Prost 2000; Dannawi 2002; Mannel 2004; Bonetto 2007]. The attribution of these cases to St. John's wort remains unclear.

Patients taking other medicines on prescription should consult a physician or pharmacist before taking St. John's wort.

Pregnancy and lactation
Studies generally do not show an impact of St. John's wort on pregnancy and lactation, although some animal studies showed equivocal results [Borges 2005; Dugoua 2006]. Several of these studies offer exposure data in humans [Demling 2004; Klier 2006; Lee 2003; Moretti 2009].
In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
Clinical studies indicate no negative influence on general performance or the ability to drive [Friede 1998; Herberg 1994; Schmidt 1991; Schmidt 1993].

Undesirable effects
At therapeutic dose levels (up to the equivalent of 6 g of drug), occasional mild gastrointestinal disturbances, nausea, restlessness, fatigue, headache, insomnia or allergic reactions have been reported.

Onset of mania and hypomania were reported in several patients with latent bipolar disorders [Fahmi 2002; Moses 2000; Nierenberg 1999].

Phototoxicity
Very rarely, and especially in fair-skinned people, reactions of the skin (sunburn-like redness) may occur after ingestion of St. John's wort preparations and subsequent exposure to sun light. Intense UV-exposure should be avoided during treatment [He 2004; Schempp 2003b].

Overdose
A 16-year old girl experienced seizures and confusion after ingestion of up to 4.5 g of an unspecified St. John's wort extract per day in the preceding 2 weeks and an additional 15 g before admission to the hospital [Karalapillai 2007]. On day 6 EEG was normalised and the patient discharged.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Effects on enzyme activity
A potent irreversible inhibition of monoamine oxidase type A and B (MAO-A and MAO-B) was found for hypericin with IC_{50} values of 6.8×10^{-4} M and 4.2×10^{-4} M respectively [Suzuki 1984]. As other studies did not confirm the MAO inhibitory effects of hypericin [Cott 1997; Demisch 1989; Sparenberg 1993; Thiede 1994], the MAO inhibition was explained as being due to a purity of only 80% of the tested compound with a possible 20% flavonoid content, for which MAO inhibition has been confirmed.

An extract (not further specified) as well as flavone, xanthone and kaempferol (IC_{50} of 1 to 3 µM) led to >90% inhibition of MAO-A [Demisch 1989].

Hyperforin (35 µmol/L) showed a 30.3% inhibition of MAO-A. A significant inhibition of MAO-A activity (66 – 96.2%), and to a lesser extent MAO-B activity (2.2 – 29.9%), was demonstrated for quercetin, quercitrin, luteolin and kaempferol at concentrations of 39 – 65 µmol/L [Sparenberg 1993].

Inhibition of MAO-A in rat brain homogenates was only shown at non-physiological concentrations of 1-10 mM of a methanolic (80% V/V) extract or a flavonoid-rich fraction thereof. Hypericin did not inhibit MAO-A. Additional *ex vivo* experiments did not show a relevant inhibition of MAO-A or MAO-B after i.p. administration of 100 mg/kg b.w. of 1,3-dihydroxyxanthone, quercitrin or the extract [Bladt 1994].

An undefined extract of fresh flowers and buds (containing 0.1% hypericin), at a concentration of 5 µg/mL, inhibited MAO-A by 93% and MAO-B by 49% [Cott 1997].

A weak inhibitory effect (IC_{50} = 120 and 370 µg/mL for MAO-A and MAO-B respectively) was obtained with a methanolic (80% V/V) extract containing 0.3% hypericin and 1.5% hyperforin [Müller 1997]. A hyperforin-enriched (38%) CO2 extract (>500 µg/mL) demonstrated no inhibition [Müller 1998].

Hyperforin at doses of up to 50 µg/mL did not inhibit MAO-A or MAO-B activities [Chatterjee 1998a].

On fractionation of an extract, an inhibition of catechu-*O*-methyl-transferase (COMT) was found for the hydrophilic fractions containing mainly flavonoids, as well as hypericins and xanthones. Hypericin did not inhibit COMT from pork liver at concentrations up to 1 mM (500 mg/L) [Thiede 1994].

Several studies have shown an inhibition of dopamine-β-hydroxylase by ethanolic extracts, hypericin and pseudohypericin [Kleber 1999].

Effects on receptor binding and regulation
Depression has been attributed to reduced availability of serotonin (5-HT), norepinephrine or dopamine, disturbances of the opioid receptor family, the GABA system, modulation of oestrogen, *N*-methyl-D-aspartate (NMDA) and glutamate receptor binding and the corticosteroidal system in the CNS. Consequently, antidepressants increase the levels of neurotransmitters, e.g. by reuptake inhibition or by inhibiting the degradation. NMDA receptor-mediated processes or binding to opioid receptors have also been considered to be involved in the mechanism of action of conventional antidepressants.

Adrenergic receptors
Methanolic extracts, hypericin and kaempferol (at 100 µg/mL) showed either no or only weak inhibition of the adrenergic α_1, α_2 and β_1-receptors [Müller 1996; Raffa 1998; Rolli 1995].

Hypericin potently inhibited binding to rat β_1 and β_2 receptors, whereas pseudohypericin had no effect on either receptor. Rutin and miquelianin showed significant binding inhibition at human α_{2C} adrenergic receptors (52.81% and 59.60% respectively) [Butterweck 2002b].

Cholinergic receptors
Hypericin at 1 µM displayed weak affinity (12%) to rat cortex nicotinic acetylcholine (Ach) receptors, and moderate affinity to muscarinic Ach receptors (49%) [Raffa 1998].

At human muscarinic Ach receptors M_1-M_5, hypericin (10 µM) was a weak inhibitor of M_2 receptor binding. Inhibition of binding to human muscarinic receptor subtypes was observed for miquelianin (M_2: 53.75%; M_5: 55.20%) and rutin (M_5: 53.82%). Affinity of rutin to M_5 receptors was K_i = 35.13 ± 13 nM (reference: pirenzepine, K_i = 20.59 ± 2.4 nM) [Butterweck 2002b].

Corticosteroid receptors
Corticotropin-releasing hormone (CRH) is a family of neuro-humoral factors which act on receptors including CRH_1. The corticosteroidal system seems to be particularly important in the pathogenesis of depression by changes in the regulation of the hypothalamic-pituitary-adrenal axis. Elevated levels of CRH have been found in the cerebrospinal fluid of depressed patients [Arborelius 1999], and antidepressant drugs are considered to normalise CRH hypersecretion [Stout 2002].

Bisanthraquinone glycosides isolated from an ethanolic (50%) extract inhibited binding of [^{125}I]-sauvagine to CRH_1-receptors with IC_{50} values of 1 to 4 µM. The IC_{50} values of hyperforin and hypericin were 10 and 6 µM [Wirz 2000].

A methanolic extract (0.2% hypericin and 5% hyperforin) weakly inhibited [^{125}I]-astressin binding to the human CRH_1 receptor with an IC_{50} of 50 µg/mL whereas hypericin (IC_{50} approximately 300 nM) and pseudohypericin (IC_{50} of 2 µM) were more active. Hyperforin did not show any inhibition up to 10 µM [Simmen 2001].

The effect of hypericin, pseudohypericin and hyperforin on corticotropin-releasing factor (CRF)-stimulated cAMP formation was studied in recombinant Chinese hamster ovary cells. Only pseudohypericin selectively antagonised CRF (K_B 0.76 µM) [Simmen 2003].

Dopamine (DA) receptors and DA transporters
Hypericin and pseudohypericin (10 µM) markedly inhibited binding to rat D_3- and D_4- receptors (approximately 70-80% inhibition), with pseudohypericin being more potent on D_4-receptors. Inhibition by hyperforin (10 µM) was 57% for the binding to D_1- and 63% to D_5-receptors. Amentoflavone (10 µM) showed a complete inhibition of binding to the D_3-receptor and a 70% inhibition at the DA transporter [Butterweck 2002b].

Weak interaction with the rat DA transporter system was shown for a methanolic extract (IC_{50} 24.5 µg/mL) and a CO_2 extract (IC_{50} of 12.9 µg/mL) [Gobbi 2001].

GABA receptors
An ethanolic extract inhibited binding to human $GABA_A$-receptors with an IC_{50} value of 1 to 3 µg/mL [Simmen 1999; Simmen 2001]. A hydromethanolic extract (4.5% hyperforin, 0.5% hypericin and 0.4% biapigenin) showed an inhibition of binding to $GABA_A$ and $GABA_B$ receptors with IC_{50} values of 5.5 and 8.0 µg/mL respectively [Gobbi 2001; Gobbi 1999].

A hydromethanolic (80%) extract inhibited radioligand binding of muscimol to the $GABA_A$-receptor with an IC_{50} of 1.6 ± 0.5 µg/mL [Wonnemann 1997].

A flower extract, obtained by extraction with methanol followed by acetone, inhibited binding of flumazenil to benzodiazepine receptors in rat brain with an IC_{50} of 6.8 µg/mL. Leaf extracts up to 200 µg/mL showed 25% inhibition of flumazenil binding. Of the single constituents tested, amentoflavone had an IC_{50} of 14.9 nM, whereas hypericin, flavones and glycosylated flavonoids did not inhibit binding [Baureithel 1997]. Amentoflavone binding activity at the benzodiazepine receptor with an IC_{50} of 6 nM was comparable to the affinity of diazepam [Nielsen 1988].

Various undefined extracts were investigated for their effect on neurotransmitter re-uptake. Dopamine re-uptake was studied in synaptosomes from male Wistar rats, all other uptake mechanisms (5-HT, norepinephrine (NE), GABA and L-glutamates) in those from female NMRI mice. Adhyperforin, like hyperforin, showed a strong inhibition in all systems. Hyperforin-free preparations were able to inhibit the uptake in a weak to moderate manner. Moreover, a weak to moderate inhibition was found for a fraction containing oligomeric procyanidins [Wonnemann 2001].

Amentoflavone (10 µM) inhibited binding to rat GABA receptors by 98%. Quercitrin, isoquercitrin, hyperoside and miquelianin exhibited only a weak effect. The affinity of amentoflavone to the rat benzodiazepine receptor was K_i = 6.17 ± 1.2 nM (reference: diazepam, K_i = 10.6 ± 2.2 nM) [Butterweck 2002b].

Examination of the binding sites of amentoflavone suggested a complex mechanism of interaction at the $GABA_A$ receptor. Amentoflavone appeared to act as an antagonist at the classical benzodiazepine site, whereas the functional effects at $GABA_A$ receptors were most likely mediated by mechanisms distinct from the benzodiazepine and lorecazole binding sites [Hansen 2005].

In a screening of an ethanolic extract, binding of radiolabelled ligands was strongly inhibited at the $GABA_A$ receptor (IC_{50} 1 µg/mL) [Simmen 1999].

A hydromethanolic extract demonstrated reduced expression of serotonin receptors in a neuroblastoma cell line model [Müller 1993].

NMDA and glutamate receptors
Binding of the selective ligand Ro 63-6599 to the human metabotropic glutamate receptor 2 (mGlu2) was not inhibited by an ethanolic (50%) extract or a methanolic/acetonic extract containing 0.2% hypericin and 5% hyperforin [Simmen 2001].

This was supported by a study finding that an unspecified extract did not inhibit binding to NMDA receptors. However, hypericin did bind to NMDA receptors with moderate affinity (K_i approximately 1 µg/mL) [Cott 1997].

No inhibition of binding to rat NMDA receptors was observed for the constituents hypericin, hyperforin, pseudohypericin, amentoflavone, quercitrin, isoquercitrin, hyperoside and miquelianin [Butterweck 2002b].

In contrast, a hydromethanolic (80%) extract inhibited radioligand binding (CGP 39653) to NMDA receptors with an IC_{50} of 7.0 ± 2.7 µg/mL [Wonnemann 1997].

Hyperforin (at 10 µM) inhibited NMDA-induced calcium influx in rat cortical neurons demonstrating binding and antagonistic activity at NMDA receptors. In hippocampal preparations from male Wistar rats, hyperforin inhibited NMDA-receptor-mediated release of choline from phospholipid membrane [Kumar 2006].

Oestrogen receptors
Binding of oestradiol to the oestrogen receptor (ERα) was weakly inhibited (IC_{50} 200 µg/mL) by an ethanolic (50%) extract. Oestrogen binding to ERα receptor was inhibited by biapigenin (IC_{50} 1 µM) [Simmen 1999]. Other flavonoids did not significantly inhibit binding to ER-α (IC_{50} > 10 µM) [Simmen 1999; Simmen 2001].

Opioid receptors
An affinity of 1 µM hypericin with more than 40% inhibition was shown for non-selective muscarinic cholinergic receptors and for non-selective σ-opioid receptors [Raffa 1998].

Binding of [^{3}H]-naloxone to human recombinant µ- and κ-opioid receptors was inhibited by an ethanolic (50%) extract with IC_{50}-values of 25 – 40 µg/mL and 90 – 200 µg/mL respectively. The extract was approximately 10 times less active than a methanolic extract with approximately 0.2% hypericin and 5% hyperforin. Corresponding activity was observed for the hexane fraction of the ethanolic extract containing phloroglucinols, and the pure compounds hyperforin and adhyperforin. Hypericin and pseudohypericin inhibited binding to opioid receptors at 1-4 µM. No activity was observed with procyanidins, rutin, hyperoside, isoquercitrin, quercitrin, quercetin and I3,II8-biapigenin at concentrations of 10 µmol/mL [Simmen 1999; Simmen 2001; Simmen 1998].

In a screening of an ethanolic extract, binding of radiolabelled ligands was strongly inhibited at the opioid receptors µ (IC_{50} 4 µg/mL), κ (IC_{50} 3 µg/mL) and δ (IC_{50} 5 µg/mL) [Simmen 1999].

A hydromethanolic extract (0.5% hypericin, 4.5% hyperforin and 0.4% biapigenin) and a CO_2 extract (0.1% hypericin, 24% hyperforin and trace amounts of biapigenin) only weakly inhibited ligand binding at rat brain cortex σ-receptors. Hypericin showed an inhibition IC_{50} of 2.8-7.3 nM. The effect was light-dependent, with increasing IC_{50}-values under exclusion of light. Hyperforin did not inhibit ligand binding at rat brain cortex σ-receptors [Gobbi 2001].

In contrast, a methanolic extract with approximately 0.2% hypericin and 5% hyperforin inhibited binding to opioid receptor sub-types µ, κ and δ at low micromolar ranges. Corresponding activity was also observed for hyperforin and adhyperforin [Simmen 2001].

At a concentration of 10 µM neither hypericin nor pseudohypericin inhibited binding to the human opioid δ receptor. A slight inhibition was found for hypericin at the µ-receptor, and for pseudohypericin at the κ-receptor. No binding at opioid receptors was determined for quercitrin, isoquercitrin, rutin, hyperoside and miquelianin. Binding to opioid receptor δ was inhibited by amentoflavone (75%, K_i of 36.5 ± 14 nM) [Butterweck 2002b].

Serotonin receptors
After fractionation of an ethanolic (50%) extract the most distinct inhibition of binding was found at the 5-HT_6 (IC_{50} 1 µg/mL) and 5-HT_7 (IC_{50} 4 µg/mL) receptors for the hexane fraction containing hyperforin-related compounds, whereas the CH_2Cl_2 (pigments) and methanolic fractions (flavonoids and hypericins) were less active. Hypericin inhibited binding with an IC_{50} of 6 µM at 5-HT_6, and an IC_{50} > 10 µM at 5 HT_7. Hyperforin inhibited binding to 5-HT_6 (IC_{50} of 2 µM) and 5-HT_7 (IC_{50} of 3 µM). Flavonoids and I3,II8-biapigenin did not exhibit any effect on ligand binding to the serotonin receptors 5-HT_6 and 5-HT_7 at concentrations up to 10 µM [Simmen 1999; Simmen 2001]

A methanolic (80%) extract inhibited binding to 5-HT_{1A}-receptors with an IC_{50} of approximately 50 µg/mL [Rolli 1995].

A methanolic (80%) extract had a slight effect on binding to mouse brain 5-HT_2 receptors at a concentration of 100 µg/mL [Müller 1996].

An unspecified extract from fresh flowers and buds (containing approximately 0.1% of hypericin) showed 54% inhibition of binding (K_i = 25 µg/mL) to the 5-HT_1 receptor [Cott 1997].

A hydromethanolic extract (0.5% hypericin, 4.5% hyperforin and 0.4% biapigenin) and a CO_2 extract (0.1% hypericin, 24% hyperforin and trace amounts of biapigenin) did not inhibit ligand binding at recombinant rat 5-HT_6 and 5-HT_7 receptors [Gobbi 2001].

Amentoflavone (10 µmol/L) inhibited binding to the 5-HT_{1D} receptor (85%). Inhibition at the rat 5-HT_{2C} receptor was weaker (46%) [Butterweck 2002b].

Other receptors
A hydromethanolic extract (0.5% hypericin, 4.5% hyperforin and 0.4% biapigenin) and a CO_2 extract (0.1% hypericin, 24% hyperforin and trace amounts of biapigenin) did not inhibit ligand binding at neuropeptide NPY_1 and NPY_2 receptors from rat brain cortex and rat brain hippocampus respectively [Gobbi 2001].

Either no or weak inhibition of binding to histamine H_1 receptors was found for an ethanolic (50%) extract, hypericin at 1 µM, hyperforin at 10 µM, and the flavonoids amentoflavone, quercitrin, isoquercitrin, hyperoside and miquelianin [Butterweck 2002b].

Hypericin at 1 µM had no significant activity (<10%) at the rat adenosine A_1 and A_2-receptors, the rat angiotensin AT_1 receptor, the cloned human bradykinin B_2 receptor, the unspecific mouse glucocorticoid receptor and the rat vasopressin V_1 receptor. Weak affinity was found at the rat CCK_A-receptor and the cloned human endothelin ET_A-receptor [Raffa 1998].

No inhibition of binding to nicotinic, prostanoid, vasopressin receptors V_1-V_3 and oxytocin receptors was found for hypericin, pseudohypericin, amentoflavone, quercitrin, isoquercitrin, hyperoside and miquelianin [Butterweck 2000].

Effects on receptor regulation
Exposure of confluent rat astrocytoma C6 cell cultures to an ethanolic (50%) extract over 8 days resulted in a dose-dependent β-adrenoreceptor (AR) down-regulation equal to desipramine [Kientsch 2001].

A dry extract (DER: 4-7:1; ethanol 57.9% V/V) demonstrated a reduction in β-AR numbers in cultured cells comparable with desipramine (DMI) and fluoxetine (FLU). Seven-day incubation of cell cultures with DMI resulted in a reduction of β-AR numbers of 65 ± 6% ($p<0.01$), an effect fully reversed by co-incubation with 100 µM α-tocopherol. The extract led to a down-regulation of 56 ± 9% compared to untreated controls ($p<0.001$). On co-incubation with α-tocopherol, receptor down-regulation was significantly inhibited (88.6±5.3% of control, $p<0.001$) following exposure to the extract [De Marchis 2006].

Pre-incubation of rat C6 glioblastoma cells with hyperforin and hyperoside for 3 days led to a significant reduction in β_2-AR sensitivity, comparable to desipramine, and a loss of cAMP generation after β_2-stimulation with terbutaline ($p<0.05$) [Prenner 2007].

Similar results were obtained with a methanolic (80%) extract, which caused a dose-dependent reduction in the expression of serotonin (5-HT) receptors in a rat neuroblastoma cell line (PC-12) after short-term exposure over 2 to 6 hours [Müller 1993].

In a further study, the same extract affected cellular mRNA levels of the glucocorticoid receptors GR_α and its inhibitory counterpart GR_β at clinically relevant concentrations of hyperforin (125 ng/mL) via a primary and transient up-regulation of GR_α mRNA levels (at a concentration of 2.5 µg/mL) and a down-regulation of GR_β mRNA levels (at a concentration of 10 µg/mL) after 16 h of treatment [Enning 2011].

Neurotransmitter re-uptake inhibition
Inhibition of neurotransmitter re-uptake from the synaptic cleft has long been assumed to be the principal biochemical mechanism underlying the therapeutic effects of antidepressants such as tricyclic antidepressants, selective 5-HT re-uptake inhibitors (SSRIs), norepinephrine (NE) re-uptake inhibitors (NRIs) and 5-HT–NE reuptake inhibitors (SNRIs).

A methanolic (80%) extract inhibited serotonin re-uptake by rat synaptosomes with an IC_{50} of 6.2 µg/mL [Perovic 1995].

In mice synaptosomal preparations a CO_2 extract (38.8% hyperforin) demonstrated pronounced reuptake inhibition of 5-HT (IC_{50} 0.26 µg/mL), NE (IC_{50} 0.25 µg/mL), DA (IC_{50} 0.056 µg/mL), GABA (IC_{50} 0.12 µg/mL) and glutamate (IC_{50} 2.83 µg/mL) and for hyperforin (IC_{50} 0.11 µg/mL). IC_{50} values of a methanolic extract (1.5% hyperforin) were about 10 times higher than those of the CO_2 extract [Chatterjee 1998a].

A hydromethanolic extract (hyperforin content < 5%) inhibited the accumulation of [^{3}H]-5-HT in rat brain cortical synaptosomes with an IC_{50} of 7.9 µg/mL, compared to 1.8 µg/mL for hyperforin. The extract at 3-10 µg/mL and hyperforin at 0.3-1 µg/mL induced marked tritium release from synaptosomes preloaded with [^{3}H]-5-HT [Gobbi 1999].

A hydromethanolic extract (0.3% hypericin, 4.9% hyperforin) dose-dependently inhibited 5-HT and NE uptake in astrocytes with IC_{50} values of 25 µg/mL and 10 µg/mL respectively [Neary 1999]. Another hydromethanolic extract inhibited synaptosomal uptake of 5-HT, DA and NE with IC_{50} values of 2.43, 0.85 and 4.47 µg/mL respectively [Müller 1997].

Hyperforin was tested on voltage- and ligand-gated ionic conductances to measure neuronal responses to stimulation of NMDA or AMPA (α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid) receptors. At concentrations between 3 and 100 µM, antagonistic effects on the NMDA receptor and on responses mediated by AMPA or GABA were seen [Chatterjee 1999]. Hyperforin non-competitively inhibited the synaptosomal uptake of [^{3}H]-glutamate and [^{3}H]-GABA [Wonnemann 2000].

An ethanolic (50% m/m) extract led to a dose-dependent

inhibition of NE- and 5-HT-uptake into rat brain slices. The extract was more selective for the uptake of NE than for that of 5-HT. The maximal extent of uptake inhibition by the extract was comparable to that of the positive controls imipramine, desimipramine and fluvoxamine, but lower for NE transport than the controls [Kientsch 2001].

A study assessed the effects on neurotransmitter reuptake of two different extracts (extracts 1 and 2: 3.34% and 0.56% hyperforin, 0.59% and 0.05% adhyperforin, respectively), methanolic and *n*-heptane fractions, as well as purified hyperforin and adhyperforin. Adhyperforin was shown to have a slightly more potent inhibitory effect than hyperforin on the uptake of DA (IC_{50} 1.8 and 6 ng/mL), 5-HT (IC_{50} 15 and 65 ng/mL) and NE (IC_{50} 7.9 and 18 ng/mL) [Jensen 2001].

A methanolic (80%) extract inhibited uptake of 5-HT and NE in cultures of rat cortical astrocytes. The extract also inhibited 5-HT uptake in neuronal cultures from serotonergic-rich raphe nuclei. The extract was 25 times more potent in inhibiting 5 HT uptake in neurons than in astrocytes. The extract also inhibited NE re-uptake in SK-N-SH cells, a human neuroblastoma cell line enriched in NE transporters. Hyperforin was about 10 to 20 times more potent than the extract in inhibiting neurotransmitter uptake in astrocytes and neuronal cells; this is consistent with the concentration of 5% hyperforin in the extract. The extract stimulated a persistent activation of extracellular signal regulated protein kinase (ERK) [Neary 2001].

The effects of a methanolic (80%) extract (10 µg/mL) and pure hyperforin (300 nM) on human blood platelet 5-HT uptake and efflux were compared to those of amitriptyline (AMI), venlafaxine (VEN), and reserpine. In contrast to AMI and VEN, the extract and hyperforin did not inhibit 5-HT uptake in platelet-rich plasma. In contrast to controls and AMI, a loss of accumulated [^{14}C]-5-HT after a prolonged incubation period was observed, suggesting that both hyperforin and the extract might affect the storage of 5 HT in platelet vesicles. In the presence of a comparably high concentration of reserpine (2.5 µM), the degree of 5-HT depletion in storage vesicles was lower than in the presence of 1 µM hyperforin [Uebelhack 2001].

The effect of hyperforin on 5 HT re-uptake was examined in Sprague-Dawley rat cortex synaptosomal preparations. Total re uptake of radiolabelled choline was significantly inhibited by 10 µM hyperforin (-32%, $p<0.05$). The effect was exclusively based on the high affinity system, but not the non-sodium-dependent low affinity re-uptake (total inhibition 68%, IC_{50} of hyperforin 8.5 µM) [Buchholzer 2002].

A hyperforin-rich heptane extract inhibited the sodium-dependent uptake of 5-HT, DA and NE into rat brain synaptosomes. Hyperforin inhibited the uptake of all three monoamines non-competitively, which was in contrast to the competitive inhibition exhibited by FLU, GBR12909 and DMI. Hyperforin had no inhibitory effect on the binding of [^{3}H]paroxetine, [^{3}H]-GBR12935 and [^{3}H]-nisoxetine to membrane presynaptic transporters for 5-HT, DA and NE respectively. Hyperforin also non-competitively inhibited the uptake of these monoamines to rat brain synaptic vesicles but did not affect the direct binding of [^{3}H]-dihydrotetrabenazine, a selective vesicular monoamine transporter ligand, to rat forebrain membranes [Roz 2002].

The mechanism of inhibition of synaptic vesicle transport of monoamines by hyperforin was investigated. Since the pH gradient across the synaptic vesicle membrane, induced by vacuolar type H^+-ATPase, is the major driving force for vesicular monoamines uptake and storage, proton transport was measured. Adding Mg-ATP to the medium containing and synaptic vesicles caused an immediate decrease in fluorescence and the addition of 1 µM carbonyl-cyanide *p*-trifluromethoxyphenylhydrazone (FCCP) abolished this effect. H^+-ATPase dependent proton pumping was inhibited by hyperforin in a dose dependent manner (IC_{50} = 1.9×10^{-7} M). Hyperforin acted similarly to the protonophore FCCP, abolishing the ATP induced fluorescence quenching (IC_{50} = 4.3×10^{-7} M). Hyperforin and FCCP had similar potencies for inhibiting rat brain synaptosomal uptake of [^{3}H]-monoamines as well as vesicular monoamine uptake. The efflux of [^{3}H]-5-HT from synaptic vesicles was sensitive to both drugs, thus 50% of preloaded [^{3}H]-5-HT was released in the presence of 2.1×10^{-7} M FCCP and 4×10^{-7} M hyperforin [Roz 2003].

The efficacy of different commercial extracts was investigated by measuring their activity to inhibit 5-HT uptake. The products with different concentrations of pharmaceutically relevant ingredients also differed in their IC_{50} values between 3.07 and 17.9 µg/mL. The activity of the products was correlated to their amount of hyperforin ($p<0.05$) [Schulte-Löbbert 2004].

The immediate effects of an ethanolic extract (50% m/m) with a low content of hyperforin on the specific DA uptake were studied in rat striatal brain slices and compared with the effects on NE and 5-HT uptake in rat cortical brain slices. Specific DA uptake was inhibited in a dose-dependent manner. The NE uptake inhibition was around 30-times higher than that for 5-HT, and seven times higher than that of the DA uptake [Ruedeberg 2010].

Adhyperforin inhibited uptake of [^{3}H]-5-HT, [^{3}H]-NE, and[^{3}H]-DA (IC_{50} 4.1, 2.64, and 0.89 µg/mL, respectively) in synaptosomes of the frontal cortex, and displayed robust binding affinities to the 5-HT, NE but not DA transporters (K_i values 18.75 and 4.03 µg/mL respectively) [Tian 2014].

Membrane interaction

The effects of hyperforin on the fluidity of crude brain membranes from young guinea pigs was investigated using three different fluorescent probes. Diphenylhexatriene (DPH) and trimethylammonium-diphenylhexatriene (TMA-DPH) anisotropy measurements were inversely correlated with membrane flexibility (annular and bulk fluidity). Incubation of brain membranes with 10 µM hyperforin sodium salt resulted in increased DPH ($p<0.05$) and decreased TMA-DPH ($p<0.01$) anisotropy, respectively, indicating that hyperforin modifies specific membrane structures in different ways. It decreases the flexibility of fatty acids in the membrane hydrocarbon core, but fluidises the hydrophilic region of membrane phospholipids. Lower concentrations (0.3 µM) significantly ($p<0.05$) decreased the annular fluidity of lipids close to membrane proteins. However, bulk fluidity was unchanged by this low hyperforin concentration [Eckert 2001].

An ethanolic (60%) extract (containing 5% hyperforin) and hyperforin sodium salt were given at single oral doses of 300 mg/kg or 15 mg/kg, respectively, to female NMRI mice. Three hours later in the isolated brains the properties of murine brain membrane fluidity were determined. Oral administrations resulted in hyperforin brain levels of 29.5 ± 18.7 pmol/g and 53.7 ± 18.7 pmol/g. Treatment of mice with hyperforin lead to decreased annular- ($p<0.05$) and bulk fluidity ($p<0.001$) and increased ($p<0.01$) acyl-chain flexibility of brain membranes [Eckert 2004].

Effects on ion channels

In rat cerebellar Purkinje neurons, hyperforin inhibited ion currents at the NMDA and AMPA receptors (IC_{50} 3.2 µM and 4.6 µM respectively) in a dose- and time-dependent manner [Chatterjee 1999].

Spasmolytic properties of hyperforin were studied in the hamster *vas deferens* smooth muscle cell line DDT1-MF2. Hyperforin (0.3-10 µg/mL) caused a concentration-dependent increase of intracellular calcium concentration ($[Ca^{2+}]_i$) and extracellular acidification rate (ECAR). Both effects were independent of extracellular Ca^{2+}. Since the ECAR stimulation was inhibited by the intracellular Ca^{2+} chelator BAPTA, as well as by inhibitors of plasmalemmal and mitochondrial Na^+/Ca^{2+} exchangers, but not by inhibitors of the Na^+/H^+ antiporter, the intracellular Ca^{2+} increase seems to be essential for this hyperforin effect [Koch 2001].

Isolated patch-clamped rat central and peripheral neurons exposed to rapid changes in the compartment of external medium were used to investigate the modulation of various voltage- and ligand-gated channels by hyperforin and other constituents of *Hypericum perforatum*. At nanomolar concentrations, hyperforin induced inhibition of various ion channels. On P-type Ca^{2+} channels hyperforin acted via interaction with calmodulin or through calmodulin-activated pathways involving at least one second messenger [Krishtal 2001].

In rat PC12 cells, hyperforin (10 µM) increased intracellular concentrations of Na^+ and Ca^{2+}. This increase was dependent on the activation of a non-selective cation channel, TRPC6, a transient receptor potential channel. Blockade of TRPC6 channels inhibited the hyperforin effect in PC12 cells [Leuner 2007]. This was confirmed by experiments in cortical neurons from embryonic murine brain [Gibon 2010].

Hyperforin inhibited various ion channels in the patch-clamp model in peripheral and central neuronal cells isolated from Wistar rats. In P-type Ca^{2+} channels it was confirmed that hyperforin acts via an interaction with calmodulin or through calmodulin-activated pathways involving at least one second messenger. An extract (5% hyperforin) inhibited almost all tested ligand-gated ion channels. Quercitrin was detected as a potent inhibitor of ATP-induced conductance; biapigenin and hyperoside inhibited ATP- and AMPA-induced conductances, whereas hypericin was inactive in all cases [Krishtal 2001; Leuner 2007; Treiber 2005; Wang 2010].

The effect of an unspecified extract and hypericin on cell viability, human chorionic gonadotrophin (hCG) production, Ca^{2+} uptake, and Ca^{2+} transport proteins expression in JEG-3 cells was analysed. Toxicity was seen at high concentrations (≥150 µg/mL), but with no effect on hCG production with the extract (25 µg/mL) or hypericin (7.5 and 75 ng/mL). Cells treated with the extract or hypericin exhibited increased intracellular Ca^{2+} concentrations after 24 h but not 10 min of incubation. A significant ($p<0.01$) decrease in translationally controlled tumour protein Ca^{2+} handling protein was only caused by the extract. Hypericin increased the protein expression of the transient receptor potential vanilloid 6 Ca^{2+} channel and 28-kDa calcium-binding protein and decreased that of plasma membrane Ca^{2+}-ATPase 1/4 [da Conceicao 2010].

Hyperforin induced TRPC6-independent H^+ currents in HEK-293 cells, cortical microglia, chromaffin cells and lipid bilayers. The latter demonstrated that hyperforin acts as a protonophore. This activity caused cytosolic acidification, which strongly depended on the holding potential, and fueled the plasma membrane sodium-proton exchanger. Thereby the free intracellular sodium concentration increased and the neurotransmitter uptake by Na^+ co-transport was inhibited. Additionally, hyperforin depleted and reduced loading of large dense core vesicles in chromaffin cells, which requires a pH gradient in order to accumulate monoamines [Sell 2014].

Neutrophils from patients with Behçet's disease (BD) were divided into three subgroups and incubated with either an unspecified extract (containing 3.6% hyperforin), voltage-gated calcium channel (VGCC) blockers (verapamil+diltiazem, V+D) or a non-specific TRPM2 channel blocker (2-aminoethyl diphenylborinate, 2-APB). They were subsequently stimulated with fMLP as a Ca^{2+} agonist and oxidative stress generator. The high cytosolic-free Ca^{2+} $[Ca^{2+}]_i$, caspase-3, and caspase-9 values found in the patient groups decreased markedly after treatment with the extract and low GSH and GSH-Px values increased. The $[Ca^{2+}]_i$ also decreased in the groups with V+D and 2-APB incubations. The extract induced protective effects on oxidative stress by modulating Ca^{2+} influx in BD patients. [Naziroglu 2014a; Naziroglu 2014b].

Cholinergic effects

The effect of hyperforin on choline (Ch) uptake was studied in brain synaptosomes from Sprague-Dawley rat cortices. Hyperforin inhibited high-affinity choline uptake with an IC_{50} of 8.5 µM, whereas low-affinity uptake was not affected [Buchholzer 2002].

The spontaneous release of Ach in the neuromuscular junction of Charles River male mice was unaffected by a hydroalcoholic extract at doses from 0.2 to 1.0 mg/mL indicating that neither presynaptic nor postsynaptic functions were modified by the extract. Both the frequency and amplitude of the miniature end-plate currents (mepcs) were unmodified by the extract. The mepcs decay time, i.e. the apparent cholinergic channel life time, was significantly increased after treatment. The amplitude of the evoked end-plate currents was constantly and in a dose-dependent manner increased by the extract [Re 2003].

Smooth muscle function

Contractions of rat bladder strips were induced by electrical field stimulation (EFS) or by exogenous α,β-methylene ATP. An unspecified hydromethanolic extract was significantly ($p<0.001$) more active in inhibiting the EFS-induced contractions than the α,β-methylene ATP-induced contractions. The inhibitory effect of the extract on EFS-induced contractions was unaffected by methysergide, haloperidol, phentolamine and propranolol (antagonists blocking the action of 5-HT, DA, and NE on their own receptors), the L-type calcium channel antagonist verapamil, capsazepine (blocking the vanilloid receptor), or cannabinoid CB_1 receptor antagonist SR141716A. However, the opioid receptor antagonist naloxone significantly ($p<0.001$) reduced the inhibitory effect of the extract on EFS-induced contractions [Capasso 2004].

An unspecified hydromethanolic extract (1-300 µM) exhibited a concentration-dependent decrease in the amplitude of contractions in isolated rat and human *vas deferens* induced by both EFS and α,β-methylene ATP [Capasso 2005].

Immunological effects

A hydromethanolic extract caused pronounced suppression of interleukin-6 (IL-6) release in human blood samples after stimulation with phytohaemagglutinin [Thiele 1993]. Hypericin at the micromolar range inhibited phorbol myristate acetate- and TNF-α-induced activation of NF-κB, whereas hyperforin and an ethanolic extract (60%, w/w; 0.15% hypericin and 5% hyperforin) were inactive [Bork 1999]. The myeloperoxidase-catalysed dimerisation of enkephalins was inhibited by a methanolic extract [Denke 1999].

Mononuclear cells from healthy donors were incubated with a hydromethanolic extract or with SSRIs and tested for natural killer cell activity. The extract was tested at very low concentrations (0.5-20 ng/mL), paroxetine (PAR) at 120 ng/mL

and norfluoxetine at 100 ng/mL. In contrast to the SSRIs, the extract failed to enhance natural killer cell activity at these concentrations [Helgason 2000].

Seven unspecified commercial extracts were studied for their effect on substance P (SP)-induced synthesis of IL-6 in human astrocytoma cells. A potent and dose-dependent inhibition of SP-induced IL-6 synthesis by various extracts was demonstrated [Fiebich 2001].

Autoimmune inflammatory demyelination
Hyperforin inhibited IFN-γ production, with down-regulation of a Th1 gene expression marker and upregulation of a Th2 marker, on IL-2/PHA-activated T cells. In parallel, a strong down-regulation of the chemokine receptor CXCR3 expression on activated T cells was shown. *In vivo*, hyperforin (150 mg/kg in food pellets) significantly ($p<0.001$) attenuated the severity of symptoms of experimental allergic encephalomyelitis, a Th1-mediated autoimmune disease of the CNS [Cabrelle 2008].

Neuroprotection
The effect of hyperforin was studied on the processing of the amyloid precursor protein (APP) in PC12 cells, stably transfected with human wild type APP. A transiently increased release of secretory APP fragments was observed upon hyperforin treatment (50 nM - 10 μM). These results suggest that hyperforin is an activator of secretory processing of APP [Froestl 2003].

The neuroprotective role of an ethanolic (80%) extract and hexane, ethyl acetate, and butanol fractions in amyloid-β peptide (Aβ)-induced cell death in rat cultured hippocampal neurons was investigated. Induced lipid peroxidation was significantly ($p<0.05$) inhibited by fractions containing flavonol glycosides, flavonol and biflavone aglycones, and by a fraction containing mainly chlorogenic acid-type phenolics (21%, 77% and 98% respectively). Lipid peroxidation evaluated after incubation with 25 μM Aβ, was significantly ($p<0.05$) inhibited by the extract. The extract, and fractions containing flavonol glycosides, flavonol and biflavone aglycones, reduced Aβ-induced cell death by 65%, 58% and 59% respectively. Aβ induced a decrease in cell volume, chromatin condensation and nuclear fragmentation, effects not evident in the presence of the extract and fractions containing hypericins (hypericin = 11.0 μM), or fractions containing flavonoids (quercetin = 21.1 μM). Dendritic lesions were observed following insult with Aβ, but prevented after exposure to the peptide plus the fractions [Silva 2004].

An unspecified extract protected PC12 cells from H_2O_2-induced damage in a dose-dependent manner within 24-hour treatment. Intra- and extra-cellular ROS levels decreased significantly to 71.9% and 50.0% of the control at 20 μg/mL, respectively. The extract blocked DNA fragmentation and prevented H_2O_2-induced apoptosis of the cells at concentrations of 10 to 100 μg/mL [Lu 2004].

An ethanolic extract (50% V/V; 0.37% hypericins, 10.1% total flavonoids and 0.7% hyperforin) was evaluated for its antioxidative properties in glutamate-induced cell death of hippocampal HT22 cells. The maximum protective effect was observed at 0.1%. The effects were related to an attenuation of calcium fluxes and cellular energy statuses [Breyer 2007].

In a microglial cell line pre-treated with an ethanolic (50%) extract, cell death evoked by treatment with $Aβ_{25-35}$ and $Aβ_{1-40}$ was attenuated significantly ($p<0.01$ to $p<0.001$) in a dose-dependent manner. Investigation of the single compounds revealed that (+) catechin and (-)-epicatechin increased cell viability slightly, whereas the quercetin, rutin, hyperoside and quercitrin showed no effect on cell viability. At the same concentration, the flavonoids reduced the formation of amyloid-induced ROS in microglia. No influence of the extract on the capacity of microglia to phagocytose sub-toxic concentrations of fibrillar $Aβ_{1-40}$ was observed [Kraus 2007].

The neuroprotective effect of a methanolic extract was investigated in astrocytes from male Swiss albino mice. Treatment with the extract for 7 days (300 mg/kg/day p.o.) following a challenge on day 1 with 4 i.p. injections of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) (20 mg/kg in 2 h intervals) resulted in reduced MPTP-induced striatal area astrocyte activation and a signfiicant inhibition of MAO-B activity ($p<0.05$) compared to MPTP alone [Mohanasundari 2007].

Quercetin, kaempferol and biapigenin significantly ($p<0.05$) reduced chemically induced neuronal death in hippocampal neurons from Wistar rat embryos. Neuroprotection was correlated with prevention of delayed calcium deregulation and with the maintenance of mitochondrial transmembrane electric potential in brain mitochondria. The compounds reduced mitochondrial lipid peroxidation ($p<0.05$ to $p<0.01$) and loss of mitochondrial transmembrane electric potential caused by oxidative stress. Biapigenin significantly ($p<0.05$) affected mitochondrial function and decreased the capacity of mitochondria to accumulate calcium [Silva 2008a].

Hypericin significantly interacted with peptides in β-sheet conformation by hindering the formation of fibrils and thereby interfering with early stages of the polymerisation process responsible for neurodegenerative disorders [Bramanti 2010].

An unspecified extract (31.25 ng/mL-5 μg/mL) significantly ($p<0.05$) decreased the survival of human SH-SY5Y neuroblastoma cells at the highest dosage, whereas lower concentrations exerted no significant effects. The treatment of cells with 5 μg/mL led to a significant ($p<0.05$) increase of ATP levels, whereas treatment with a concentration of 500 ng/mL had no significant effect. The extract did not show any cytotoxic activity [Schmidt 2010].

Quercetin and kaempferol stimulated depression-related signalling pathways involving brain-derived neurotrophic factor (BDNF), phosphorylation of cAMP response element binding protein (CREB), postsynaptic density proteins PSD95, and reduced amyloid-β peptide (Aβ) in neurons isolated from double transgenic AD mice (TgAPPswe/PS1e9). In addition, enhanced BDNF expression and reduction of Aβ oligomers were confirmed in the hippocampus [Hou 2010].

Hyperoside (2.5, 5, 10 or 20 μM) significantly inhibited cytotoxicity and apoptosis in $A\text{-}β_{25-35}$-induced primary cultured cortical neurons from embryonic Sprague-Dawley rat foetuses by reversing $A\text{-}β_{25-35}$-induced mitochondrial dysfunction, including mitochondrial membrane potential decrease, ROS production ($p<0.01$), and mitochondrial release of cytochrome c ($p<0.01$). The compound activated the PI3K/Akt signalling pathway, resulting in inhibition of the interaction between Bad and Bcl_{XL} and inhibited the mitochondria-dependent downstream caspase-mediated apoptotic pathway ($p<0.05$ to $p<0.01$). It protected Aβ-induced primary cultured cortical neurons via PI3K/ Akt/ Bad/ Bcl_{XL}-regulated mitochondrial apoptotic pathway [Zeng 2011].

An ethanolic extract (60% V/V; 0.3% hypericin and 0.61% hyperforin) administered to male Wistar rats for 21 days at a dose of 300 mg/kg per day demonstrated increased mRNA levels for mdr1 by 275% ($p<0.001$), for oatp1c1 by 41% ($p<0.05$), and a reduced mRNA level (by 68.5%, $p<0.05$)) for mrp1 in hippocampal tissue [Mrozikiewicz 2014].

Anti-inflammatory effects
Hypericin (1, 5, 10 µg/mL) significantly ($p<0.05$) and dose-dependently inhibited IL-12 production in LPS-activated macrophages from female DBA/2 mice (IC_{50} = 1.45 µg/mL) and potently inhibited the activation of an IL-12 gene promoter [Kang 2001].

A methanolic (80%) extract and hyperforin (0.03, 0.1, 0.3, 1, 3 and 10 µM) were investigated for inhibition of 5-lipoxygenase (5-LO) and cyclooxygenases (COX). Hyperforin directly inhibited 5-LO (IC_{50} ~ 90 nM) in freshly isolated human polymorphonuclear leukocytes (PMNL). In thrombin- or ionophore-stimulated human platelets, hyperforin suppressed COX-1 activity with IC_{50} values of 0.3 and 3 µM respectively, being about 3- to 18-fold more potent than aspirin. Hyperforin did not interfere with COX-2 product formation and did not significantly inhibit 12-LO in platelets or 15-LO in leukocytes. Inhibition of 5-LO was slightly more prominent for equimolar amounts of the extract (calculated for hyperforin; IC_{50} 22 µg/mL) [Albert 2002].

A methanolic (80%) extract exhibited antiinflammatory activity on PMNL myeloperoxidase (MPO) activity. The extract reduced the peroxidative and chlorinating activity of MPO in a concentration-dependent manner by 18.5% (at 20 µg/mL) to 44.1% (at 40 µg/mL) [Pabuccuoglu 2003].

Hyperoside exerted an anti-inflammatory action through suppressed production of TNF-α, IL-6, and NO in LPS-stimulated mouse peritoneal macrophages. The maximal inhibition rates of TNF-α, IL-6, and NO production by 5 µM hyperoside were 32.31 ± 2.8%, 41.31 ± 3.1%, and 30.31 ± 4.1% respectively. In addition, hyperoside inhibited NF-κB activation and IκB-α degradation [Kim 2011].

Various extracts (acetonic, 96% ethanolic and 50% ethanolic) and isolated constituents (flavonoids and dianthrones) showed a comparable and dose-dependent inhibition (>80% inhibition at 0.15%) of 5-LO. The strongest effect was seen for hyperoside (IC_{50} 3.89×10^{-6} M), whereas quercetin, quercitrin, isoquercitrin and rutin were less active (IC_{50} of $3.7 – 9.0 \times 10^{-5}$ M). The weakest effects were seen for hypericin and pseudohypericin (IC_{50} of 1.5 and 6.3×10^{-4} M) [Oblozinsky 2006].

In isolated PMNL hyperforin inhibited the generation of reactive oxygen species (ROS) as well as the release of leukocyte elastase with an IC_{50} of about 3 µM and blocked receptor-mediated Ca^{2+} mobilisation (IC_{50} 0.4 and 4 µM) in PMNL and monocytic cells [Feisst 2004].

The inhibition of prostaglandin E_2 (PGE_2) production by various extracts and some constituents was investigated in RAW 264.7 mouse macrophage cells. The anti-inflammatory activity of all extracts was light-independent. The extracts significantly reduced LPS-induced PGE_2 production by 73 to 82% (each $p<0.0001$) [Hammer 2007]. An extract fraction used in the previous study, and a combination of four synergistic constituents at levels identified from that fraction called the 4 component-system (0.07 µM amentoflavone, 0.08 µM quercetin, 0.2 µM chlorogenic acid and 0.03 µM pseudohypericin), were studied to identify key gene targets involved in the anti-inflammatory activity. The reduction in PGE_2 in LPS-stimulated macrophages observed with both treatments may be accounted for by genes involved in Janus kinase, as well as a signal transducer and activator of transcription (JAK–STAT) and eicosanoid pathways. COX-2 appeared to be a major target of both the 4-component-system and the fraction, and upstream pathways leading to COX-2 expression were also affected by both treatments [Hammer 2010].

The inhibitory effect of the 4 component system on LPS-induced prostaglandin E_2 and NO production in RAW 264.7 mouse macrophages was compared to ethanolic extracts and extract fractions. Pseudohypericin was found to be the most important for anti-inflammatory activity. Most of the extracts reduced LPS-induced PEG_2 and NO production [Huang 2012].

Hyperoside exerted an anti-inflammatory effect through inhibition of iNOS expression and suppressed production of TNF-α, IL-6 and NO in LPS-stimulated mouse peritoneal macrophages. Furthermore, it inhibited NFκB activation by inhibiting LPS-induced degradation of the inhibitory subunit IκB-α, a key step for NFκB-induced transcription of certain proinflammatory genes including iNOS [Kim 2011].

An unspecified extract was studied at doses of 10, 25 and 50 µg/mL on adipocyte differentiation and for anti-inflammatory effects in 3T3-L1 pre-adipocytes. The extract promoted adipocyte differentiation, while immunoblots indicated that the extract increased the expression of peroxisome proliferator activated receptor gamma (PPARγ), a nuclear receptor regulating adipocyte differentiation, and adiponectin, an anti-inflammatory adipokine. The anti-inflammatory activity of the extract was demonstrated by its inhibition of the activation of NF-κB. Stimulation of mature 3T3 L1 adipocytes by TNF-α decreased the expression of the NF-κB inhibitor IκBα, and increased its phosphorylation. Treatment with the extract decreased the TNF-α induced perturbation in IκBα expression and phosphorylation, indicating that the extract mediated the inhibition of NF-κB activation. In addition, the extract decreased the TNF-α induced increase in the mRNA levels of pro-inflammatory adipokines, IL-6, and monocyte chemoattractant protein-1 [Hatano 2014].

Tissue repairing effects
The tissue repairing effects of an alcoholic (50%) extract were evaluated in comparison with dexpanthenol on cultured chicken embryonic fibroblasts. The extract exhibited a tissue repairing activity mainly due to an increase in the stimulation of fibroblast collagen production and the activation of fibroblast cells in polygonal shape [Öztürk 2007].

Metabolic effects
In the INS-1E β-cell line an unspecified hydroalcoholic extract and hyperforin (at 1-3 µM) prevented cytokine (IFN-γ, 150 U/mL + IL-1β 10 U/mL + TNF-α 50 U/mL) induced impairment of glucose-stimulated insulin secretion, and protected cells against apoptosis in a dose-dependent manner. iNOS expression ($p<0.05$) as well as cytokine-induced activations of STAT-1 and NF-κB were down-regulated by the extract and hyperforin (range 0.5-5 µM) [Menegazzi 2008].

Ethanolic extracts, one from leaves and one from flowers, inhibited differentiation of 3T3-L1 adipocytes. Both extracts substantially inhibited insulin sensitive glucose uptake in mature 3T3-L1 adipocytes. Treatment with the flower extract resulted in a time- and dose-dependent inhibition of insulin stimulated glucose uptake in mature adipocytes [Amini 2009].

An unspecified flower extract at a dose of 50 µg/mL significantly ($p<0.02$) reduced insulin-sensitive glucose uptake in human adipocytes compared to control. The extract inhibited insulin receptor substrate-1 (IRS-1) tyrosine phosphorylation in both murine and human fat cells. Hypericin (0.02–0.3 µM) and hyperforin (0.17–2.8 µM) did not modulate adipocyte development and insulin activity in mature adipocytes [Richard 2012].

A hydroalcoholic extract (4.1% hyperforin) at doses of 100 and 200 µg/mL and hyperforin at 1 and 2 µM were applied to

isolated rat and human islets exposed to cytokines (rat or human IFN-γ 1000 µg/mL + IL-1β 100 U/mL + TNF-α 1000 U/mL) over 20 h. In both rat and human islets, the extract and hyperforin counteracted cytokine-induced functional impairment and down-regulated mRNA expression of pro-inflammatory target genes, such as iNOS, CXCL9, CXCL10 and COX-2. Cytokine-induced NO production from cultured islets was significantly ($p<0.01$ to $p<0.001$) reduced in the presence of the extract and hyperforin. The increase in apoptosis and necrosis following 48-h exposure to cytokines was fully prevented by the extract, but only partially by hyperforin. Ultrastructural morphometric analysis in human islets exposed to cytokines for 20 h showed that the extract or hyperforin avoided early beta-cell damage [Novelli 2013].

Antiviral effects
Hypericin showed antiretroviral activity against equine infectious anaemia virus (EIAV). Treatment with 10 µg/mL hypericin reduced the virus production completely [Kraus 1990].

In primary human lymphocytes hypericin exhibited anti-HIV-1 activity via an inhibition of HIV-1 reverse transcriptase [Schinazi 1990].

Hypericin and protohypericin inhibited virus replication of human cytomegalovirus strain AD-169 in human foreskin (Hs-68) and lung fibroblast cells (MRC-5) with IC_{50} values of 1.8 and 5.7 µM respectively [Barnard 1992].

Hypericin (500 ng/mL) exhibited strong antiviral activity against vesicular stomatitis virus, *Herpes simplex* virus types 1 and 2, parainfluenza virus and vaccinia virus (up to 3.5 $\log_{10}$ reduction of viral production) [Andersen 1991].

Hypericin (0.12 - 0.25 µg/mL) inactivated murine cytomegalovirus, sindbis virus, and human immunodeficiency virus type 1 (HIV-I), especially on exposure to fluorescent light [Hudson 1991].

Hypericin was active against duck hepatitis B virus (DHBV). After 1 h incubation with hypericin at 15 µg/mL, cells stably-transfected with DHBV stopped virus replication for several days, though virus-like particles continued to be released into the culture medium. Hypericin was only slightly virucidal against DHBV, and culture medium from treated cultures did not block initiation of infection when added to DHBV susceptible cultures prior to a challenge with infectious DHBV [Moraleda 1993].

An ethanolic extract at doses of 0.32 to 40 µg/mL was tested for anti-hepatitis B virus (HBV) activity in HepG2 2.2.15 cells. The extract effectively suppressed the secretion of HBsAg and HBeAg in a dose-dependent manner, as well as the extracellular HBV DNA. In addition, the extract selectively inhibited the activity of HBV promoter Fp [Pang 2010].

Antimicrobial effects
Various extracts were evaluated for their antibacterial activity against *Bacillus subtilis*, *P. aeruginosa*, *Sarcina lutea* and *E. coli* at concentrations of 1, 10, 25 and 50 µg/µL. The *n*-hexane and dichloromethane extracts were inactive against all tested organisms. The *n*-butanol and ethyl acetate extracts showed activity against all the tested bacterial strains at concentrations of 25 and 50 µg/µL while the methanolic extract was only active against *B. subtilis* at concentrations 25 and 50 µg/µL [Naeem 2010].

Twenty-one samples of traditionally-prepared and commercial St. John's Wort olive oil macerates were screened for their antimicrobial and antiprotozoal activity. In the antiprotozoal assays, ten of the oils inhibited *Trypanosoma brucei rhodesiense* (IC_{50} 15.9-64.5 µg/mL), while only one oil exerted antimicrobial activity towards *Staphylococcus aureus* (IC_{50} 88.7 µg/mL) [Orhan 2013].

Hypericin (0-2.5 µM) resulted in a dose- and light-dose dependent (1 – 8 J/cm^2) cytotoxicity (cellular destruction and induction of early apoptosis as a prominent mode of cell death) in CNE-2 nasopharyngeal carcinoma cells [Xu 2010].

Various extracts (MeOH; petroleum ether; chloroform, ethyl acetate) showed growth inhibition of Gram-positive bacteria. The ethyl acetate extract was the most active (MIC 12.5 - 50 µg/mL). Incubation of selected microorganisms with flavonoids, hypericins or hyperforins resulted in a growth inhibition by hypericin (MIC 12.5 - >1000 µg/mL), hyperforin (MIC 25 – 100 µg/mL) and its dicyclohexilammonium salt (MIC 25 – 100 µg/mL). Flavonoids appeared to be inactive [Avato 2004].

Photosensitising and photodynamic effects
The methanolic fraction (PMF) of an unspecified extract was examined for activity against urinary bladder carcinoma using the T24 (high grade metastatic cancer) and RT4 (primary low grade papillary transitional cell carcinoma) human bladder cancer cells. PMF was excited using 630 nm laser light. PMF exhibited significant photocytotoxicity in both cell lines at a concentration of 60 µg/mL, with 4-8 J/cm^2 light dose, resulting in apoptosis from 80% to 86%. At 20 µg/mL PMF was not active in either cell line. Photofrin®, a clinically approved photosensitiser, exhibited less photocytotocixity at 4 µg/mL than PMF in both tested cell lines [Stavropoulos 2006].

In human epidermoid carcinoma cells (A431) the time- and dose-dependence of hypericin-photodynamic treatment (PDT)-based induction of cytotoxicity and apoptotic cell death was studied. Induction of apoptosis by hypericin-PDT was dose-dependent with necrotic cell death at higher doses. Time-course analysis of an almost homogenous apoptotic population of cells (at 1.44 J/cm^2) showed a rapid increase in nuclear fragmentation and activation of caspases reaching a maximum 5 hours after irradiation. Using specific caspase substrates, significant activation of caspase-2, -3, -6 and -9 was found. Mitochondrial involvement during hypericin-PDT-induced apoptosis was proven by a rapid reduction of the mitochondrial membrane potential; the level of intracellular adenosine-5'-triphosphate (ATP) remained at control level for up to 6 hr post irradiation suggesting upregulation of glycolysis as a compensating mechanism for energy supply [Berlanda 2006].

The modulation of hypericin-PDT by pre-treatment with *n*-3 and *n*-6 fatty acids was studied in HT-29 and HeLa tumour cells. A stimulation of cytotoxic effects by docosahexaenoic acid (*n*-3) and arachidonic acid (*n*-6) was observed in both cell lines. Treatment with either fatty acids or photodynamic therapy alone induced apoptosis in a dose- and time-dependent manner. The effect was even more striking with the combination applied as pre-treatment with fatty acids prior to PDT. The combination induced changes in membrane lipid composition leading to alteration in cell membrane fluidity. Increased toxicity from the combined treatment was also confirmed by the presence of oxidative stress as demonstrated by ROS production, RNS accumulation and increased presence of lipoperoxides [Kello 2010].

A hydroalcoholic extract was assessed for its anti-proliferative activity in A375 human melanoma cells after irradiation with UVA (1.8 J/cm^2) and demonstrated phototoxicity at IC_{50} 78 µg/mL. The extract caused a dose-related inhibition of NO production in murine monocytic macrophage cell line RAW 264.7 with an IC_{50} of 342 µg/mL [Menichini 2013].

Antiproliferative effects
Hypericin and pseudohypericin showed a strong inhibitory effect on protein kinase C (IC_{50} of 1.7 and 15 µg/mL respectively) which resulted in an anti-proliferative effect in BALB 3T3/H-ras cells with IC_{50} values of 6.3 and 28 µg/mL respectively; associated with an antiretroviral effect [Takahashi 1989].

Rather than stabilising topoisomerase II (topo II) in covalent complexes with DNA (cleavage complexes), hypericin inhibited the enzyme prior to DNA cleavage. The assays indicated that hypericin is a potent antagonist of cleavage complex stabilisation by etoposide and amsacrine. This antagonism appears to be due to the ability of hypericin to intercalate or distort DNA structure, thereby precluding topo II binding and/or DNA cleavage. Supporting its non-DNA damaging, catalytic inhibition of topoisomerase II, hypericin was shown to be equitoxic to both wild-type and amsacrine-resistant HL-60 leukaemia cell lines. Hypericin was incapable of stimulating DNA damage-responsive gene promoters that are activated by etoposide. As with the topo II assay, antagonism of DNA damage stimulated by 30 µM etoposide was evident in leukaemia cells pre-treated with 5 µM hypericin [Peebles 2001].

Photoactivated hypericin and paclitaxel (PXL) similarly increased the activity of caspase-8 and caspase-3. Drug-induced apoptosis was completely blocked by inhibitors of caspase-8 and caspase-3. The involvement of death receptors was analysed using neutralising monoclonal antibodies against Fas (SM1/23), FasL (NOK-2) and TNF-R1 (MAB225), and a polyclonal rabbit anti-human TNF-related apoptosis-inducing ligand (TRAIL) antiserum. TRAIL antibody blocked TRAIL-induced and photo-activated hypericin-induced, but not PXL-induced apoptosis of Jurkat cells. In contrast, PXL-induced, but not hypericin-induced apoptosis was blocked by the SM1/23 and NOK-2 antibodies. Anti-TNF-R1 antibody had no effect. These findings suggest that hypericin photo-induced apoptosis of Jurkat cells is mediated in part by the TRAIL/TRAIL-receptor system and subsequent activation of upstream caspases [Schempp 2001].

Hyperforin inhibited growth of various human and rat tumour cell lines with IC_{50} values between 3 – 15 µM. Treatment with hyperforin resulted in a dose-dependent generation of apoptotic oligonucleosomes, typical DNA-laddering and apoptosis-specific morphological changes. In MT-450 mammary carcinoma cells hyperforin increased the activity of caspase-9 and caspase-3, and hyperforin-mediated apoptosis was blocked by the caspase inhibitor zVAD.fmk. Hyperforin, but not paclitaxel, induced a rapid loss of the mitochondrial trans-membranal potential $\Delta \psi m$, and subsequent morphological changes such as homogenisation and vacuolisation of mitochondria. Hyperforin-mediated mitochondrial permeability transition was not prevented by zVAD.fmk. The compound was capable of releasing cytochrome *c* from isolated mitochondria. These findings suggest that hyperforin activates a mitochondria-mediated apoptosis pathway [Schempp 2002a].

Photoactivated hypericin did not cause Bcl-2 degradation but induced Bcl-2 phosphorylation in a dose- and time-dependent manner in HeLa cells. Bcl-2 phosphorylation was induced by sublethal PDT doses; increasing the photodynamic stress immediately led to apoptosis, during which Bcl-2 was neither phosphorylated nor degraded. The co-localisation of hypericin with α-tubulin and the aberrant mitotic spindles observed following sublethal PDT doses suggested that photodamage to the microtubule network provokes the G_2/M phase arrest. Bcl-2 phosphorylation is selectively suppressed by the cyclin-dependent protein kinase (CDK)-inhibitor roscovitine, completely blocked by the protein synthesis inhibitor cycloheximide and enhanced by the over-expression of CDK1, suggesting a role for this pathway [Vantieghem 2002].

The effect of an unspecified extract on antiproliferative activity of anticancer drugs and the expression of MDR1 mRNA were examined using HeLa and its MDR1-overexpressing subline. The effects on MDR1-mediated transport were evaluated using [^{3}H]-digoxin and MDR1 overexpressing LLC-GA5-COL150 cells. The effects of hypericin were compared with those of the extract. The extract (60 µg/mL containing 0.1 µM hypericin), but not hypericin, reversed the cytotoxicity of PXL and of daunorubicin slightly, down-regulated MDR1 mRNA, and inhibited MDR1-mediated transport [Wada 2002].

Hyperforin inhibited the growth of leukaemia K562 and U937 cells, brain glioblastoma cells LN229 and normal human astrocytes with GI_{50} values between 14.9 and 19.9 µM. Hyperforin and hypericin acted synergistically on leukaemic (K562, U937) cell growth. Cell death occurred by apoptosis after 24 h treatment with hyperforin. A dose-dependent loss of membrane phospholipid asymmetry associated with apoptosis was induced in all cell lines [Hostanska 2003b].

Different extracts (A: ethanol-water macerate of fresh flowering tops, B: macerate of flowering tops dried in the dark, C: aqueous-ethanolic percolation of the light-dried whole aerial parts), containing various amounts of hyperforin (A: 3.25%; B: 2.21%; C: 0.21% w/w) and flavonoids (A: and B: 5.3%; C: 10% w/w), but similar amounts of naphthodianthrones (0.3%), inhibited growth of K562 and U937 cell lines in the WST-1 assay. The GI_{50} for the extracts was 248.3-621.3 µg/mL in K562 and 378.2 911.7 µg/mL in U937 cells. The values of the three main constituents were 1.6 3.9 µM for naphthodianthrones, 1.0-40.7 µM for phloroglucinols and 30.5 68.5 µM for flavonoids [Hostanska 2003a].

The influence of a methanolic extract and hypericin on the human erythroleukaemic cell line K562 was tested. After 1 h exposure to increasing concentrations (as hypericin content: 0.5 to 5 µg/mL) of both agents in the dark, leukaemic cells were grown for 24 h and 48 h. Hypericin showed only a weak inhibitory effect on cell growth and no effect in inducing apoptosis. In contrast, the extract showed a significant ($p<0.05$) concentration-dependent inhibition of cell growth, and induced apoptosis [Roscetti 2004].

A lipophilic petroleum ether extract induced apoptosis with LC_{50} values of 5 and 7 µg/mL in T24 and NBT-II bladder cancer cells respectively. The most active fraction from this extract displayed 60% cell growth inhibition at a concentration of 0.95 µg/mL. Hyperforin concentrations in the extract and its most active fraction were 0.94 µg/mL, and 0.17 µg/mL respectively; considerably lower than the active cytotoxic concentration of pure hyperforin which appeared to be in the range of 1.8 µg/mL - 5.0 µg/mL [Skalkos 2005].

Hypericin inhibited protein kinase C in H-ras transfected mouse BALB 3T3 cells and induced apoptosis. This mechanism seemed to be linked to the photoactivated state, whereas in the dark no relevant cytotoxicity was observed [Kubin 2005; Lavie 1995; Takahashi 1989].

Hyperforin promoted apoptosis in B-CLL cells, as shown by time- and dose-dependent stimulation of phosphatidylserine externalisation and DNA fragmentation, by disruption of the mitochondrial transmembrane potential, caspase-3 activation and cleavage of the caspase substrate PARP-1 and induced down-regulation of the two antiapoptotic proteins Bcl-2 and Mcl-1. Hyperforin also down-regulated two proteins overexpressed by patients' B-CLL cells, the cell cycle inhibitor p27kip1 through

caspase-dependent cleavage into a p23 form, and the inducible NO synthase resulting in a reduction of NO production, known to be antiapoptotic in B-CLL cells. Preventing effects of the caspase inhibitor z-VAD-fmk indicated that hyperforin-promoted apoptosis of B-CLL cells was mostly caspase dependent. B lymphocytes from healthy donors appeared less sensitive to hyperforin-induced apoptosis than B-CLL cells [Quiney 2006].

Hyperforin-mediated induction of the mitochondrial pathway of caspase-dependent apoptosis was associated with up-regulation of Noxa, a BH3-only protein of the Bcl-2 family. Hyperforin was shown to induce an interaction between Noxa and a pro-survial protein Mcl-1, with the proapoptotic protein Bak becoming activated after being displaced from its complex with Mcl-1 [Zaher 2011]. These steps are known to cause mitochondrial membrane permeabilisation, accompanied by release of apoptogenic factors, and subsequent caspase cascade leading to apoptosis [Merhi 2011].

Hypericin induced an enhanced degradation of hypoxia-inducible factor 1α (HIF-1α) in two human tumour cell lines (U87-MG glioblastoma cells and RCC-C2VHL-/- renal cell carcinoma) and promoted ubiquitin ligation of HIF-1α mediated by lysosomal cathepsin-B enzymes through a hypericin-mediated reduction in intracellular pH [Barliya 2011].

The effect of hyperforin in the up-regulation of Noxa, a mitochondrial protein with pro-apoptotic activity, was investigated in cells from patients with chronic lymphocytic leukaemia CLL and the chronic B-cell leukaemia cell line MEC-1. Hyperforin caused an increase in Noxa expression in a time- and concentration-dependent manner. Noxa silencing by siRNA partially reduced hyperforin-elicited apoptosis [Zaher 2011].

The effects of hyperforin on acute myeloid leukaemia (AML) cell dysfunction were investigated in cell lines defining distinct AML subfamilies and primary AML cells. Hyperforin inhibited the growth of AML cell lines (U937, OCI-AML3, NB4, HL-60) by inducing apoptosis in a time- and concentration-dependent manner. It also induced apoptosis in primary AML blasts, whereas normal blood cells were not affected. The apoptotic process in U937 cells was accompanied by down-regulation of anti-apoptotic Bcl-2, upregulation of pro-apoptotic Noxa, mitochondrial membrane depolarisation, activation of procaspases and cleavage of the caspase substrate PARP 1. The caspase inhibitor Z-VAD-fmk and the caspase-9- and -3-specific inhibitors, but not caspase-8 inhibitor, significantly ($p<0.05$) attenuated apoptosis. Hyperforin-mediated apoptosis was associated with dephosphorylation of active Akt1 (at Ser(473)) and Akt1 substrate Bad (at Ser(136)) which activates Bad pro-apoptotic function. Hyperforin suppressed the kinase activity of Akt1, and combined treatment with the allosteric Akt1 inhibitor Akt-I-VIII significantly enhanced apoptosis of U937 cells [Merhi 2011].

A dried aqueous extract showed protective effects against oxidative DNA damage in HT29 colon cells (1 and 5 µg/mL). The extract and its main phenolic compounds quercetin and rutin (10 µM) resulted in a DNA protection of 40% ($p<0.05$). The alkylating damage repair was increased significantly ($p<0.05$) by 1 µg/mL extract (50%) and chlorogenic acid (80%) by base excision repair [Ramos 2013].

Anti-leukaemic effects of hyperforin were shown by induction of apoptosis in chronic lymphoid leukaemia (CLL) and acute myeloid leukaemia (AML) cells known for their resistance to chemotherapy. In AML cells, hyperforin inhibited the kinase activity of the serine/ threonine protein kinase B/AKT1, leading to activation of the pro-apoptotic Bcl-2 family protein Bad via non-phosphorylation by AKT1. In primary CLL cells, hyperforin acted by stimulating the expression of the pro-apoptotic Bcl-2 family member Noxa. Other hyperforin targets included matrix metalloproteinase-2 in AML cells and VEGF and matrix metalloproteinase-9 in CLL cells. Hyperforin also lowered the activity of Pgp which is involved in the resistance of leukaemia cells to chemotherapeutic agents [Billard 2013].

In this study hypericin was absorbed by melanoma cells and partially co-localised in the endoplasmic reticulum, mitochondria, lysosomes and melanosomes, but not the nucleus. Light activation of hypericin induced a rapid, extensive modification of the tubular mitochondrial network into a beaded appearance, loss of structural details of the endoplasmic reticulum and concomitant loss of hypericin co-localisation. The opposite was found for lysosomal-related organelles, suggesting that melanoma cells might use these intracellular organelles for hypericin-PDT resistance. However, hypericin-PDT was effective in killing both unpigmented (A375 and 501mel) and pigmented (UCT Mel-1) melanoma cells by specific mechanisms involving the externalisation of phosphatidylserines, cell shrinkage and loss of cell membrane integrity. The treatment resulted in extrinsic (A375) and intrinsic (UCT Mel-1) caspase-dependent apoptotic cell death, as well as a caspase-independent apoptotic mode that did not involve apoptosis-inducing factor (501 mel) [Kleemann 2014].

Antiangiogenic effects

Hyperforin blocked angiogenesis of human dermal microvascular endothelial cells (HDMEC) and reduced proliferation of HDMEC in a dose-dependent manner, without displaying toxic effects or inducing apoptosis [Schempp 2005].

In bovine aortic endothelial cells hyperforin treatment resulted in strong inhibitory effects on angiogenesis (IC_{50} 7 ± 3 µM). Capillary tube formation on Matrigel was abrogated completely by 2.5 µM hyperforin. Hyperforin also exhibited a clear inhibitory effect on the invasive capabilities of endothelial cells at 10 µM. Zymographic assays showed that hyperforin treatment produced a complete inhibition of urokinase and a remarkable inhibition of matrix metalloproteinase 2 [Martinez-Poveda 2005].

Hyperforin inhibited neutrophil and monocyte chemotaxis and angiogenesis induced by angiogenic chemokines (CXCL8 or CCL2) [Lorusso 2009].

Apoptosis

Pre-treatment with an unspecified extract significantly ($p<0.05$) decreased apoptosis in human SK-N-MC neuroblastoma cells as shown in different assays. In addition, pre-treatment with the extract inhibited H_2O_2-induced increase in caspase-3 activity [Jang 2002].

Antioxidant effects

Two extracts, standardised to either 0.3 – 0.5% hypericin or 3% hyperforin (not further specified), diluted between 1:1 to 1:20, were evaluated in a xanthine/xanthine oxidase assay in both cell-free and human vascular tissue. A pro-oxidant effect was seen at the highest concentration. Lower concentrations revealed dose-dependent antioxidant properties of the extracts with the strongest suppression at the most diluted concentration [Hunt 2001].

Strong antioxidant effects were observed for hyperforin in the oxidative burst of polymorphonuclear cells after stimulation with *N*-formyl-methionyl-leucyl-phenylalanine (IC_{50} 1.8 µM). No antioxidant activity was found after stimulation with opsonised zymosan or in the H_2O_2/ horseradish peroxidase system [Heilmann 2003].

Pre-incubation with an ethanolic extract for 24 h at 1-100 µg/mL significantly ($p<0.05$) prevented the marked reduction in cell survival observed following 8 h exposure of PC12 cells to H_2O_2 (300 µM). Different concentrations of the standardised extract (0.1-100 µg/mL) also attenuated the increase in caspase-3 activity and suppressed the H_2O_2–induced reactive oxygen species generation [Benedi 2004].

The free radical-scavenging properties of an ethanolic extract were studied using DPPH (EC_{50} = 49 µg dwb/mL), 2,2′-azobis (2-amidinopropane) dihydrochloride (AAPH) (EC_{50} = 50 µg dry weight biomass (dwb)/mL) and lipid peroxidation induced by ascorbate/iron (EC_{50} = 28 µg dwb/mL). The extract was able to scavenge NO and HOCl [Silva 2008b].

The antioxidant activity of an unspecified flavonoid-rich extract was investigated to demonstrate protection against hydrogen peroxide-induced apoptosis in PC12 cells. After exposure of PC12 cells to H_2O_2, a significant ($p<0.001$) decrease in cell viability and increased levels of lactate dehydrogenase (LDH) release were observed. Pre-treatment of PC12 cells with the extract elevated cell viability, decreased levels of LDH release, decreased occurrence of apoptotic cells and inhibited DNA laddering in PC12 cells [Zou 2010].

Pronounced antioxidant activity was observed for fractions of an extract in the DPPH assay (lowest IC_{50} 0.52 µg/mL), for NO scavenging (6.11 µg/mL), superoxide scavenging (1.86 µg/mL), lipid peroxidation (0.0079 µg/mL) and ferric reducing ability of plasma (highest reduction capacity 104 mg Fe^{2+} equivalents/g). The activity of the fractions was attributed to flavonoids and phenolic acids, while phloroglucinols and naphthodianthrones showed no significant activity [Orcic 2011].

The antioxidant activities of ethanolic, acetonic and petroleum ether extracts were determined in the DPPH assay. The IC_{50} values were <7.8, 105.9, 5.99 and 12.77 µg/mL for the ethanolic extract, the acetonic extract, and the two reference antioxidants, ascorbic acid and butylated hydroxytoluene (BHT), respectively. The petroleum ether extract did not demonstrate antioxidant activity [Mašković 2011].

An H_2DCFDA-assay was performed in porcine HaCaT keratinocytes irradiated with solar simulated radiation. Hyperforin (IC_{50} 0.7 µM) was much more effective than Trolox (IC_{50} 12 µg/mL) and *N* acetylcysteine (IC_{50} 847 µg/mL), without showing phototoxicity. The radical protection factor of a cream (containing 1.5% (m/m) hypericin-free CO_2 extract with 44.3% hyperforin) was 200×10^{14} radicals/mg, indicating a high radical scavenging activity. The cream *ex vivo* on porcine ear skin significantly ($p<0.05$) reduced radical formation after infrared irradiation [Meinke 2012].

An ethanolic (70%) extract was investigated for phototoxicity in A375 human melanoma cells. Linoleic acid peroxidation and DPPH tests were used to assess antioxidant activity, while the MTT assay allowed evaluation of anti-proliferative activity of A375 cells after irradiation with a UVA dose of 1.8 J/cm^2. Inhibition of NO production of macrophages was also investigated. The extract showed greater antioxidant activity in the beta-carotene bleaching test than in the DPPH assay (IC_{50} = 0.89 µg/mL); significant phototoxicity in A375 cells at 78 µg/mL concentration resulted in cell destruction of 50%. The extract caused significant ($p<0.05$) dose-related inhibition of NO production in murine monocytic macrophage cell line RAW 264.7 with an IC_{50} value of 342 µg/mL [Menichini 2013].

An unspecified ethanolic extract was assessed for its protective role on Ca^{2+} entry and oxidative stress through modulation of TRPM2 channels in dorsal root ganglion (DRG) neurons from male Wistar rats using whole-cell patch-clamp, Fura-2 and antioxidant experiments. TRPM2 current densities and $[Ca^{2+}]_i$ in the neurons were reduced by the extract at doses of 10, 20, 30 and 40 µg/mL (2 and 24 h after administration). Cytosolic Ca^{2+} mobilization was reduced by the extract and VGCC blockers (verapamil+diltiazem, V+D). Glutathione peroxidase activity and GSH values in the DRG were high for the extract, and lipid peroxidation was low [Naziroglu 2014a].

Penetration of blood-brain barrier

The penetration of [^{3}H]-amentoflavone through the blood-brain barrier (BBB) was studied in primary cell cultures of porcine brain capillary endothelial cells (PBCEC). The concentration-dependent uptake (37 2000 nM) was neither saturable nor temperature-sensitive, indicating passive diffusion as the major uptake mechanism as confirmed by transport experiments through PBCEC monolayers (> 2% of applied dose was transported after 30 min). Co-administration of an extract increased amentoflavone transport significantly (amentoflavone only: permeability coefficient P_{app} 4.59×10^{-6} cm/s; amentoflavone + extract: P_{app} 6.74×10^{-6} cm/s) indicating that the extract enhanced amentoflavone transport. In experiments with the Pgp over-expressing cell line P388-MDR, amentoflavone uptake was significantly enhanced by addition of the Pgp inhibitor verapamil [Gutmann 2002].

PBCEC were used as a model of the BBB and epithelial cells of the plexus chorioidei as a model of the blood-CSF barrier (BCB). Results indicated no active transport of miquelianin in one direction. Although moderate, the permeability coefficients (BBB: $Pc = 1.34 \pm 0.05 \times 10^{-6}$ cm/s; BCB: $Pc = 2.0 \pm 0.33 \times 10^{-6}$ cm/s) indicated the ability of miquelianin to cross both barriers to reach the CNS [Juergenliemk 2003].

The effects of a methanolic (80%) extract and selected constituents on the BBB transporter Pgp and on protein kinase C (PKC) were assessed in cultured PBCEC and freshly isolated pig brain capillaries from. Pgp function was studied in PBCEC using a calcein-AM uptake assay and in isolated pig brain capillaries using the fluorescent ciclosporin (CyA) derivative NBD-CSA and confocal microscopy. The extract (0.1 to 5 µg/mL) and the constituents hyperforin, hypericin and quercetin (0.1 to 10 µM) decreased Pgp transport activity in a dose- and time-dependent manner. The extract and hyperforin directly inhibited Pgp activity, whereas hypericin and quercetin modulated transporter function through a mechanism involving protein kinase C. Quercetin decreased Pgp transport activity at high concentrations, but increased transporter function at low concentrations [Ott 2010].

Effects on nitric oxide synthase

Quercetin and hyperoside showed concentration-dependent inhibitory activity on nitric oxide synthase (NOS) in blood and cerebral homogenate of rat. The IC_{50} values of quercetin in rat cerebral homogenate and blood were 63.06 and 57.54 µM, and those of hyperoside 56.23 and 158.49 µM, respectively [Luo 2004].

In vivo experiments

Biochemical findings

After acute and repeated oral treatment of mice with 10 mg/kg of an extract, the levels of serotonin and the serotonin metabolite 5-hydroxyindolacetic acid (5-HIAA) were increased in the hypothalamus and hippocampus indicating increased turnover; 5-HIAA levels were also increased in other regions of the brain [Yu 2000].

The effects of acute oral administration (24 h and 1 h before

testing) of a methanolic extract (62.5-500 mg/kg; 0.3% hypericin, 6% flavonoids) or an extract enriched in flavonoids (62.5-500 mg/kg; 0.3% hypericin, 50% flavonoids) on the levels of tryptophan, 5-HT, 5-HIAA, NE and DA in the cortex, diencephalon and brainstem of rats were evaluated. Results were compared with the effects of fluoxetine (10-80 mg/kg). The two extracts and fluoxetine increased 5-HT levels in the cortex. The flavonoid-enriched extract increased 5-HT and 5-HIAA levels in the diencephalon, and 5-HT and NE levels in the brainstem. Both extracts increased NE and DA levels in the diencephalon [Calapai 1999]. Comparable results for the flavonoid-enriched extract were obtained in a subsequent study using similar techniques; it did not modify tryptophan content, but significantly enhanced 5-HT and 5-HIAA levels in the cortex, diencephalon and brainstem at 125-500 mg/kg, and increased NE and DA in the diencephalon and NE in the brainstem at 250-500 mg/kg [Calapai 2001].

Rats were treated orally with 300 mg/kg of a hydromethanolic extract three times (23.5 h, 5 h and 1 h before forced swimming test). The extract significantly reduced immobility time ($p<0.01$). No significant changes in monoamine levels were detected in cortical or hippocampal brain regions 1 hour and 24 hours after the last dose [Calapai 2001].

The effects of imipramine (IMI; 15 mg/kg), an 80% methanolic extract (500 mg/kg) and hypericin (0.2 mg/kg) on the levels of 5-HT, NE, DA and their metabolites in the hypothalamus and hippocampus were investigated after short-term (2 weeks) and long-term (8 weeks) daily oral administration to rats. All three treatments significantly increased 5-HT levels in the hypothalamus ($p<0.05$) after 8 weeks, but not after 2 weeks; levels in the hippocampus were unchanged. 5-HT turnover (the ratio of 5-HIAA to 5-HT) was significantly reduced in both brain regions (both $p<0.05$) after 8 weeks of treatment with the extract but not with hypericin; IMI reduced 5-HT turnover only in the hippocampus. Consistent changes in catecholamine levels were only detected in hypothalamic tissues after long-term treatment. Comparable to IMI, the extract and hypericin significantly decreased 3,4-dihydroxyphenylacetic acid and homovanillic acid levels in the hypothalamus ($p<0.01$). The data showed that long-term, but not short-term, administration of St. John's wort and its active constituent hypericin modified levels of neurotransmitters in brain regions involved in the pathophysiology of depression [Butterweck 2002a].

The effects of acute and repeated administration of an undefined extract on extracellular levels of 5-HT, NE, DA, and their major acidic metabolites, in the brain of anaesthetised male Sprague Dawley rats were studied using *in vivo* microdialysis in the prefrontal cortex (PFC), ventral hippocampus and striatum. The extract inhibited the reuptake of DA, 5-HT and NE after i.p. administration of 60 mg/kg, whereas a single oral dose of 300 mg/kg only showed an effect on DA in the PFC. In rats treated for 14 days with a daily dose of 300 mg/kg p.o., the last dose of the extract increased the extracellular concentrations of all monoamines in the order DA >> 5-HT > NE, whereas the levels of metabolites were reduced in the order 3,4-dihydroxyphenylacetic acid << homovanillic acid < 5-hydroxyindoleacetic acid. The most pronounced effect of hypericum in both the acute and subchronic regimens was seen on the re-uptake and metabolism of DA [Kehr 2002].

The effects of a hydroalcoholic extract on extracellular 5-HT, NE and DA levels and the acidic metabolites (3,4-dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA) and 5-HIAA) were examined by *in vivo* microdialysis in the prefrontal cortex of awake rats. Single doses of the extract (60 mg/kg i.p. or 300 mg/kg p.o.) increased DA concentrations to 165 and 140% of control values respectively, and increased locomotor activity in non-habituated rats. DOPAC and HVA levels were markedly reduced. 5-HT concentrations were elevated moderately, while the NE levels were not affected by any treatment. Whole-tissue analysis revealed that the extract increased, whereas the MAO A/B inhibitor phenelzine decreased, DA and 5-HT turnover [Yoshitake 2004].

Neurotransmitter receptor density in the brain
Sprague-Dawley rats were treated daily for 26 weeks with an 80% methanolic extract (2700 mg/kg p.o.). In preparations of the brain without cerebellum and brain stem, the number of both 5-HT_{1A} and 5-HT_{2A} receptors were significantly ($p<0.01$) increased as compared to controls, whereas the affinity of both serotonergic receptors remained unaltered [Teufel-Mayer 1997].

Following sub-acute oral treatment of rats with 240 mg/kg of an 80% methanolic extract for 14 days, β-adrenoreceptor down-regulation was observed in the frontal cortex, a common characteristic finding for many antidepressant drugs. The simultaneous up-regulation of 5-HT_2 receptors observed was in contrast to the 5-HT_2 down-regulation observed with many classic antidepressants [Müller 1997].

Using the push-pull superfusion technique, neurotransmitter concentrations in the *locus coeruleus* of rats were studied after i.p. injection of hyperforin at 10 mg/kg. Extracellular concentrations of DA, NE, 5-HT and glutamate increased, whereas 5-HIAA, GABA, taurine, aspartate, serine and arginine remained unchanged [Kaehler 1999].

The short- (2 weeks) and long-term (8 weeks) effects of an 80% methanolic extract (500 mg/kg p.o.), a CO_2 extract (15 mg/kg p.o.), hypericin (0.2 mg/kg p.o.), hyperoside (0.6 mg/kg p.o.) and hyperforin-trimethoxybenzoate (8 mg/kg p.o.) on β-adrenoceptor (β-AR) binding were investigated by quantitative radioligand receptor-binding-studies in the frontal cortex of CD rats, and compared to IMI (15 mg/kg p.o.) and FLU (10 mg/kg p.o.). [^{125}I]-cyanopindolol binding to β-AR was decreased after short as well as long-term treatment with IMI (36%, $p<0.01$; 40%; $p<0.01$). Short-term treatment with FLU decreased the number of β-AR (17%; $p<0.05$) while it elicited an increase (14%; $p<0.01$) in β-AR-binding in long-term treatment. This effect was comparable to that of the CO_2 extract which decreased β-AR-binding (13%; $p<0.05$) after two weeks and slightly increased the number of β-AR's after 8 weeks (9%). Short-term treatment with the methanolic extract decreased β-AR-binding (14%); no effects were observed after 8 weeks. Treatment with hypericin led to a significant down-regulation (13%; $p<0.05$) of β-AR's in the frontal cortex after 8-weeks, but not after 2 weeks; hyperforin-trimethoxybenzoate and hyperoside were ineffective in both cases [Simbrey 2004].

Animal models of depression
Various test models of depression allow the detection of antidepressant activity. Behavioural experiments have indicated that St. John's wort extracts are centrally active, with a variety of extracts showing antidepressant-like properties in different animal models of depression. Antidepressant-like effects comparable in magnitude with those induced by classical antidepressants have been obtained in the rat forced swimming test (FST) and in related models, such as the mouse FST, the mouse tail suspension test (TST) and the rat learned helplessness test. The extracts also induced an antidepressant-like profile with respect to in vivo monitored field potentials in freely moving rats.

Forced swimming test
An 80% methanolic extract (0.24-0.32% total hypericin), at an oral dose of 125-1000 mg/kg b.w., significantly reduced

($p<0.05$ to $p<0.001$) the duration of immobility in the FST in male Sprague Dawley rats. The effects on immobility time were eliminated by dopamine D_2 antagonists [Winterhoff 1995].

A 50% ethanolic extract (250 mg/kg i.p.) was tested in mice in the FST, with DMI (30 mg/kg i.p.) and trimipramine (TRI) (20 mg/kg i.p.) serving as controls. All treatments significantly decreased swimming time of male albino mice ($p<0.05$) [Öztürk 1997; Öztürk 1996].

Fractionation of an 80% methanolic extract yielded two fractions with high activity in the FST with male CD rats, one contained mainly flavonoids and the other naphthodianthrones. Hypericin was inactive in the FST at a dose of 0.8 mg/kg. However, procyanidins (mainly procyanidin B_2) present in the naphthodianthrones fraction markedly increased the solubility and bioavailability of hypericin; in combination with procyanidin B_2 even 0.009 mg/kg p.o. hypericin was significantly active. Comparable results were obtained with pseudohypericin. In addition to hypericins, a flavonoid fraction from a methanolic extract and the flavonoids hyperoside, isoquercitrin and miquelianin showed significant activity in the FST after acute and sub-acute administration [Butterweck 2000; Butterweck 1998; Butterweck 1997].

The effect of oral administration of a CO_2 extract (38.8% hyperforin) was compared to an ethanolic extract (4.5% hyperforin) in the FST in rats [Chatterjee 1998a] and mice [Bhattacharya 1998]. Both extracts were active, with the effect of 5, 15 and 30 mg/kg of the CO_2 extract being comparable to that of 50, 150 or 300 mg/kg of the ethanolic extract.

Immobility time in the rat FST was significantly reduced by acute i.p. administration of 80% methanolic ($p<0.05$) and 50% ethanolic $p<0.01$) extracts. Results for these extracts (5-40 mg/kg) were comparable to i.p. administration of IMI (3-30 mg/kg) and FLU (3-30 mg/kg) [De Vry 1999].

Daily administration for 3 days of a 50% ethanolic extract, at 100 and 200 mg/kg p.o. to CF rats and Wistar mice, demonstrated comparable effects to acute administration of IMI at 15 mg/kg i.p. in various animal models of depression [Kumar 1999].

An extract (0.3% hypericin, 3.8% hyperforin) was administered intragastrically to male msP rats at 3 doses of 250 mg/kg. The anti-immobility effect of the extract in the FST was completely suppressed by i.p. pre-treatment with the σ-receptor antagonist rimcazole. Intracerebroventricular pre-treatment with 5,7-dihydroxytryptamine, which produced a marked depletion of brain 5-HT, also reduced the anti-immobility effect [Panocka 2000].

After acute oral administration to rats at 250-500 mg/kg, an unspecified extract enriched in flavonoids (0.3% hypericin, 4.5% hyperforin and 50% flavonoids) significantly and dose-dependently decreased immobility time ($p<0.001$ compared to saline). Concomitant treatment with the extract (500 mg/kg) and sulpiride (a DA receptor antagonist), metergoline (a serotonin receptor antagonist) or 6-hydroxydopamine (which destroys NE-containing neurons) significantly increased the period of immobility by 22-57%, the largest effect was observed with metergoline (57%; $p<0.001$) [Calapai 2001].

Several ethanolic (60%) and methanolic (80%) extracts demonstrated a significant ($p<0.01$) increase in activity in male Sprague-Dawley rats in the FST, with the exception of one methanolic extract containing a reduced level of rutin. Addition of rutin to this extract produced a pharmacological effect comparable to the other extracts [Nöldner 2002].

In the 24h preceding a FST, male CD-COBS rats were administered three i.p. injections of either one of two methanolic extracts (containing hyperforin at 4.5% (A) or 0.5% (B)), the dicyclohexylammonium (DCHA) salt of hyperforin or a vehicle. Immobilisation time was significantly decreased by extract A at doses of 3.12 and 6.25 mg/kg ($p<0.05$) and hyperforin DCHA at doses of 0.19 and 0.38 mg/kg ($p<0.01$), but not by extract B [Cervo 2002].

Three extracts were tested in the FST in male CD rats. Extract A (3.2% hyperforin, 0.15% hypericin) was prepared with 60% ethanol. Extract B (0.15% hypericin) was prepared from extract A by removal of hyperforin. Extract C (approximately 12% flavonoids) was prepared from extract B by removing naphthodianthrones. Immobility time was significantly reduced by oral administration of all three extracts (500 mg/kg) and IMI (30 mg/kg). Only extract C significantly reduced immobility time when the dose was reduced to 250 mg/kg. However, after 14 days of pre-treatment, similar effects were observed for all three extracts [Butterweck 2003a].

The effects of hyperoside at single i.p. doses of 7, 35 and 70 mg/kg was investigated in the FST in male BIC_{57} mice. With the increasing doses, immobility time increased by 10.1%, 25.8% and 38.6% respectively, as compared to controls [Bach-Rojecky 2004].

An ethanolic (60%; V/V) extract, rutin and isorhamnetin were compared to IMI in the FST after oral administration for 9 days. The extract and the two flavonoids were found to significantly decrease the duration of immobility, with isorhamnetin (3 and 10 mg/kg) exhibiting the strongest effect, more pronounced than after IMI administration. The administration of 200 mg/kg or more of the extract was comparable to 30 mg/kg IMI [Paulke 2008].

The effects of an ethanolic (A: 50%; (m/m), 0.08% hyperforin) and a methanolic (B: 80%; V/V, 4.5% hyperforin) extract were evaluated and compared to FLU (1 mg/kg p.o.) in male Wistar rats in the FST and an open field test over 28 days. The rats were given an oral daily dose of either one of four different doses of extracts A (1.78, 3.57, 7.14, and 14.28 mg/kg) or B (3.21, 6.43, 12.86, and 27.71 mg/kg), FLU or vehicle. The tests were carried out before treatment commenced and on days 7, 14, 21 and 28 of treatment. After 21 and 28 days of treatment, both extracts significantly ($p<0.05$) increased the latency to the first immobility and decreased the total immobility time in a dose-dependent manner. FLU significantly ($p<0.05$) increased the latency to first immobility and total immobility time. FLU exhibited antidepressant activity after 14 days, whereas with both extracts 21 days were required [Lozano-Hernandez 2010].

Adult male CF1 mice were treated with hyperoside (10, 20 or 40 mg/kg i.p.), IMI (20 mg/kg i.p.), or vehicle 30 min before the FST. Compared to vehicle, a significant ($p<0.001$) antidepressant-like effect was observed for hyperoside at doses of 10 and 20 mg/kg, comparable to IMI. In male Wistar rats, hyperoside (1.8 mg/kg/day p.o.) and IMI both showed a significantly (both $p<0.01$) decreased immobility time. The antidepressant-like effect in rats was prevented by the D_2 antagonist sulpiride (50 mg/kg i.p.) [Haas 2011; Schulte Haas 2011].

An unspecified extract at an oral dose of 25 mg/kg was compared to FLU (10 mg/kg i.p.) in male albino rats. Both treatments showed a significant ($p<0.05$) antidepressant effect in all behavioural studies and also significantly increased brain neurotransmitter levels, especially that of 5-HT. The effects of the extract were comparable to FLU [Kulkarni 2012].

The effects of a standardised extract (not further specified) at doses of 30-90 mg/kg i.p. were compared with standard

antidepressants in the FST when given 1 h before the test in male rats. The extract caused a dose-dependent reduction in immobility time with the maximal effect of 53% at 90 mg/kg ($p<0.001$). This effect was reversed at higher doses (100 mg/kg) showing a U-shaped dose response curve. FLU and IMI (30 -70 mg/kg i.p.) produced a similar reduction in the immobility time in rats, whereas VEN exhibited only a 34% reduction [Bukhari 2013].

Adhyperforin at an oral dose of 16 mg/kg significantly ($p<0.05$) decreased the immobility time of male Swiss mice [Tian 2014].

Escape deficit test (learned helplessness)
Male Charles Foster rats received either a CO_2 extract (no hypericin, no polyphenols, 38.8% hyperforin) or an ethanolic extract (0.3% hypericin, 4.5% hyperforin) before the inescapable electrical shock test. Control animals, trained to the inescapable shock situation, exhibited marked increases in escape failures under escapable conditions (72.5%), as compared to animals not previously trained to helplessness. Dose-dependent decreases of escape failures were observed for both extracts [Bhattacharya 1998; Chatterjee 1999].

Sprague-Dawley rats received 250, 500, 1000 or 1500 mg/kg of a hydroethanolic extract (0.3% hypericin) p.o., 60 minutes before an inescapable stress test. A significant dose-dependent reduction in escape deficit 24 h later was found for the 1000 mg ($p<0.05$) and 1500 mg ($p<0.01$) doses as compared to control. A tail-flick test and hot plate test confirmed that the result was not caused by a non-specific analgesic effect. Co-administration of the DA D_1 receptor antagonist SCH 23390 or the 5-HT_{1A}- and β-AR antagonist pindolol significantly reduced the efficacy of the extract. After pre-treatment of rats with daily doses of 500, 1000 or 2000 mg/kg p.o. for 15 days or IMI (5 mg/kg, i.p., twice daily), the extract at 1000 mg showed significantly ($p<0.05$) greater activity (increased escapes) than control, and the 2000 mg dose had a significant effect comparable with IMI ($p<0.01$) [Gambarana 1999].

Tail suspension test (TST)
A methanolic (80%, V/V) extract at an oral dose of 500 mg/kg caused a significant decrease in immobilisation time of NMRI mice. The effect was completely abolished by D,L butyrolactone (an inhibitor of dopaminergic neuron function), and by α-methyltyrosine (an inhibitor of DA and adrenaline synthesis) [Butterweck 1997].

Three different extracts were studied at an oral dose of 500 mg/kg in female NMRI mice: (A) an ethanolic (60%) extract (3.2% hyperforin, 0.15% of hypericin); (B) a CO_2 extract (no hyperforin, 0.14% hypericin) and (C) a sub-fraction of extract (B) (no hyperforin or hypericin, approximately 12% flavonoids). IMI (30 mg/kg p.o.) was used as control. Extracts B and C reduced immobility time significantly ($p<0.05$) and were comparable to IMI, whereas extract A was less active. Hyperforin produced a U-shaped dose-response curve: below 4 and above 8 mg/kg hyperforin remained inactive [Butterweck 2003a].

The effects of hyperoside at single oral doses of 7, 35 and 70 mg/kg were investigated in the TST in adult male CF1 mice. With the increasing doses, the antidepressant effect increased by 12.7%, 16.5% and 24.5% compared to controls [Bach-Rojecky 2004].

The administration of rutin (0.3 - 3 mg/kg, p.o.) reduced the immobility time of male Swiss mice in the TST without a change in locomotor activity. Pre-treatment of mice with p-chlorophenylalanine methyl ester (100 mg/kg, i.p., for 4 consecutive days) or alpha-methyl-p-tyrosine (100 mg/kg, i.p.), representing inhibitors of serotonin or NE synthesis respectively, prevented the effect of rutin in the TST [Machado 2008].

Hot plate
No activity of hyperoside (10, 20 and 40 mg/kg i.p.) was found on the hot-plate in male Swiss mice [Schulte Haas 2011].

Open field test (Locomotor activity)
Oral application for 3 days of a methanolic extract (80%, V/V; 500 mg/kg/day) or of hypericin (1.5 mg/kg/day) had no impact on the spontaneous motility of male and female CD rats [Winterhoff 1995].

The effect of an ethanolic (50%) extract on locomotor activity in the rota-rod test was assessed. Male albino mice received i.p. either the extract (250 mg/kg), DMI (30 mg/kg) or TRI (20 mg/kg). The extract demonstrated a significant decrease in the walking time of mice on the rotating rod ($p<0.05$). While DMI and TRI caused a more significant decrease ($p<0.005$) [Öztürk 1997; Öztürk 1996].

Oral doses of pseudohypericin (166 µg/kg) and hypericin (9 -28 µg/kg) were administered to male CD rats concomitantly with a fraction of flavonoids. The number of line crossings in comparison to the control group were not increased, suggesting that reported positive results in the FST (see above) were not related to stimulation of locomotor activity [Butterweck 1998].

Hyperoside, miquelianin and isoquercitrin at an oral dose of 0.6 mg/kg did not change locomotor activity in male CD rats [Butterweck 2000].

In contrast, a lyophilised aqueous infusion administered i.p. to male Charles River mice at doses of 25, 50, and 100 mg/kg significantly diminished the number of crossings and rearings ($p<0.01$), whereas immobility times were raised ($p<0.05$) [Coleta 2001].

A methanolic extract (80%, V/V; 500 mg/kg) or hypericin (0.1 mg/kg p.o.), administered alone or in combination with procyanidin B_2, did not induce changes in locomotor activity of male CD rats [Butterweck 2001a].

An unspecified methanolic extract was tested at doses from 2.5 to 200 mg i.p. in adult male CD1 mice. The extract increased motor activity at 10 mg/kg i.p. and decreased it at the highest dose [Diana 2007].

The effects of an ethanolic (50%) extract were tested on caffeine-induced locomotor activity in male Swiss-Webster mice. Caffeine (4 - 16 mg/kg i.p.) produced significant ($p<0.0001$) increases in locomotor activity. The extract (6 - 24 mg/kg i.p.) significantly ($p=0.016$) blocked the caffeine-induced locomotor hyperactivity. Pre-treatment with L arginine (1 g/kg) reversed the inhibitory effect of the extract (6 mg/kg i.p.) without any significant effect when administered alone [Uzbay 2007].

The effects of an ethanolic (50%) extract on behavioural changes were assessed in streptozotocin (STZ)-diabetic Wistar rats. In horizontal and vertical spontaneous locomotor activities, a diabetes mellitus-induced decrease was observed which was not restored by insulin (2 IU/kg/day). Treatment with the extract (125 and 250 mg/kg) for seven days resulted in a significant ($p<0.05$ and $p<0.01$) improvement [Can 2011b].

Adult male CF1 mice treated with single doses of hyperoside at 20 and 40 mg/kg i.p. showed reduced ($p<0.001$) exploratory behaviour in the open field test compared to controls [Schulte Haas 2011].

The effects of a standardised extract (details unknown) were compared with antidepressants in the open field test at doses of 1-30 mg/kg i.p. in rats. The extract caused a dose-dependent reduction in locomotor counts with a maximal effect of 80% at 30 mg/kg ($p<0.001$) compared to vehicle. FLU (30-70 mg/kg i.p.), dothiepin (30 mg/kg i.p.) and VEN (50 mg/kg i.p.) produced similar reductions in the number of locomoter counts (89%, $p<0.001$; 70%, $p<0.001$ and 62%, $p<0.001$, respectively) [Bukhari 2013].

Elevated plus maze
A CO_2 extract (no hypericin, 38.8% hyperforin) and an ethanolic extract (0.3% hypericin, 4.5% hyperforin) were tested in Wistar mice in the elevated plus maze (EPM). Both extracts at the highest dose (300 mg/kg) significantly ($p<0.05$) reduced the time spent in the open arm [Bhattacharya 1998].

Lyophilised aqueous extracts at i.p. doses of 25, 50 and 100 mg/kg were tested in the elevated plus maze in male Charles River mice. The extract significantly reduced ($p<0.01$) the total number of entries and the number of closed entries [Coleta 2001].

A diabetes mellitus-induced decrease in exploratory behaviour, indicating increased anxiety in STZ-diabetic Wistar rats, was not restored by daily insulin (2 IU/kg/day i.p.), but was significantly ($p<0.001$) improved by treatment with an ethanolic (50%) extract (125 and 250 mg/kg, i.p.) for seven days [Can 2011a].

Other pharmacological effects

Stress response
A 14-day mild, unpredictable and inescapable foot shock stress (FSS) test induced depression, suppressed male sexual behaviour, cognitive dysfunction, marked gastric ulceration and a significant increase in adrenal gland weight with concomitant decrease in spleen weight in albino rats. All these FSS-induced perturbations were attenuated dose-dependently by the extract at 100 and 200 mg/kg p.o. [Kumar 2001b].

Administration of a dried St. John´s wort preparation (350 mg/kg/day p.o.) for 21 days significantly enhanced recall of passive avoidance behaviour, but had no effect on the acquisition of conditioned avoidance responses in chronically (2 h daily for 21 days) stressed rats. Impaired recall of passive avoidance behaviour following chronic administration of corticosterone (5 mg/kg/day for 21 days) was also reversed [Trofimiuk 2006].

Male laca mice were sleep deprived for 72 hours using the grid suspended over water method. An ethanolic extract (60%; 0.3% hypericin, 4.1% hyperforin, 3.3% rutin, 1.8% hyperoside, 1.0% isoquercitrin, 1% quercetin, 0.3% bioapigenin) or IMI were administered for five days, starting two days before sleep deprivation. Sleep deprivation significantly altered body weight and locomotor activity, and produced anxiety-like behaviour and oxidative damage (depleted reduced GSH and CAT activity; increased lipid peroxidation and nitrite activity) as compared to naive animals placed on sawdust ($p<0.05$). Treatment with the extract (200 and 400 mg/kg p.o.) or with IMI (10 mg/kg i.p.) significantly improved body weight, locomotor activity, antianxiety and antioxidant effects as compared to the sleep deprived control ($p<0.05$). Co-administration of the extract (200 mg/kg p.o.) with IMI (10 mg/kg i.p.) further improved body weight, locomotor activity and the antianxiety effect, as well as reducing oxidative damage in sleep-deprived animals as compared to their effect *per se* ($p<0.05$) [Kumar 2007].

The effect of a methanolic (80%) extract on gastric mucosal damage induced by hypothermic restraint stress (HRS) was investigated in Wistar rats: group 1 was exposed to HRS, group 2 was the untreated control, groups 3-5 received the extract (25, 50 and 100 mg/kg/day p.o.), and group 6 received ranitidine (50 mg/kg s.c.) as the positive control. Macroscopic analysis of the stomach lesions showed that treatment with the extract at each dose significantly reduced lesions compared to stressed controls by 65, 95 and 75% respectively ($p=0.001$). Treatment with ranitidine also improved ulcers significantly. Histopathologic analyses indicated that 50 mg/kg/day of the extract produced the most significant effect [Cayci 2009].

In a restraint stress model, male Albino mice were immobilised for a period of 6 h resulting in severe anxiety like behaviour, antinociception and impaired locomotor activity as compared to unstressed animals ($p<0.05$). An unspecified extract was administered at doses of 50 and 100 mg/kg i.p. for five days 30 min before acute immobilised stress. Various behavioural parameters for anxiety, locomotor activity and nociceptive threshold were assessed, followed by biochemical assessments (malondialdehyde (MDA) level, GSH, catalase activity (CAT) and nitrite). Biochemical analyses revealed an increase in MDA and nitrites concentration, and depletion of reduced GSH and CAT, as compared to unstressed animal brain. Treatment with the extract significantly (all $p<0.05$) attenuated restraint stress-induced behavioural changes (improved locomotor activity, reduced tail flick latency and anxiolytic effect) and oxidative damage as compared to control [Kumar 2010].

An ethanolic (80%) extract was studied at doses of 125 to 750 mg/kg p.o. in a chronic restraint stress model. Stressed rats showed decreased time in open field activity compared to unstressed rats; an effect reversable by the extract and FLU (10 mg/kg p.o.). Chronic restraint stress significantly decreased thymus and spleen indices ($p<0.05$). The extract produced a significant and dose-dependent increase in both thymus and spleen indices compared to the stressed controls ($p<0.05$), as did FLU. Both treatments significantly reduced stress-induced increases in plasma ACTH and corticosterone levels ($p<0.05$ to $p<0.01$) as well as TNF-α levels ($p<0.05$) [Grundmann 2010].

Post-stress grooming
Post swim grooming behaviour of Wistar mice was significantly ($p<0.01$) increased by IMI (10 mg/kg i.p.), and dose-dependently and significantly ($p<0.05$ to <0.001) increased by oral administration of an ethanolic extract (0.3% hypericin, 4.5% hyperforin; 50-300 mg/kg/day), whereas a CO_2 extract (no hypericin, 38.8% hyperforin; 5-30 mg/kg/day) had a significant effect only at the highest dose ($p<0.05$) [Bhattacharya 1998].

Influence on body temperature
The decrease in body temperature after i.p. application of reserpine to female NMRI mice was counteracted by oral administration of a hydroalcoholic extract (0.015% hypericin) [Winterhoff 1993].

Oral treatment of male Charles Foster rats with either a CO_2 (no hypericin, 38.8% hyperforin) or an ethanolic (0.3% hypericin, 4.5% hyperforin) extract did not induce changes in body temperature, except for a slight increase at the highest dose of 300 mg/kg/day. Reserpine-induced hypothermia was completely antagonised by 15 mg/kg/day of the CO_2 extract and 300 mg/kg/day of the ethanolic extract. The activity of both extracts in reserpine-treated animals was similar to IMI (10 mg/kg i.p.) [Bhattacharya 1998].

A methanolic (80%; V/V) extract was administered orally to female NMRI mice (500 mg/kg). One hour after administration basal body temperature was significantly elevated ($p<0.005$) [Winterhoff 1995].

Exposure of male BL6/C57J mice to open field stress significantly increased body temperature by 1.8 ± 0.13°C ($p<0.05$). Oral administration of an ethanolic extract (80%; V/V; 0.3% hypericin, 4% hyperforin and 9.4% flavonoids) significantly reduced the body temperature increase at doses of 250 and 500 mg/kg ($p<0.01$). Hypericin (0.1 mg/kg p.o.) administered 60 min prior to testing significantly reduced the increase ($p<0.001$), whereas hyperforin (1 10 mg/kg p.o.) had no effect. Hyperoside, isoquercitrin and quercitrin (all at 0.6 mg/kg p.o.) and rutin (1 mg/kg p.o.) only partially blocked open field-induced hyperthermia ($p<0.05$). Miquelianin (1.2 mg/kg p.o., $p<0.05$) and amentoflavone (0.1 mg/kg p.o., $p<0.001$) also significantly decreased the stress-induced hyperthermia. Diazepam (5 mg/kg p.o; $p<0.001$) and the 5-HT_{1A} receptor agonist buspirone (10 mg/kg p.o.; $p<0.01$) significantly reduced the temperature increase, whereas IMI (10 mg/kg p.o.) and fluoxetine (10 mg/kg p.o.) had no effect [Grundmann 2006].

Influence on sleeping time
Oral pre-treatment of female NMRI mice with 500 mg/kg of an ethanolic extract (containing 0.015% hypericin), 2 h prior to injection of ketamine, significantly ($p<0.05$) reduced sleeping time [Winterhoff 1993].

Oral administration of a methanolic extract (80%, V/V; 50 to 1500 mg/kg) demonstrated dose-dependent activity in the same model, with fully expressed activity at 500 mg/kg ($p<0.001$). Dose reduction to 200 mg/kg led to a less pronounced reduction in sleeping time ($p<0.05$), while the effect with 50 mg was not significant. IMI (20 mg/kg) led to a prolongation of sleeping time, whereas bupropion (20 mg/kg), a dopamine re-uptake inhibitor, had the same effect as the extract. Hypericin, at doses equivalent to that found in the tested extract, exhibited less reduction in sleep duration when compared to the extract [Winterhoff 1995].

Effects on EEG
Power changes in the frontal cortex and hippocampus of male Fisher-344 rats were detected after oral administration of an ethanolic (50%, m/m) extract at doses of 0.5 and 1 mg. Frequencies in these brain areas changed predominantly in the direction of effects known from antidepressant drugs [Dimpfel 1997].

Continuous EEG was recorded in male rats after oral application of a CO_2 extract (30.1% hyperforin, practically no naphthodianthrones and flavonoids) and a methanolic extract (80%, V/V; 4.7% hyperforin). The dosage was adjusted for the application of identical amounts of hyperforin. Both extracts produced nearly identical patterns of electrical power changes during the first two hours. The changes mainly consisted of reproducible power increases within the α_1 band of the striatum, similar to the reaction following the application of SSRIs. The methanolic extract developed a late action (increased δ-activity) not seen with the CO_2 extract, which matched data obtained with NMDA-antagonists like MK 801 or memantine [Dimpfel 1998].

Effects on neurotransmitters and hormones
Three weeks of oral treatment with 125 mg/kg/day of a methanolic (80%, V/V) extract significantly reduced basal prolactin ($p<0.05$) and corticosterone levels ($p<0.01$) in male CD rats [Winterhoff 1995].

The effects of a methanolic extract (80%, V/V; 200 mg/kg i.p.), hypericin (0.4 mg/kg i.p.) and hyperforin (9.3 mg/kg i.p.) on 5-HT and DA-mediated neuroendocrine responses were measured in male Sprague-Dawley rats. Plasma corticosterone was significantly ($p<0.05$ to $p<0.001$) and equivalently increased in all three treatment groups. The effects were blocked by the 5-HT_2 receptor antagonist ketanserin, but not by the 5-HT_{1A} receptor antagonist WAY-100635. The effects were less pronounced after sub-chronic treatment with the extract (20 and 100 mg/kg/day for two weeks). Acute treatment with the extract and hyperforin significantly decreased plasma prolactin (PRL), whereas sub-chronic treatment with the extract at 100 mg/kg/day significantly ($p<0.01$) increased PRL [Franklin 2000; Franklin 2001].

Oral treatment of male Sprague-Dawley rats for 2 weeks with a methanolic (80%, V/V) extract (in a diet containing 3 g/kg) resulted in significantly reduced corticosterone ($p<0.002$) and PRL ($p<0.04$) responses to the post-synaptic 5-HT_{2A} receptor agonist 2,5-dimethoxy-4-iodophenyl-2-aminopropane [Franklin 2003].

Brain concentrations of corticosterone and cortisol (COR) were significantly reduced in rats receiving an oral dose of 3 g/kg of a methanolic (80%, V/V) extract for 2 weeks, whereas serum concentrations remained unaffected [Franklin 2004].

Using *in situ* hybridisation histochemistry, the effects of short-term (2 weeks) and long-term (8 weeks) oral administration of a CO_2 extract (containing about 23.7% hyperforin and 6.2% adhyperforin) and hyperforin-trimethoxybenzoate were studied in male CD rats. FLU and haloperidol were used as positive and negative controls respectively, to assess the expression of genes involved in the regulation of the hypothalamic-pituitary-adrenal (HPA). FLU (10 mg/kg p.o.) daily for 8 weeks, but not 2 weeks, significantly ($p<0.05$) decreased levels of CRH mRNA by 22% in the paraventricular nucleus of the hypothalamus and tyrosine hydroxylase (TH) mRNA by 23% in the locus coeruleus. FLU increased ($p<0.05$) levels of mineralocorticoid (MR) (17%), glucocorticoid (GR) (18%) and 5-HT_{1A} receptor (21%) mRNAs in the hippocampus at 8, but not 2, weeks. Comparable to haloperidol (1 mg/kg p.o.), neither the hyperforin-rich CO_2 extract (27 mg/kg p.o.) nor hyperforin-trimethoxybenzoate (8 mg/kg p.o.) altered mRNA levels in brain structures relevant for HPA axis control at either time point [Butterweck 2003c].

An ethanolic extract (DER 3.6:1; containing 0.13% hypericin and pseudohypericin, 3.03% hyperforin) was given orally at 20 to 240 mg/kg to male Sprague-Dawley rats over 8 weeks. Chronic IMI treatment (5 mg/kg/day i.p. for 8 weeks) significantly ($p<0.05$ both) down-regulated circulating plasma levels of adrenocorticotropic hormone (ACTH) and corticosterone compared to controls. The extract had no effect on plasma ACTH or corticosterone, even at the highest doses tested [Frost 2003].

Hypericin (0.2 mg/kg), hyperoside (0.6 mg/kg), isoquercitrin (0.6 mg/kg), miquelianin (0.6 mg/kg) and IMI (15 mg/kg), were administered daily to male CD rats by gavage for two weeks. The treatments significantly down-regulated circulating plasma levels of ACTH ($p<0.05$) and corticosterone ($p<0.05$ to $p<0.01$) by 40 - 70%. However, none of the compounds had an effect on plasma ACTH and corticosterone levels after chronic treatment over 8 weeks [Butterweck 2004].

In a study on the expression of genes involved in the regulation of the hypothalamic-pituitary-adrenal axis, short (2 weeks) and long term (8 weeks) oral administration to male CD rats of a methanolic extract (80%, V/V; 500 mg/kg), hypericin 0.2 mg/kg) and IMI (15 mg/kg) resulted in decreased levels of mRNA for CRH ($p<0.01$) by 16 - 22% in the paraventricular nucleus, and mRNA for 5-HT_{1A}-receptor ($p<0.05$ to $p<0.01$) by 11 - 17% in the hippocampus. Only IMI decreased tyrosine hydroxylase mRNA levels in the *locus coeruleus* by 23% ($p<0.01$) after 8 weeks [Butterweck 2001b].

An ethanolic extract (0.3% hypericin, 4.5% hyperforin), but not a CO_2 extract (no hypericin, 38.8% hyperforin), dose-

dependently and significantly ($p<0.001$) potentiated L-DOPA-induced changes in behaviour of Wistar mice. Treatment with apomorphine (0.5 mg/kg i.p.) led to stereotypical behavioural changes which were increased by IMI (10 mg/kg i.p.) ($p<0.01$). The ethanolic extract, and to a lesser extent the highest dose of the CO_2 extract, significantly ($p<0.001$ and $p<0.05$ respectively) increased the apomorphine stereotypy score [Bhattacharya 1998].

The effects of a methanolic extract (80%, V/V; 4.67% hyperforin; 31.25, 62.5 and 125 mg/kg/day) and a CO_2 extract (30.14% hyperforin; 2.42, 4.84 and 9.68 mg/kg/day) were investigated in male CD rats as single oral doses acutely and over 14 days. IMI (20 mg/kg/day p.o.) and vehicle served as controls. Both extracts increased DA and 5-HT levels, as measured by *in vivo* microdialysis. The dose-response curve followed an inverse U-shape. Repeated administration caused a rapid tolerance of DA but not of 5-HT neurons. Similar changes were observed after acute and repeated administrations of IMI. The potency of hyperforin surpassed that of imipramine in the acute release of both DA and 5-HT by the nucleus accumbens. The effect of hyperforin correlated with its inhibiting potency on high-affinity DA and 5-HT uptake. The inhibition of neuronal GABA transport occurred at higher concentrations of hyperforin [Rommelspacher 2001].

The effect of hyperforin on striatal ACh release and associated choline levels was studied using microdialysis in adult Sprague-Dawley rats. Local infusion of hyperforin (10 µM and 100 µM) via the dialysis probe caused changes in brain ACh and choline levels. Systemic administration of hyperforin (1-10 mg/kg i.p.) led to therapeutic plasma levels of hyperforin and caused a significant elevation of striatal ACh release. The higher hyperforin dose (10 mg/kg) revealed a reduction of locomotor activity in CD1 mice [Buchholzer 2002].

Male rats were treated orally with two different doses (30 and 100 mg/kg) of an unspecified extract for 3 or 15 days. A 3-day treatment was not able to modify PRL serum levels, whereas a 15-day treatment with the extract at the higher dose significantly ($p<0.01$) inhibited PRL production [Di Carlo 2005].

The effects of chronic treatment with intragastric injections of a methanolic (80%V/V) extract on neurochemical markers of 5-HT, DA and opioid systems in mesolimbic regions of fawn-hooded male FH rats were investigated by quantitative autoradiography. After 10 days' treatment, the extract increased [^{3}H]-citalopram binding to 5-HT transporters in multiple mesolimbic regions. In contrast, the extract resulted in a region-specific alteration of [^{3}H]-mazindol binding to DA transporters, such as increased binding of [^{3}H]-mazindol in the olfactory tubercle and decreased binding in the ventral tegmental area. In addition, the extract resulted in differential modulation of the binding properties of 5-HT_{1A}-, 5-HT_{2A}- and µ-opioid receptors in a region-specific manner [Chen 2003].

Cognitive effects

The effect of a 50% ethanolic extract was investigated in various experimental models of learning and memory, *viz*. transfer latency (TL) on elevated plus-maze, passive avoidance (PA), active avoidance (AA), and scopolamine- and sodium nitrite-induced amnesia (SIA & NIA) in albino rats. The extract was administered orally (100 and 200 mg/kg) for three days, while piracetam (500 mg/kg i.p.), a nootropic agent, was administered acutely. The extract and piracetam significantly ($p<0.01$) shortened TL on days 2 and 9, and antagonised the amnesic effects of scopolamine and sodium nitrite on TL. The extract had no significant effect on the retention of PA. The higher dose produced a significant ($p<0.05$) reversal of scopolamine-induced PA retention deficit but no significant reversal was observed with sodium nitrite. The extract at both doses and piracetam facilitated the acquisition and retention of AA and attenuated the scopolamine and sodium nitrite-induced impaired retention of AA [Kumar 2000].

The effect of an ethanolic (80%, V/V) extract was tested on memory retrieval 24 h after training on a one-trial passive avoidance task in male Swiss albino mice. Acute i.p. administration at doses of 4.0, 8.0, 12.0, and 25.0 mg/kg before retrieval testing increased ($p<0.01$) the step-down latency during the test session. The same doses of the extract failed to reverse scopolamine-induced amnesia of a two-trial passive avoidance task. Pre-treatment of the animals with serotonergic 5-HT_{1A} receptor antagonist (-)-pindolol (0.3, 1.0, and 3.0 mg/kg s.c.), serotonergic 5-HT_{2A} receptor blocker spiperone (0.01, 0.03, and 0.1 mg/kg i.p.), α-AR antagonist phentolamine (1, 5, and 10 mg/kg i.p.), β-AR antagonist propranolol (5, 7.5, and 10 mg/kg i.p.), dopaminergic D_1 receptor antagonist SCH 23390 (0.01, 0.05, and 0.1 mg/kg i.p.), and dopaminergic D_2 receptor antagonist sulpiride (5, 7.5, and 10 mg/kg i.p.) revealed the involvement of adrenergic and serotonergic 5-HT_{1A} receptors in the facilitatory effect of the extract on retrieval memory [Khalifa 2001].

The effects of a methanolic (80%, V/V) extract and hyperforin sodium salt were evaluated in rat and mouse avoidance tests. In a conditioned rat avoidance response, 7 days oral administration of the extract (50 mg/kg/day) and hyperforin (1.25 mg/kg/day) improved learning ability from the second day until day 7. The memory of the learned responses acquired during the 7 consecutive days of administration and training was largely retained after 9 days without further treatment or training. A single dose of the extract at 25 mg/kg did not reveal any significant effects in the passive avoidance response test in mice, whereas a single oral dose (1.25 mg/kg) of hyperforin almost completely reversed scopolamine-induced amnesia [Klusa 2001].

The Morris water maze (MWM) was used to test the effects of St. John's wort tablets containing dried crude herb standardised to 0.3% hypericin, administered orally for 9 weeks at doses equivalent to 4.3 and 13 µg/kg hypericin to male Wistar rats. In the acquisition phase (days 1 to 4) latencies were significantly ($p<0.001$) reduced due to training. The learning effect was greater ($p<0.05$) in the high dose group than in the low dose group or control. In the probe trial on day 5, the high dose group crossed the correct annulus in the target quadrant significantly ($p<0.05$) more often than the other groups. After completion of the experiment, the concentrations of monoamines and metabolites were determined in selected brain regions (prefrontal cortex, hippocampus and hypothalamus) demonstrating significant ($p<0.05$ to $p<0.001$) differences in their contents between the treatment groups and control [Widy-Tyszkiewicz 2002].

Hippocampal acetylcholine levels were increased ($p<0.01$ to $p<0.001$) by 50-100% in adult Sprague-Dawley rats after i.p. administration of hyperforin at doses of 1 and 10 mg/kg. The effect was almost completely suppressed by local perfusion with calcium-free buffer or with tetrodotoxin (1 µM) [Kiewert 2004].

The potential for prevention of working memory impairments was tested in male Wistar rats orally administered 350 mg/kg of an extract (solvent not specified; 0.05-0.3% hypericin, 2-4.5% hyperforin, 2-4% flavonoids and 8-12% procyanidins) for 21 days. Spatial working memory impairments caused by chronic restraint stress or medication with exogenous corticosterone in the Barnes maze and MWM were prevented ($p<0.001$). The treatment significantly improved hippocampus-dependent spatial working memory in comparison with control ($p<0.01$) and alleviated other negative effects of stress on cognitive functions [Trofimiuk 2008; Trofimiuk 2005].

Middle-aged male Wistar rats (18 months) displayed a decline in the acquisition of spatial working memory in the MWM. Chronic oral administration of the same extract (350 mg/kg for 21 days) significantly ($p<0.001$) improved processing of spatial information and increased the levels of phosphorylated cAMP response element binding protein in the hippocampus ($p<0.01$). Locomotor impairments caused by ageing as tested in the OFT remained unaffected [Trofimiuk 2010].

An ethanolic (50%) extract significantly improved glucose metabolism in STZ-induced diabetic Wistar rats when given at i.p. doses of 125 and 250 mg/kg over one week and significantly improved learning parameters of animals in a shuttle-box test ($p<0.01$ to $p<0.001$) compared to controls [Can 2011a].

The effect of an aqueous dry extract (3% (m/m) hyperforin and > 20% (m/m) flavonoids) on diabetes-induced learning and memory impairment was assessed in streptozotocin-induced diabetic rats. After oral administration of 6, 12 and 25 mg/kg for 30 days, passive avoidance learning and memory were significantly ($p<0.05$ to $p<0.001$) improved by the two highest doses [Hasanein 2011].

The potential for alleviation of stress- and corticosterone-related memory impairments by restoring levels of the synaptic plasticity proteins, neuromoduline (GAP-43) and synaptophysin (SYP), in hippocampus and prefrontal cortex was tested in male Wistar rats which displayed a decline in the acquisition of spatial working memory in the Barnes maze. Chronic oral administration of a dried St. John's wort preparation (350 mg/kg for 21 days) potently improved processing of spatial information in stressed and corticosterone-treated rats ($p<0.001$). Treatment significantly increased levels of GAP-43 and SYP in hippocampus and prefrontal cortex ($p<0.05$) and prevented the deleterious effects of both chronic restraint stress and prolonged corticosterone administration on working memory. It significantly ($p<0.01$) improved hippocampus-dependent spatial working memory in comparison with control and alleviated other negative effects of stress on cognitive functions [Trofimiuk 2011].

The effect of an ethanolic extract (80%; 250 and 500 mg/kg p.o.) and FLU (10 mg/kg p.o.) on genes involved in the pathogenesis of depression were studied using a chronic restraint stress model in rats. Hypothalamic and hippocampal tissues were analysed using the Affymetrix gene chip Rat Genome 230 2.0 Array. Genes involved in the pathways of inflammatory processes (Mapk8), oxidative stress (Gpx3, Gstm3, Sod3) and Alzheimer's disease (Sncb, Apbb1ip) were altered by both FLU and the extract [Jungke 2011].

Anxiety
A methanolic (80%, V/V) extract was given to male Wistar rats at doses of 62.5-500 mg/kg p.o., either acutely or as chronic treatment for 14 days. The animals were tested in the elevated T-maze (ETM), the light/dark transition, and the cat odour test. The results showed that acute treatment (125 mg/kg) impaired ETM inhibitory avoidance without altering escape performance. Chronic treatment (62.5-250 mg/kg) enhanced avoidance latencies only in animals pre-exposed to the open arms of the maze, with pre-exposure shortening escape latency. In contrast to IMI (15 mg/kg p.o.), chronic treatment with the extract did not impair escape from the open arms of the maze. Similarly to IMI, the extract increased the number of transitions between the two compartments in the light/dark transition model. Treatment regimens with the extract and IMI did not alter behavioural responses of rats to a cloth impregnated with cat odour [Flausino 2002].

A methanolic extract (80%, V/V; 0.3% hypericin, 3.3% hyperforin) was administered orally at doses of 150 and 300 mg/kg acutely, subchronically (7 days) and chronically (21 days) to adult male Swiss albino mice. PAR at 5 mg/kg was used as a positive control. Anxiolytic-like and antipanic-like effects were assessed with the mouse defence test battery. On day 21 both treatments showed reduced flight reactions to the presence of the predator. After 21 days PAR increased the number of approaches/withdrawals and reduced the number of upright postures, while the extract only reduced the number of upright postures [Beijamini 2003].

A hydroalcoholic extract (not further specified) was tested for the treatment of co-morbid mood disturbances and anxiety in diabetic rats. Type 2 diabetes mellitus was induced by a single i.p. injection of STZ (65 mg/kg), 15 min after an i.p. injection of nicotinamide (120 mg/kg). The extract was administered orally (100 and 200 mg/kg) to diabetic animals for 14 days. Anxiolytic activity was evaluated using the open-field exploration test (OFT) and elevated plus maze (EPM) test. Diabetic rats showed a significant increase in anxiety in OFT ($p<0.05$) and EPM ($p<0.05$) compared to non-diabetic control rats. Treatment with the extract significantly ($p<0.001$) improved anxiety symptoms in the OFT and ($p<0.001$) reduced elevated blood glucose levels in diabetic rats [Husain 2011a].

Neuroprotection
In male Sprague-Dawley rats hyperforin (6 μM) injected in the hippocampus bilaterally (i) decreased Aβ deposit formation after injection of amyloid fibrils in the hippocampus, (ii) decreased the neuropathological changes and behavioural impairments in a model of amyloidosis, and (iii) prevented Aβ-induced neurotoxicity in hippocampal neurons both from amyloid fibrils and Aβ oligomers, avoiding the increase in ROS associated with amyloid toxicity. The effects were explained by the capacity of hyperforin to disaggregate amyloid deposits in a dose and time-dependent manner and to decrease Aβ aggregation and amyloid formation [Dinamarca 2006].

The effect of an unspecified extract (0.34% hypericin, 4.1% hyperforin, 5% flavonoids, 10% tannins) given at an oral dose of 30 mg/kg was evaluated in an experimental model of spinal cord injury in adult CD1 mice. The degree of (a) spinal cord inflammation and tissue injury (histological score), (b) nitrotyrosine, (c) poly(adenosine diphosphate-ribose), (d) neutrophils infiltration, and (e) the activation of signal transducer and activator transcription 3 were markedly reduced in spinal cord tissue [Genovese 2006b].

Wistar rats (18 months old) displayed a decline in the acquisition of spatial working memory ($p<0.001$) in the MWM. Administration of a dried St. John´s wort preparation (0.3 % hypericins, 6% hyperforin, 2-4% flavonoids and 8-12% procyanidins), at an oral dose of 350 mg/kg for 21 days, significantly improved the processing of spatial information ($p<0.001$). The preparation also increased pCREB in the hippocampus ($p<0.01$). Aging caused significant locomotor impairments in the OFT ($p<0.001$) but no changes in the MWM test; factors unaffected by the treatment [Trofimiuk 2010].

Neurogenesis
A methanolic extract was administered at an i.p. dose of 30 mg/kg/day for 3 weeks to adult CD1 mice with corticosterone-induced stress. Treatment with the extract reversed the decrease in hippocampal progenitor cell proliferation induced by corticosterone. Stressed mice also exhibited a reduced dendritic spine density that was significantly ($p<0.05$) ameliorated by the extract [Crupi 2011].

Alzheimer's disease
Quercetin and kaempferol stimulated depression-related

signalling pathways involving brain-derived neurotrophic factor (BDNF), phosphorylation of cAMP response element binding protein CREB and postsynaptic density proteins PSD95, and reduced Aβ peptide in neurons isolated from double transgenic AD mice (TgAPPswe/PS1e9). Administration of the flavonols enhanced BDNF expression and reduced Aβ oligomers in hippocampus of the mice; this correlated with cognitive improvement [Hou 2010].

A methanolic extract (80%, V/V; 5% hyperforin) was given orally (1250 mg/kg/day) to 30-day-old male C57BL/6J-APP/PS1(+/-) mice for 60 or 120 days. When compared to the untreated controls, mice receiving the extract showed significant ($p<0.05$ to $p<0.01$) reductions in plaque load for both $A\beta_{1-40}$ and $A\beta_{1-42}$, and significant ($p<0.001$ to 0.0001) increases in cerebrovascular Pgp expression [Brenn 2014].

Parkinson's disease
A study evaluated the protective effect of chronic administration of two standardised extracts, (A) rich in hyperforin (6%) and (B) poor in hyperforin (0.2%), and quercetin, against neurodegeneration induced by chronic administration of rotenone in rats.The animals received pre-treatment with extract A (4 mg/kg i.p.), extract B (4 mg/kg i.p.) or quercetin liposomes (25 and 100 mg/kg i.p.) 60 min before rotenone injection (2.5 mg/kg) for 45 days. Pre-treatment with both extracts efficiently blocked deleterious toxic effects of rotenone, revealing normalisation of catalepsy and amelioration of neurochemical parameters. Extract A also reduced neuronal damage by diminishing the substantia nigra dopaminergic cell death caused by rotenone and inhibited the apoptotic cascade by decreasing Bax levels. Extract A was more active than extract B [Gomez del Rio 2013].

Movement disorders
The effects in male Wistar rats of an unspecified aqueous extract (300 mg/kg/day p.o.) were evaluated in models of abnormal movements induced by fluphenazine (25 mg/kg/day i.m.) or reserpine (0.5 mg/kg, s.c. every 2 days for 6 days). The number of vacuous chewing movements (VCMs) and locomotor activity were measured. In experiment 1, rats received a single dose of fluphenazine enanthate and/or the extract for 7 days. In experiment 2, rats received reserpine and/or the extract for 16 days beginning 10 days before the first administration of reserpine. The extract failed to protect against orofacial movements induced by fluphenazine or reserpine [Reis 2013].

An ethanolic (70%) extract was tested in a rat model of Parkinson's Disease. Unilateral intrastriatal lesions were induced by 6-hydroxydopamine (6-OHDA) in adult male Wistar rats. Treatment with the extract (200 mg/kg/day i.p.) was started 1 week pre-surgery and continued for 1 week post-surgery. The extract attenuated apomorphine-induced rotational behaviour, decreased the latency to initiate and the total time in the narrow beam task, lowered striatal level of malondialdehyde, enhanced striatal catalase activity and reduced GSH content, normalised striatal expression of glial fibrillary acidic protein and tumour necrosis factor alpha with no significant effect on mitogen-activated protein kinase, lowered nigral DNA fragmentation, and prevented damage of nigral dopaminergic neurons with a higher striatal tyrosine hydroxylase immunoreactivity [Kiasalari 2015].

Effects on seizures
The effects of different fractions of an ethanolic (80%) extract (A: water, B: ether, C: *n*-butanol; at 100 mg/mL i.m.) on the kindling epileptic discharges in Chinchilla rabbits were analysed using electrodes implanted in cortical structures and hippocampus. The effect correlated with the polarity of the fractions. The most polar constituents found in the water fraction exerted the highest antiepileptic activity in 100% of animals. The butanol fraction repressed the epileptic manifestations in 40% of animals, whereas lipid-soluble constituents in the ether fraction potentiated the epileptic activity [Ivetic 2002].

The anticonvulsant activity of undefined aqueous and ethanolic extracts was studied in mice in the pentylenetetrazole (PTZ) and the maximal electroshock seizures (MES) tests. In the PTZ test, the extracts (0.1-1 g/kg i.p.) delayed the onset of tonic convulsions and protected mice against mortality. In the MES test, neither extract demonstrated anti-seizure activity. L-NAME (1-10 mg/kg i.p.) reduced the anticonvulsant activity of the extracts [Hosseinzadeh 2005].

Water, *n*-butanol and ether fractions of an ethanolic (70%) extract were tested on epileptogenesis in Chinchilla rabbits of both sexes in the kindling model of epilepsy. Epileptic focus was induced by stimulation of the hippocampus. Animals treated with the ether fraction required significantly weaker minimum current strengths for development of epileptogenic focus, and displayed longer after-discharge (AD) times, while the number of electro-stimulations necessary for full kindling was less. In contrast, animals treated with water and n-butanol fractions required increased electro-stimulations for the development of epileptic discharge, and displayed shortened AD durations versus controls [Ivetic 2011].

A methanolic (80%) extract was given at doses of 25 to 200 mg/kg i.p. to male adult mice. After 20 min, seizures were induced by 10 mg/kg i.p. picrotoxin. Latency to seizure increased with the extract at 50 mg/kg ($p<0.01$). The highest dose (200 mg/kg) significantly decreased duration of seizure ($p<0.01$) and death latency ($p<0.01$) [Etemad 2011].

The effect of a standardised extract (not futher specified) on PTZ-induced convulsions was compared with standard antidepressants (FLU 30 and 50 mg/kg i.p.; dothiepin 30 and 50 mg/kg i.p.; VEN 30 mg/kg i.p.). Male mice were injected with either saline, the extract (50-500 mg i.p.) or the antidepressants. Sixty minutes later, animals received 60 mg/kg i.p. pentylenetetrazole. In a dose-dependent manner, the extract significantly ($p<0.05$ to $p<0.001$) reduced latency to convulsion, with the maximum reduction of about 43% at 100 and 200 mg/kg. The extract also dose-dependently increased mouse mortality, with 100% mortality occurring at 400 mg/kg. FLU, dothiepin and VEN at 30 mg/kg produced maximum reductions in latency of 33, 44 and 37.6% respectively. VEN caused 80% mortality at 30 mg/kg, while at the same dose FLU and dothiepin caused 20 and 40% mortality respectively [Bukhari 2013].

Migraine
The pain-relieving property of an unspecified extract was measured in male Swiss albino mice. The NO donors nitroglycerin (GTN; 10 mg/kg i.p.) and sodium nitroprusside (SNP; 0.5, 1 and 2 mg/kg i.p.) induced allodynia (cold plate test) and hyperalgesia (hot plate test). A single oral dose of the extract (5 mg/kg p.o.) produced a prolonged relief from pain hypersensitivity. Pre-treatment with the extract delayed the onset of hyperalgesia and reduced the duration of the painful symptomatology. No behavioural side effects or altered locomotor activity were observed [Galeotti 2013a].

An unspecified extract (5 mg/kg p.o.) reduced meningeal nociception in mice induced by GTN and SNP, which produced a delayed meningeal inflammation, as shown by the upregulation of IL-1β and iNOS, and a prolonged cold allodynia and heat hyperalgesia with a time-course consistent with NO-induced migraine attacks. A single oral administration of the extract counteracted the nociceptive behaviour and the

over-expression of IL-1β and iNOS. The increased expression and phosphorylation of pro-inflammatory factors was prevented by the extract and hypericin (10 µg/kg p.o.) [Galeotti 2013b].

Antinociceptive effects
The i.p. administration of 30-100 mg/kg of an unspecified extract produced significant analgesic effects in acetic acid-induced writhing (up to 88% inhibition, $p<0.001$) and formalin licking tests (up to 83% inhibition, $p<0.01$) in NMRI mice. The effect was twice as potent as ibuprofen (100 mg/kg i.p.) in the acetic acid-induced writhing test [Bukhari 2004].

Oral administration of an unspecified extract (25 mg/kg) displayed antinociceptive activity in the tail electric stimulation ($p<0.05$) and hot plate ($p<0.01$) tests. Acetic acid-induced writhing was significantly ($p<0.05$) reduced by oral FLU (50 mg/kg) or etodolac (72 mg/kg), but not by the extract. The nociceptive response caused by i.p. injection of capsaicin (1.6 µg/paw) was unaffected by the extract, but reduced by FLU ($p<0.05$). Injection of the extract (50, 125 or 250 mg/kg s.c.) to pylorus-ligated rats decreased gastric acid secretion, but increased indomethacin-induced gastric mucosal lesions dose-dependently [Abdel-Salam 2005].

An unspecified hydroethanolic extract was studied in acetic acid-induced abdominal constriction in Balb-C mice. The extract (10-20 mg/kg i.p.), opium (10-30 mg/kg i.p.), morphine (0.75-3.0 mg/kg i.p.) and acetylsalicylic acid (50-100 mg/kg i.p.) showed dose-dependent antinociceptive effects. In animals treated with naloxone (0.5 mg/kg s.c.), the antinociceptive effect of the extract was significantly ($p<0.05$ to $p<0.01$) reduced similar to that of opium, while the effect of acetylsalicylic acid remained unchanged [Subhan 2007].

A study investigated the antinociceptive properties of an unspecified extract in male ICR mice. Oral pre-treatment with the extract (100 1000 mg/kg) significantly ($p<0.05$) attenuated licking/biting times, in both the first and second phases following formalin injection in a dose-dependent manner. Naloxone (5 mg/kg s.c.) did not attenuate the effect. Formalin injection resulted in an increase in nitrites/nitrates (NOx) in mouse spinal cord which was significantly ($p<0.05$) attenuated by the extract. Pre-treatment with the extract significantly ($p<0.01$) potentiated the antinociceptive effect of morphine (0.3 mg/kg s.c.), although concentrations of morphine in plasma and brain were not significantly changed [Uchida 2008].

An unspecified dried extract induced a prolonged antinociceptive effect for 120 minutes after intracerebroventricular (i.c.v.) injection to male Swiss albino mice in acute thermal and chemical pain. Thermal antinociception was prevented by naloxone and by the protein kinase C (PKC) activator PMA, whereas the chemical antinociception was prevented only by PMA. A chloroform (CHL) and a methanol (MET) fraction increased pain threshold with a time course comparable to the extract. The CHL antinociception was antagonised by naloxone, the MET antinociception by PMA. Hyperforin and hypericin showed an antinociceptive efficacy comparable to CHL and MET respectively. The flavonoids remained without effect. The presence of hypericin was fundamental to inducing thermal and chemical antinociception through the inhibition of the PKC activity, whereas hyperforin selectively produced a thermal opioid antinociception [Galeotti 2010a].

Neuropathic pain
An unspecified dried chloroform extract was investigated for its effect on neuropathic pain due to chronic constriction injury or the repeated administration of oxaliplatin (3.4 mg/kg i.p.) in male Sprague Dawley albino rats. Acute administration of the extract at low doses (30 60 mg/kg p.o.) reversed mechanical hyperalgesia up to 180 min after administration. Hyperforin and hypericin were responsible for the antihyperalgesic properties whereas flavonoids were ineffective. Treatment with the extract, hyperforin and hypericin did not result in any behavioural side effects or signs of altered locomotor activity [Galeotti 2010b].

The antinociceptive effect of an unspecified extract on hypersensitivity induced by GTN and SNP was assessed by cold and hot plate tests in male Swiss albino rats. A single oral administration of low doses of the extract or hypericin reversed the induced prolonged allodynia and hyperalgesia, whereas hyperforin and flavonoids were ineffective. The increased CREB and STAT1 phosphorylation, the activation of NF-κB in periaqueductal grey matter and thalamus, and the increased expression and phosphorylation of PKCγ/ε isoforms after GTN and SNP administration were prevented by the extract and hypericin [Galeotti 2012].

Alcohol withdrawal
In cAA rats, a genetic model of alcoholism, acute i.p. administration of IMI (3-30 mg/kg), FLU (1-10 mg/kg) or an ethanolic extract (50% m/m; 10-40 mg/kg) dose-dependently reduced alcohol intake in a 12-h limited access two-bottle [ethanol 10% (V/V) *versus* water] choice procedure; with minimal effective doses of 30, 5 and 20 mg/kg respectively. The anti-alcohol effects of FLU and the extract appeared to be specific, as reductions in alcohol intake co-incided with reductions in alcohol preference [De Vry 1999].

Upon administration of single oral doses of 100, 200, 400, 600 and 800 mg/kg of a methanolic extract (80%, V/V; 0.22% hypericin, 4.05% hyperforin), alcohol intake was dose-dependently reduced in alcohol-preferring rats. Repeated application of 400 mg/kg for 15 days did not induce tolerance of this effect [Rezvani 1999].

Acute intragastric administration of 125 - 250 mg/kg of an ethanolic extract (50%; 0.3% hypericin) reduced alcohol intake of alcohol-preferring male msP rats by 30 - 40% [Perfumi 1999].

The application of an ethanolic extract (50%; 0.3% hypericin and 3.8% hyperforin) by 3 intragastric administrations of 250 mg/kg to male msP rats produced positive results in the model of the alcohol-preferring rat. The inhibition observed was neither modified by the σ receptor antagonist rimcazole nor by the neurotoxin 5,7-dihydroxytryptamine [Panocka 2000].

Administration of a methanolic extract (0.3% hypericin, 3.8% hyperforin; E1) or a CO_2 extract (24.33% hyperforin, very low hypericin content; E2) to alcohol preferring male msP rats dose-dependently reduced ethanol intake, with E2 being approximately 8-times more potent than E1. Food and water intakes were not affected [Perfumi 2001].

In the same model the effect on ethanol intake of msP rats was investigated 1h after intragastric administration of a CO_2 extract. Naloxone (NAL:1, 3, or 5 mg/kg) or naltrexone (NTX; 0.5, 1, or 3 mg/kg) were given by i.p. injection 10 min before the extract. The extract alone reduced ethanol intake at 31 or 125 mg/kg, but only at 7 mg/kg when combined with NAL. These doses neither modified food or water intake, nor reduced 0.2% saccharin intake. NAL alone significantly reduced ethanol and food intake at 3 or 5 mg/kg, but not at 1 mg/kg. When NAL was combined with each dose of the CO_2 extract, the attenuation of ethanol intake was more pronounced than after the administration of the extract alone. NTX alone reduced ethanol intake at 1 and 3 mg/kg, but not at 0.5 mg/kg. When

NTX 0.5 mg/kg was combined with the CO_2 extract at 7 mg/kg, ethanol intake was markedly reduced [Perfumi 2003].

In C57BL/6J alcohol-preferring mice oral administration of a crude methanolic extract was compared with i.p. administration of a hyperforin-rich CO_2 extract (45% hyperforin). The dose of the hyperforin-rich extract required to significantly ($p<0.05$) reduce 10% ethanol intake was 5 mg/kg, and was 125-fold less than that required for the methanolic extract (625 mg/kg), and comparable to the dose of FLU (10 mg/kg i.p.). None of the treatments significantly affected water intake [Wright 2003].

Intragastric administration of a CO_2 extract (24.33% hyperforin, 0.08% hypericin) significantly reduced ethanol self-administration in alcohol preferring male msP rats at doses of 31 or 125 mg/kg but not 7 mg/kg, when given 1h prior to ethanol access. It did not modify saccharin self-administration. The extract at 31 and 125 mg/kg abolished the increased ethanol intake following ethanol deprivation ($p<0.05$ and $p<0.01$ respectively) [Perfumi 2005b].

In a similar study, repeated intragastric administration of a CO_2 extract, alone or combined with NTX (0.5 or 3 mg/kg i.p.) daily for 12 days, markedly reduced ethanol intake at 125 mg/kg ($p<0.01$), but not at 7 mg/kg. The same dose of the CO_2 extract slightly reduced the simultaneous intake of food, but only on days 3 and 11 of treatment. Rats promptly recovered baseline ethanol intake when treatment did not precede access to ethanol (on day 8) or after the end of treatment (days 13 and 14). Repeated i.p. treatment with NTX reduced ethanol intake at 3 mg/kg ($p<0.001$), but not at 0.5 mg/kg. The extract (7 mg/kg) combined with NTX (0.5 mg/kg) synergistically evoked a significant ($p<0.001$) reduction of ethanol intake. The effect on ethanol intake of the combined treatment remained stable over the 12 days of treatment [Perfumi 2005a].

In ethanol-dependent adult male Wistar rats an ethanolic extract (50%; 25-200 mg/kg i.p.) given just before ethanol withdrawal produced a dose-dependent and significant ($p<0.05$) inhibition of locomotor hyperactivity 2 and 6 hours after withdrawal, and significantly ($p<0.05$) reduced the number of stereotyped behaviours. The extract produced significant inhibitory effects on tremor (50 and 100 mg/kg; $p<0.05$) and audiogenic seizures (100 mg/kg, $p<0.05$) during the withdrawal period [Coskun 2006].

Nicotine withdrawal
Male Swiss mice received nicotine (2 mg/kg, s.c. four injections daily) for 14 days. An extract was administered at various doses (125-500 mg/kg p.o.) immediately after the last nicotine injection. In a further experiment a dose of 500 mg/kg of extract was administered with nicotine at various points during the study period. The reduction of locomotor activity induced by nicotine withdrawal was abolished by the extract, which also significantly ($p<0.05$ to $p<0.01$) and dose-dependently reduced the total nicotine abstinence score when injected after nicotine withdrawal [Catania 2003].

Male Swiss mice were divided into several treatment groups (n=6 each): Group 1: saline i.p. injection, 4 times daily for 14 days; Group 2: nicotine (2 mg/kg i.p.) 4 times daily for 14 days to induce nicotine dependence; Groups 3-5: nicotine protocol plus administration (125 to 500 mg/kg p.o.) of a flavonoid-enriched ethanolic extract (60%; 0.3% hypericin, 4.5% hyperforin, 50% flavonoids) immediately after the last nicotine injection for 30 days after nicotine withdrawal; Group 6: saline protocol plus the extract at 500 mg/kg after the last saline injection for 30 days (no nicotine). In a further group, animals treated with nicotine (14 days), alone or with the extract, were co-administered with a single s.c. dose of saline or the selective 5-HT receptor antagonist WAY 100635 (1 mg/kg i.p.). Brain 5-HT metabolism was evaluated in the cortex 30 days after nicotine withdrawal through evaluation of 5-HT, 5-HIAA and the 5-HIAA/5-HT ratio. The total abstinence score was significantly ($p<0.01$) reduced in mice given the extract (500 mg/kg) after nicotine withdrawal compared to the nicotine control group. WAY 100635 significantly ($p<0.01$) inhibited the reduction of total abstinence score induced by the extract. A reduction of 5-HT content was observed after nicotine withdrawal. A significant increase of cortical 5-HT content was found in animals treated with the extract, with a concomitant significant increase of 5-HT_{1A} receptors [Mannucci 2007].

Opioid withdrawal
In morphine-dependent adult male Wistar rats signs of withdrawal were induced by naloxone (3 mg/kg i.p.) given 4 h after the last injection of morphine on day 7 of morphine treatment. The manifestations of withdrawal were significantly ($p<0.001$) inhibited by co-administration of the morphine (dose increased daily from 2.5 to 50 mg/kg) with an unspecified aqueous extract (p.o. 0.4 mL/200 g, 0.8 mL/200 g and 1.2 mL/200 g per gavage) or clonidine (0.2 mg/kg i.p.). Clonidine was more effective than the extract at 0.4 mL/200 g. There was no significant difference in the mean frequency of withdrawal signs between clonidine and the extract at 0.8 mL/200 g. The extract at a dose of 1.2 mL/200 g exhibited significantly ($p<0.05$) greater attenuation of morphine withdrawal signs than clonidine [Feily 2009].

Sprague-Dawley rats were treated orally with an opium extract (increasing from 80–650 mg/kg) along with an ethanolic St. John's wort extract (70%; 20 mg/kg), either twice daily for 8 days (chronic use), or acutely as a single dose 1 h before induction of opium withdrawal with naloxone. Chronic use of the extract significantly ($p<0.05$) reduced withdrawal signs including stereotype jumps and wet dog shake number when compared to saline control, and decreased rectal temperature at 30 min ($p<0.05$), 60 min ($p<0.01$) and 120 min ($p<0.05$). Acute use of the extract reduced withdrawal-induced diarrhoea ($p<0.05$ vs. saline) [Khan 2014].

Antiaggressive effects
After oral administration of hydroethanolic preparations with defined amounts of hypericin (equivalent to 2-12 mg/kg), aggressive behaviour was significantly reduced in mice after 3 weeks of daily treatment with extract equivalent to 6 or 12 mg/kg of hypericin [Okpanyi 1987].

The antiaggressive activity of hyperforin was investigated in several rodent models using adult male Charles Foster rats and male Wistar mice. Animals were screened for aggressive behaviour, divided into three groups and treated once daily, for seven consecutive days, with A: lorazepam (2.5 mg/kg i.p.), B: hyperforin (10 mg/kg i.p.) or C: vehicle. Hyperforin treatment significantly ($p<0.001$) reduced various aggressive parameters in isolation induced aggression, resident-intruder aggression and foot shock-induced aggression. In the water competition test, hyperforin treatment significantly ($p<0.001$) reduced the duration of water consumption and frequency of water spout possession [Kumar 2009].

Sexual dysfunction
A hyperforin-rich CO_2 extract was examined in an experimental model for the expulsion phase of ejaculation in anesthetised Sprague Dawley rats. The ejaculation model involved inducing rhythmic bulbospongiosus (BS) muscle contractions in male rats under urethane anaesthesia (1.2 g/kg s.c.) by transiently raising the internal urethral pressure with saline infusion. Injection of the 5-HT_{1A} agonist 8-hydroxy-2-(di-*N*-propylamino)

tetralin (8-OH-DPAT) (0.4 mg/kg s.c.) intensified the BS muscle contractions induced by the increases in urethral pressure. The extract (5 to 80 mg/kg i.p.) reduced the effects of 8-OH-DPAT on ejaculation with maximum effect at a dose of 10 mg/kg i.p. The reduction in the amplitude of bursts with the extract remained unchanged after a midthoracic spinal transsection, suggesting that the action of hyperforin is either at the spinal ejaculation generator or directly on the neurons innervating the BS muscles [Thomas 2007].

Anti-inflammatory effects
Anti-inflammatory effects of St. John's wort extracts were studied in carrageenan-induced paw oedema test [Savikin 2007; Zdunic 2009], the indomethacin-induced gastric mucosa damage test [Zdunic 2009] in rats and the croton-oil induced ear oedema test in mice [Sosa 2010] after topical [Sosa 2010], oral [Savikin 2007; Zdunic 2009] and i.p. [Feisst 2009] administration.

A standardised ethanolic (50%) extract was examined for its putative anti-inflammatory and analgesic activity at the daily doses of 100 and 200 mg/kg p.o. The experimental paradigms used were carrageenan-induced paw oedema and cotton pellet-induced granuloma for anti-inflammatory activity; the tail flick, hot plate, and acetic acid-induced writhing methods were used to assess analgesic activity. Indomethacin (20 mg/kg i.p.) was used as an anti-inflammatory active control, while pentazocine (10 mg/kg i.p.) and aspirin (25 mg/kg i.p.) were used as analgesic active controls. The extract showed anti-inflammatory and analgesic activity at both dose levels, in all the paradigms used. In addition, the extract potentiated the anti-inflammatory activity of indomethacin and analgesic activities of pentazocine and aspirin [Kumar 2001a].

A hydroethanolic extract reduced croton oil-induced ear oedema in rodents by 50% ($p<0.05$). From fractionation it was concluded that the anti-inflammatory principle is concentrated in the lipophilic fractions [Brondz 1982].

Administration of an unspecified extract to Sprague-Dawley rats at 50, 150 or 300 mg/kg s.c. dose-dependently produced a significant ($p<0.001$) inhibition of carrageenan-induced oedema, by 53.7, 61.3 and 75.3% respectively, compared to 90% with FLU at 50 mg/kg s.c. and 60.7% with etodolac (ETO) at 72 mg/kg s.c. [Abdel-Salam 2005].

A methanolic extract (0.34% hypericin, 4.1% hyperforin, 5% flavonoids, 10% tannins) ameliorated acute pancreatitis induced by caerulein in male CD mice. The degree of (a) pancreatic inflammation and tissue injury (histological score), ($p<0.05$), (b) expression of ICAM-1, (c) the concentration of nitrotyrosine and poly(ADP-ribose), and (d) MPO activity was markedly reduced after administration of the extract (30 mg/kg p.o.). Moreover, the treatment significantly ($p<0.01$) reduced the mortality rate 5 days after caerulein administration [Genovese 2006a].

The same extract was given at 30 mg/kg p.o. prior to the carrageenan in male CD mice with carrageenan-induced pleurisy. All parameters of inflammation were attenuated by the extract. The carrageenan-induced upregulation of the expression of ICAM-1, and the increases in nitrotyrosine and poly (ADP-ribose), were all significantly ($p<0.01$) reduced by the extract. The extract also inhibited inflammation-induced activation of NF-κB and STAT-3 in the lung [Menegazzi 2006].

The effect of a methanolic (80%) extract on various pro-inflammatory cytokines (IL-1β, IL-2, IL-6, IFN-γ, TNF-α and on intestinal epithelium apoptosis, was investigated in rats treated with irinotecan (60 mg/kg i.v.) for 4 days in combination with the extract or vehicle (400 mg/kg p.o.) for 8 days. The extract markedly reduced irinotecan-induced diarrhoea ($p=0.002$) and intestinal lesions ($p<0.05$) and significantly suppressed the intestinal epithelial apoptosis induced by irinotecan over days 5-11 ($p<0.05$ to $p<0.001$). The extract further significantly inhibited the expression of TNF-α mRNA in the intestine over days 5-11 ($p<0.01$ and $p<0.001$) [Hu 2006].

In the carrageenan-induced rat paw oedema test, ethanolic extracts from various *Hypericum* species were each administered to adult male Wistar rats at doses of 25, 50, 100 and 200 mg/kg p.o. and compared to indomethacin at 1, 2, 4 and 8 mg/kg p.o. or vehicle. All tested doses of the *Hypericum perforatum* extracts demonstrated significantly ($p<0.001$) greater anti-inflammatory activity than the vehicle-treated controls with mean ED_{50} between 47.6 mg/kg and 50.9 mg/kg. The ED_{50} of indomethacin was 2.48 mg/kg. Anti-inflammatory activity was not found to be correlated with the hypericin content of the extracts [Savikin 2007].

An unspecified extract improved the inflammatory and immune response of colonic mucosa in male Wistar albino rats with inflammatory bowel disease (IBD) induced by intracolonic administration of 25 mg 2,4,6-trinitrobenzene sulfonic acid. Treatment with the extract (50, 150 and 300 mg/kg/day i.p.) resulted in significant ($p<0.05$ to $p<0.001$) improvement in the macroscopic scoring of colonic damage, blood levels of catalase, GSH, tissue levels of GSH reductase (GR), MPO activity and GSH-Px [Dost 2008].

Hyperforin (4 mg/kg i.p.) significantly reduced the exudate volume (63%, $p<0.001$), the number of migrating cells (50%, $p<0.001$) and the leukotriene B_4 (LTB_4) formation in pleural exudates (50%, $p<0.001$) of carrageenan-treated rats [Feisst 2009].

Of the three different oil extracts tested, an extract prepared by maceration with 96% ethanol followed by extraction with sunflower oil, given at an oral dose of 1.25 mL/kg, exhibited the highest anti-inflammatory (95.24 ± 11.66%) and gastroprotective activity (gastric damage score of 0.21 ± 0.12) in carrageenan-induced rat paw oedema and indomethacin-induced rat gastric mucosa damage. Its major components quercetin and I3,II8-biapigenin (at 8 mg/kg p.o.) showed a significantly ($p<0.05$ and $p<0.01$ respectively) greater anti-inflammatory activity than the sunflower oil control and comparable with indomethacin (8 mg/kg p.o.; $p<0.001$), as well as significant gastroprotective activity ($p<0.05$), compared to indomethacin [Zdunic 2009].

Topical anti-inflammatory effects of a hydroalcoholic extract, a lipophilic extract and an ethylacetate fraction, as well as isolated constituents, were investigated in croton oil-induced ear oedema in mice. The hydroalcoholic extract (100 - 1000 μg/cm^2), the lipophilic extract (100 - 1000 μg/cm^2), and the ethylacetate fraction (30 - 1000 μg/cm^2) were applied topically to mouse ears. The hydroalcoholic extract was less potent than the lipophilic extract and ethylacetate fraction (ID_{50} > 1000 μg/cm^2, 220 μg/cm^2 and 267 μg/cm^2 respectively). Amentoflavone, hypericin, hyperforin dicyclohexylammonium salt and adhyperforin showed ID_{50} values of 0.16 μmol/cm^2, 0.25 μmol/cm^2, 0.25 μmol/cm^2 and 0.30 μmol/cm^2 respectively. Indomethacin resulted in an ID_{50} of 0.26 μmol/cm^2 [Sosa 2010].

In carrageenan-induced rat paw oedema in male Wistar Han rats administration of hyperforin (4 mg/kg i.p.) significantly reduced the exudate volume (64%; $p<0.001$) and suppressed LTB_4 formation (50%; $p<0.01$) in pleural exudates. The effects were similar to i.p. administration of 10 mg/kg of the 5-LO inhibitor zileuton (77%, $p<0.001$ and 65%, $p<0.001$, respectively) [Feisst 2009].

Various extracts inhibited several members of the immunoglobulin superfamily of cell adhesion molecules, specifically intercellular cell adhesion molecule-1 (ICAM-1) and vascular cell adhesion molecule-1 (VCAM-1) [De Paola 2005; Genovese 2006a; Menegazzi 2006] as well as P-selectin in mice and rats [De Paola 2005].

A methanolic extract (0.34% hypericin, 4.1% hyperforin, 5% flavonoids, 10% tannins) was given orally for eight days at a dose of 2 mg/kg/day to male Sprague Dawley rats following ligature-induced periodontitis. The extract exerted potent anti-inflammatory effects, significantly ($p<0.05$ to $p<0.01$) reducing all measured parameters of inflammation [Paterniti 2010].

An olive oil extract (A), an ethanolic (96%) extract (B) and fractions of the ethanolic extract (*n*-hexane, chloroform and ethyl acetate) were assessed for their anti-inflammatory activity in acetic acid-induced increased capillary permeability. A dose-dependent anti-inflammatory activity was found for the ethanol extract, the ethyl acetate subfraction and fractions containing hyperoside, isoquercitrin, rutin, (-)-epicatechin and hypericin [Süntar 2010].

An unspecified extract (150, 300 and 450 mg/kg p.o.) given for 26 days improved irritable bowel syndrome (IBS) induced by 5-day restraint stress in male Wistar rats. FLU and loperamide (LOP) were used as positive controls. Gastric emptying, small bowel and colon transit, as well as the levels of TNF-α, MPO, lipid peroxidation, and antioxidant power in colon homogenates were determined. A significant reduction in small bowel ($p<0.05$) and colonic ($p<0.001$) transit (450 mg/kg), TNF-α ($p<0.001$), MPO ($p<0.001$), and lipid peroxidation ($p<0.05$ to $p<0.001$) and an increase ($p<0.001$ each) in antioxidant power in all extract-treated groups were seen as compared with the control group [Mozaffari 2011].

Administration of hyperforin (4 mg/kg i.p.) to rats reduced exudate volume and leukocyte numbers in carrageenan-induced pleurisy associated with reduced PGE_2 levels, and inhibited carrageenan-induced mouse paw oedema formation with an ED_{50} (1 mg/kg) superior to that of indomethacin (ED_{50} = 5 mg/kg) [Koeberle 2011].

An unspecified ethanolic extract (30-300 mg/kg i.p.) dose-dependently reduced paracetamol-induced lethality in male Swiss mice ($p<0.05$). The paracetamol-induced increase in plasma AST and ALT concentrations, in hepatic MPO activity and IL-1β, TNF-α and IFN-γ concentrations, as well as reduced GSH concentrations and decreased capacity to reduce 2,2′-azinobis-(3-ethylbenzothiazoline-6-sulfonate radical cation) were inhibited ($p<0.01$) by the extract at 300 mg/kg [Hohmann 2015].

Wound healing

An olive oil extract (A), an ethanolic (96%) extract (B), and fractions of the ethanolic extract (*n*-hexane, chloroform and ethyl acetate), showed wound healing activity in excision and incision wound models in male Sprague-Dawley rats. Extract A had a significant wound healing effect on excision (5.1-82.6% inhibition, $p<0.001$) and circular incision (20.2-100.0% inhibition, $p<0.001$) wounds. The ethyl acetate fraction was the most active, inhibiting excision wounds by 17.9% to 100.0% and incision wounds by 9.4% to 100.0% [Süntar 2010].

A study investigated the therapeutic efficacy of the topical and systemic administration of an unspecified extract on chemo-therapy induced-mucositis. Oral mucositis was induced in 72 male golden hamsters by administration of 5-fluorouracil (5-FU; 60 mg/kg i.p.) on days 0, 5 and 10 of the study. The cheek pouch was scratched with a sterile needle on days 1 and 2. The extract was administered orally (300 mg/kg) and topically (10% extract gel) on days 12-17. Both of the extract treatment groups demonstrated a significant (both $p<0.01$) relief in oral mucositis compared to the control and base gel group [Tanideh 2014].

The efficacy of an unspecified extract for prevention of post-operative left uterine horn adhesion formation was studied in female Wistar rats. Group 1 (control): closure of abdominal incision. Group 2: closure after i.p. administration of Ringer's lactate (RL) solution. Group 3: closure after i.p. administration of olive oil (vehicle). Group 4: closure after i.p. administration of the extract. Fourteen days later, re laparatomy was performed and surgical adhesion scores, inflammation and fibrosis scores were determined. Groups did not differ in inflammation and fibrosis scores [Hizli 2014].

Bone formation

The effect of an aqueous extract on bone formation in the expanded premaxillary suture model was studied in male Wistar rats. Four groups of rats were investigated: control (A); only expansion (B); the extract given (21 mg/day p.o.) only during the expansion and retention period (a total of 17 days) (C); and the extract given during the nursery phase before expansion (40 days), and during the expansion and retention periods (a total of 57 days) (D). After the 5-day expansion period was completed, the rats in the B, C, and D groups underwent 12 days of mechanical retention, following which they were killed, and their premaxilla dissected and fixed. Histological examination was performed to determine the number of osteoclasts and capillaries, as well as the number of osteoblasts, inflammatory cell infiltration, and the amount of new bone formation. The number of osteoclasts and capillaries, and the inflammatory cell infiltration, as well as new bone formation, were higher in the extract groups C and D than in the other groups. Among these two groups, all parameters were higher ($p<0.01$) in group D than C [Halicioglu 2015].

Gastrointestinal motility

The effect on gastric motility of a standardised extract (details unknown) at doses of 100, 300 and 600 mg/kg/day p.o. was investigated in male Wistar rats. The extract delayed gastric emptying ($p<0.05$). The effect of the extract on electrical field stimulation (EFS)-induced contractions was unaffected by drugs inhibiting intrinsic inhibitory nerves or by tachykinin antagonists, but reduced by the 5-HT antagonist methysergide. The inhibitory effect of the extract on ACh-induced contractions was reduced by the sarcoplasmic reticulum Ca^{2+}-ATPase inhibitor cyclopiazonic acid ($p<0.001$), but not by the L-type Ca^{2+} channel blocker nifedipine or by methysergide. Among the chemical constituents of the extract, hyperforin ($p<0.05$ to $p<0.001$) and, to a lesser extent, the flavonoids kaempferol ($p<0.01$) and quercitrin ($p<0.05$), inhibited ACh-induced contractions [Capasso 2008].

Gastroprotective effects

Injection of an unspecified extract (50, 125 or 250 mg/kg s.c.) to pylorus-ligated rats decreased gastric acid secretion ($p<0.05$), but dose-dependently increased ($p<0.05$) indomethacin-induced gastric mucosal lesions [Abdel-Salam 2005].

Three oil extracts, prepared according to traditional prescriptions, were studied in the indomethacin-induced rat gastric mucosa damage test. All extracts possessed gastroprotective activity. The extract prepared by maceration with 96% ethanol, followed by extraction with sunflower oil, had the highest content of quercetin and I3,II8-biapigenin (129 ± 9 µg/mL and 52 ± 4 µg/mL respectively). Quercetin and I3,II8-biapigenin given separately at a dose of 8 mg/kg p.o. exhibited significant (both $p<0.05$) gastroprotective activity [Zdunic 2009].

Gastric mucosal damage induced by hypothermic restraint stress in Wistar rats was improved by an unspecified extract (25, 50 or 100 mg/kg/day p.o.) given over 3 days. The extract significantly reduced lesions compared to placebo by 65, 95 and 75% respectively (p=0.001). Treatment with ranitidine (5 mg/kg s.c.) also reduced ulcers significantly (p=0.001) compared with the placebo groups [Cayci 2009].

Metabolic effects
The hypocholesterolaemic effect of a flavonoid-rich extract (FEHP) was studied in male Wistar rats receiving either a cholesterol-rich (2%) or a standard diet for 16 weeks combined with a daily oral dose of FEHP (0, 25, 75 and 150 mg/kg). The cholesterol-rich diet induced hypercholesterolemia with elevated serum levels of total cholesterol (TC) and triglycerides (TG), and lowered LDL. Daily medium (75 mg/kg) and high doses (150 mg/kg) of FEHP decreased (all $p<0.05$) the serum levels of TC, TG and LDL, and increased ($p<0.05$) serum levels of HDL. Serum and liver contents of MDA were decreased ($p<0.05$) after FEHP compared with cholesterol-rich diet alone. FEHP increased ($p<0.05$) the activity of SOD in serum and liver, whereas the activity of CAT was elevated only in the liver [Zhou 2005].

A study evaluated the effect of an unspecified extract (0.1% hypericin, 3.8% hyperforin) in an experimental model of binge eating (BE). BE for highly palatable food (HPF) was evoked in female Sprague-Dawley rats by three 8-day cycles of food restriction/re-feeding and acute stress on the test day (day 25). Stress was induced by preventing access to HPF for 15 min, while rats were able to see and smell it. Only rats exposed to both food restrictions and stress exhibited BE. The oral doses of 250 and 500 mg/kg but not 125 mg/kg of the extract significantly ($p<0.05$ and $p<0.01$ respectively) reduced the BE episode. The same doses did not affect HPF intake in the absence of BE [Micioni Di Bonaventura 2012].

Ovariectomised (OVX) rats were treated orally for 6 weeks with a 70% ethanolic extract of whole plants (A) or a 70% ethanolic extract of flowers and leaves (B), β-oestradiol-3-benzoate (50 µg/kg/day) or vehicle. OVX increased body weight gain and adiposity, showed higher food efficacy ratio and increased serum cholesterol as well as insulin resistance while reducing uterus weight and uterine epithelial proliferation rate. Extracts A and B showed an oestrogen-like effect on body weight gain, adipose tissue weight and food efficacy ratio in OVX rats. The extracts prevented hypercholesterolaemia induced by OVX more effectively ($p<0.05$) than β-oestradiol-3-benzoate [You 2014].

An ethanolic (50%) extract significantly improved glucose metabolism in STZ-induced diabetic Wistar rats ($p<0.01$, $p<0.001$; 125 and 250 mg/kg i.p. for seven days) [Can 2011a].

In STZ-diabetic Charles Foster rats, an ethanolic (50%) extract given orally at 100 and 200 mg/kg significantly ($p<0.001$) reduced diabetes-induced elevated blood glucose levels [Husain 2011a].

Male STZ-induced diabetic albino rats received an ethyl acetate extract at 50, 100 and 200 mg/kg p.o. for 15 days. At the end of the treatment the extract showed a dose-dependent decrease in fasting blood glucose (FBG). Thirty minutes after administration, FBG was reduced significantly ($p<0.01$) when compared with controls. The extract caused a significant reduction in ($p<0.05$ to $p<0.01$) plasma glucose level, serum total cholesterol, triglycerides and glucose-6-phosphatase levels. Tissue glycogen content, HDL and glucose-6-phosphate dehydrogenase were significantly ($p<0.01$) increased compared with diabetic controls [Arokiyaraj 2011].

A hydroalcoholic extract (50%; 3% hyperforin, 0.3% hypericin) given at doses of 100 and 200 mg/kg orally over 15 days led to lowered total cholesterol and low-density cholesterol in normal Charles Foster rats. In high-fat-fed rats, the extract significantly ($p<0.001$) inhibited weight gain. In fructose-fed rats, the extract normalised the fructose-induced dyslipidaemia ($p<0.01$) and improved insulin sensitivity ($p<0.001$) [Husain 2011b].

A 95% ethanolic extract was given orally to diet-induced obese (DIO) C57BL/6J mice at doses of 50 and 200 mg/kg. The extract significantly improved glucose and lipid metabolism, lowered glucose AUC ($p<0.01$ and $p<0.001$) and fasting insulin levels (both $p<0.01$), improved insulin receptor sensitivity (HOMA-IR) ($p<0.01$ and $p<0.001$) and decreased serum triglyceride levels ($p<0.05$ and $p<0.01$) as compared to control [Tian 2015].

Reperfusion injury
The effect of an unspecified extract on splanchnic artery occlusion (SAO) shock-mediated injury was studied in male Sprague-Dawley rats. SAO shock was induced by clamping the superior mesenteric artery and the celiac trunk for 45 min. After 1 h of reperfusion, SAO-shocked rats developed a significant ($p<0.01$) fall in mean arterial blood pressure. Treatment of rats with an unspecified extract (applied at 25 mg/kg i.v. over 15 min before reperfusion) significantly ($p<0.01$) reduced the fall in mean arterial blood pressure and the migration of polymorphonuclear cells caused by SAO-shock. The extract also attenuated the ileum injury (histology) as well as the increase in the tissue levels of MPO ($p<0.01$) and MDA caused by SAO shock in the ileum. The extract markedly reduced the intensity and degree of P-selectin ($p<0.01$) and ICAM 1 ($p<0.01$) in tissue section from SAO-shocked rats. The extract also significantly ($p<0.01$) improved survival [De Paola 2005].

An ethanolic (70%) extract was studied for its effects on hepatic ischaemia-reperfusion (I/R) injury in rats which were subjected to 45 min of hepatic ischaemia followed by 60 min of reperfusion. The extract (50 mg/kg i.p. 15 min prior to hepatic ischemia) significantly (all $p<0.05$) decreased the ALT, AST, LDH and MDA levels, and markedly increased ($p<0.05$) activities of CAT and GPx in tissue homogenates compared to I/R-induced rats without treatment [Bayramoglu 2013].

The effects of montelukast and an unspecified extract against I/R-induced intestinal damage were investigated. Hamsters were divided into 4 groups after midline abdominal laparatomy: control, I/R group, montelukast and I/R (MIR) group, and extract and I/R (HPIR) group. After 60 min of ischaemia through obstruction of the superior mesenteric artery, 24 h of reperfusion was maintained. Ten minutes prior to the reperfusion period, the MIR group received montelukast (7 mg/kg i.p.) and the HPIR group received the extract (7 mg/kg i.p.). Montelukast and the extract significantly reduced MDA levels and increased GSH levels compared to the I/R group ($p<0.008$). A significant difference was also found between the I/R group and MIR and HPIR groups in terms of MPO levels ($p<0.008$). The MIR and HPIR groups showed increased cardiotrophin-1 levels compared to the control and I/R groups ($p<0.008$ for all) and significantly lower histological scores compared to the I/R group ($p=0.03$ and $p=0.007$ respectively) [Ocak 2014].

Albino rats were subjected to 45 min of hepatic ischaemia followed by a 60 min reperfusion period. An ethanolic extract (70%; 50 mg/kg) was injected as a single i.p. dose, 15 min prior to hepatic ischaemia. Biochemical investigations of serum and liver tissue resulted in significantly increased ALT, AST, LDH and MDA levels whereas CAT and GPx were significantly decreased in I/R-induced control compared to normal control ($p<0.05$). Treatment with the extract significantly decreased

the ALT, AST, LDH and MDA levels, and markedly increased activities of CAT and GPx compared to I/R-induced rats (all $p<0.05$) [Bayramoglu 2014].

The effect of an ethanolic (96%) extract on I/R injury of the liver was investigated in male Wistar-albino rats divided into five groups: Sham group, I/R group (who underwent partial liver I/R protocol), carboxymethyl cellulose (CMC) group administered 0.5 % carboxymethyl cellulose for a week before I/R, and the extract group (HP) receiving 0.5 % carboxymethyl cellulose with the extract (400 mg/kg) for a week before I/R. Blood levels of ALT, TNF-α, IL-6 and MDA were significantly ($p<0.05$) lower in the extract group compared with the I/R and CMC groups ($p<0.05$). There was no difference between the liver injury scores of I/R and CMC groups [Aydin 2014].

Nephroprotection
Male Wistar rats were treated with an unspecified extract (400 mg/kg/day p.o.) for 10 consecutive days, and were injected with cisplatin (5 mg/kg i.v.) one day after the final extract administration. Cisplatin treatment increased ($p<0.01$) the serum creatinine level to 1.5 ± 0.2 mg/dL (mean±SE) from 0.3 ± 0.1 mg/dL (control) on day 5 after injection. This increase was improved significantly ($p<0.01$) to 0.9 ± 0.1 mg/dL by pre-treatment with the extract. Cisplatin-induced histological abnormality of the kidney was blocked by the pre-treatment. Extract administration resulted in increases in renal metallothionein (MT) and hepatic multidrug resistance protein 2 (Mrp2) to 164.8 ± 13.0% and 220.8 ± 39.3% of control levels respectively. GSH levels in the kidney and liver were not changed. Total and free cisplatin concentration in serum was not influenced by the extract [Shibayama 2007].

Antiviral effects
A dose-dependent anti-viral effect of hypericin and pseudohypericin against retrovirus infection with Friend leukaemia virus was confirmed in BALB/cJ, BALB/cBy and C57BL/6J mice after a single i.v. dose of up to 150 µg. Both compounds inactivated infectivity and reverse transcriptase activity of intact viruses. Hypericin was more effective than pseudohypericin [Lavie 1989]. In a further experiment the efficacy of both compounds against radiation leukaemia virus was shown [Meruelo 1988].

The efficacy of an unspecified extract (50 to 200 mg/kg b.w. p.o. twice daily for 5 days) against influenza A virus (IAV) was investigated in BALB/c mice. Protection rate, mean survival days, lung index and viral titre, as well as the secretion of IL-6, IL-10, TNF-α and IFN-γ in lung tissue and serum were measured on days 3 and 5 post-infection. The extract dose-dependently reduced the lung index and viral titre ($p<0.05$ to $p<0.01$) of infected mice, decreased mortality, and prolonged the mean survival time ($p<0.01$). It decreased the concentration of IL-6 at the highest dose ($p<0.05$) and TNF-α ($p<0.01$) in lung tissue and serum on day 5 post-infection. The lung and serum levels of IL-l0 ($p<0.01$) and IFN-γ ($p<0.01$) on days 3 and 5 post-infection were enhanced in a dose-dependent manner [Xiuying 2012].

The immune-regulatory effect of an ethanolic (95%) extract was evaluated in A549 lung epithelial cells and BALB/c mice exposed to influenza A/PR/8/34 H1N1 virus. In A549 cells, the extract (30 µg/mL) significantly ($p<0.05$) inhibited influenza virus induced monocyte chemotactic protein (MCP)-1 and IFN-γ induced protein 10 kD (IP-10) ($p<0.05$), but significantly ($p<0.05$) increased IL-6. In mice inoculated intranasally with a high dose of of influenza A/PR/8/34 H1N1 ($10^{7.9}$ EID_{50}), daily oral treatment with the extract at 110 mg/kg increased lung viral titre, bronchoalveolar lavage (BAL), pro-inflammatory cytokine and chemokine levels, and the infiltration of pro-inflammatory cells in the lung 5 days post-inoculation, as compared to ethanol vehicle treated mice. Suppressor of cytokine signalling 3 (SOCS3) transcription was increased by the extract both in A549 cells and BALB/c mice, which could have interrupted the anti-viral immune response and thus led to the inefficient viral clearance and increased lung inflammation. The extract resulted in a minor reduction of viral titre without affecting body weight when mice were inoculated with a lower dose (~$10^{5.0}$ EID_{50}) and the extract was applied in the later phase of infection. Mice challenged intranasally with the high dose of influenza virus suffered from a higher mortality rate when dosed with the extract [Huang 2013].

Immunomodulatory effects
The immumodulatory potential of an ethanolic (95%) extract was investigated in male BALB/c-mice randomly allocated to two groups and immunised with sheep red blood cells (SRBCs) and complete Freund's adjuvant. Mice treated with the extract (110 mg/kg/day i.p.) for the duration of the 2 week study showed a significant ($p<0.001$) increase in the level of anti-SRBC antibody and a significant decrease ($p<0.01$) in the level of cellular immunity (a lower percentage of foot pad thickness) compared to control [Froushani 2015].

Antiproliferative effects
Treatment with hypericin (10 mg/kg i.p.) reduced the growth rate of metastases in breast adenocarcinoma (DA3) in female BALB/c mice and squamous cell carcinoma (SQ2) in male BALB/c mice after resection of primary tumours at stages with presence of lung micro-metastases. Long-term survival in DA3 tumour-excised groups increased ($p<0.001$) from 15.6% in controls to 34.5% after treatment with hypericin (5 mg/kg on day 1, 2.5 mg/kg on day 2 and 1.25 mg/kg on days 3-5 i.p.) prior to surgery. In mice bearing SQ2 tumour metastases, therapy with hypericin increased animal survival from 17.7% in tumour resected controls to 46.1%. Median survival time was prolonged ($p<0.001$) from 52.5 days to 97 days (resected group) and to 190 days in the combination group (surgery + hypericin). The hypericin content in lungs bearing metastases was approximately 2-fold higher than in the lungs of healthy animals, demonstrating the tendency of hypericin to accumulate in primary and metastatic tumours [Blank 2004].

Hyperforin (daily injections of 0.2 µM over 14 days) inhibited the growth of autologous MT-450 breast carcinoma in immunocompetent female Wistar Furth rats to a similar extent as paclitaxel, without any signs of acute toxicity [Schempp 2002a].

Antiangiogenic effects
After s.c. injection with MT-450 mammary carcinoma cells, Wistar rats were treated with peritumoural injections of hyperforin or solvent. Hyperforin (1 – 5 µg/mL) significantly ($p<0.05$) inhibited tumour growth, induced apoptosis ($p<0.05$) of tumour cells and reduced ($p<0.05$) tumour vascularisation [Schempp 2005].

In Wistar albino rats, extensive angiogenesis induced in the cornea and iris by intraocular administration of basic fibroblast growth factor (FGF-2) was effectively inhibited by treatment with hypericin (2 mg/kg i.p.) [Lavie 2005].

An unspecified extract (15 mg/kg/day) or hypericin (15, 45 or 135 µg/kg/day) were given orally to C57BL/6 neonatal mice to investigate retinal neo-vascularisation. Treatment with the extract or hypericin significantly inhibited the degree of retinal neovascularisation ($p<0.05$ to $p<0.001$), but did not affect the area of retinal vasoobliteration. Treatment with the extract or hypericin reduced (both $p<0.05$) phosphorylation of extracellular signal-regulated MAP kinases (ERK) in the retina [Higuchi 2008].

Antioxidant effects
A dry ethanolic extract administered orally to rats at 250 mg/kg/day significantly reduced immobilisation stress-induced lipid peroxidation (measured ex vivo in liver homogenate; 42% protection after 30 days, $p<0.001$) [Tripathi 1999].

The effects of an unspecified extract (0.34% of hypericin, 4.1% of hyperforin, 5% flavonoids, 10% tannins) on the development of zymosan-induced multiple organ dysfunction syndrome were investigated in male CD1 mice. Treatment with the extract (30 mg/kg i.p.), 1 and 6 h after zymosan (500 mg/kg i.p.), attenuated the zymosan-induced peritoneal exudation and migration of polymorphonuclear cells, pulmonary, intestinal and pancreatic injury, and renal dysfunction as well as the increase in MPO in the lung and intestine. Immunohistochemical analysis showed that the increase of iNOS, nitrotyrosine, and poly(ADP-ribose) in lung and intestine tissues from zymosan-injected mice was markedly reduced in mice treated with the extract [Di Paola 2007].

Male albino Wistar rats received pre-treatment with an unspecified extract (4 mg/kg) or quercetin liposomes (25 and 100 mg/kg) 60 min before injection with rotenone (2 mg/kg). All treatments were given i.p. for 45 days. Rotenone increased activities of SOD, GSH GPx and levels of MDA, and decreased the content of reduced GSH ($p<0.05$). Rotenone significantly ($p<0.05$) induced the gene expression of CuZnSOD, MnSOD, CAT and GPx in brain. In contrast, the extract exerted an antioxidant effect which was related to a decrease of MnSOD activity and mRNA levels of some antioxidant enzymes. Treatment with quercetin liposomes resulted in a preservation of the activities of antioxidant enzymes and a decrease ($p<0.05$) in the mRNA levels of these enzymes [Sanchez-Reus 2007].

In a chronic restraint stress model, inflammatory markers, hormonal levels and enzymatic markers of antioxidant capacity such as SOD, GPx and CAT were determined in the hippocampus and hypothalamus of male Sprague-Dawley rats. Oral treatment with an ethanolic (80%, V/V) extract at doses of 125-750 mg/kg resulted in normalisation of the activities of antioxidant enzymes [Grundmann 2010].

The protective properties of an unspecified extract on oxidative stress, apoptosis, and Ca^{2+} entry through transient receptor potential melastatin 2 (TRPM2) and transient receptor potential vanilloid 1 (TRPV1) channels in spinal cord injury (SCI)-induced dorsal root ganglion (DRG) neurons of rats were investigated. Rats received 30 mg/kg p.o. of the extract for three successive days after SCI induction. The SCI-induced TRPM2 and TRPV1 currents and cytosolic free Ca^{2+} concentration were reduced by the extract. The SCI-induced decrease in GPx and cell viability were ameliorated by the extract, as well as the SCI-induced increase in apoptosis, caspase 3, caspase 9, cytosolic ROS production, and mitochondrial membrane depolarisation values in DRG of SCI [Ozdemir 2015].

Photosensitising and photodynamic effects
The time course and skin histopathology of the phototoxic response after a single topical application of hypericin (0.1-1%) and hypericin acetate (0.015-1.5%), with subsequent irradiation (10 J/cm^2, 20 mW/cm^2) were investigated. Methyl-aminolaevulinic acid (Me-ALA) was used as positive control. Application of hypericin on mouse ears resulted in limited phototoxicity, probably due to confined penetration into the epidermal layers. Extended penetration achieved by administration of hypericin acetate evoked a more severe and prolonged response after irradiation, characterised by intense erythema and ear swelling. Skin damage induced by 0.15% hypericin acetate completely recovered without scar formation over 14 days. Hypericin acetate dose-dependently induced equal or more severe phototoxic responses compared with Me-ALA [Boiy 2008].

Pharmacological studies in humans
The effect of a methanolic extract (80%, V/V; 3 × 300 mg/day p.o. for 14 days) on plasma concentrations of testosterone, dihydrotestosterone (DHT), dehydroepiandrosterone sulfate, sex hormone-binding globulin and the combined concentrations of androsterone sulfate (AoS) and epiandrosterone sulfate (epiAoS) was determined in 12 healthy subjects (6 males, 6 females). The extract significantly decreased the combined concentrations of AoS and epiAoS in all subjects ($p=0.02$), and in males ($p=0.04$). The testosterone to DHT ratio was increased without significance in both men and women [Donovan 2005].

A double-blind, randomised, crossover study examined whether a methanolic (80%) extract could reverse low-dose ketamine-induced changes in auditory evoked potentials (AEP) in healthy subjects. Sixteen healthy subjects were given either 2 × 750 mg of the extract or placebo for 1 week. On day 7, a test-battery including AEP, the oculodynamic test (ODT) and a cognitive test were performed before and after an infusion with 4 mg of S-ketamine over a period of 1 hour. S-ketamine led to a significant ($p=0.004$) decrease in the N100-P200 peak to peak (ptp) amplitude after placebo treatment, whereas ptp was significantly increased by S-ketamine infusion in subjects treated with the extract. Cognitive testing and the ODT revealed no significant effect of ketamine-infusion and, therefore, no interaction between the treatments [Murck 2006].

Receptor binding
Patients with major depressive disorder (n=13) were treated twice daily for 6 weeks with either an unspecified extract (600 mg) or the MAO-A inhibitor moclobemide (300 mg). Assessment with [^{11}C]-harmine positron emission tomography found MAO-occupancy of less than 5% for the extract, but 74% for moclobemide [Sacher 2011].

Smoking cessation
In an open, uncontrolled pilot study, 28 smokers of 10 or more cigarettes per day for at least one year were randomised to receive a methanolic (80%) extract at 300 or 600 mg daily for one week before and continuously for 3 months after a target quit date. In addition, all participants received motivational/behavioural support from a trained pharmacist. The point prevalence and continuous abstinence rates were both 18% at 3 months and 0% at 12 months [Barnes 2006].

A methanolic (80%) extract was assessed for its feasibility of use and efficacy in reducing withdrawal symptoms after smoking cessation. A one-arm, uncontrolled study utilised a two-stage group sequential design with a 1-week run-in period between the start of the extract treatment and the designated quit date in smokers (smoking ≥ 10 cigarettes/day). The extract (450 mg) was taken orally twice daily along with cessation counselling messages. Smoking status was determined through self-report and bioverification using carbon monoxide (CO) testing. Among evaluable subjects, the 12-week quit rate was 37.5% (9/24). The extract was generally well tolerated [Lawvere 2006].

In a double-blind study, smokers stopping smoking were randomised to oral treatment with 900 mg methanolic (80%) extract or placebo daily. All participants received weekly behavioural support. The primary endpoints were biochemically confirmed prolonged abstinence and mean weight gain in abstinent smokers 4 weeks after quitting. Six of 71 (8.5%) participants treated with the extract and 9/72 (12.5%) on placebo achieved prolonged abstinence at 4 weeks. At 6 months, 4.2%

of the extract group and 8.3% placebo participants were still abstinent [Parsons 2009].

A standardised hydroalcoholic extract (0.3% hypericin) was given orally to 118 participants at doses of 900 or 1800 mg per day in a randomised, blinded, placebo-controlled, three-arm, dose-ranging clinical trial together with behavioural interventions over 12 weeks. The dropout rate was high (43%). By intention-to-treat analysis, no significant differences were observed in abstinence rates at 12 and 24 weeks between the extract and placebo. The extract neither attenuated withdrawal symptoms in abstinent subjects nor reduced abstinence rates [Sood 2010].

The neurocognitive effects of an ethanolic (50% m/m) extract were compared with nicotine replacement therapy (NRT) and the combination of NRT plus extract during smoking abstinence in 20 smokers aged between 18 and 60 years over a period of 10 weeks during smoking cessation. A spatial working memory (SWM) task was completed at baseline, 4 weeks prior to quitting, as well as at the completion of the study, following the 10 weeks of treatment. Brain activity was recorded during the completion of the SWM task using steady-state probe topography. Reaction time and accuracy on the SWM task were not significantly different between treatment groups at retest. Differences in the steady state visually evoked potentials (SSVEP) treatment profiles were noted: a stronger SSVEP amplitude increase in posterior-parietal regions for the extract and NRT groups, and greater fronto-central SSVEP phase advance in the extract group [Camfield 2013].

Cognitive function
Thirteen healthy volunteers received a methanolic extract (80%, V/V; 900 or 1800 mg/day), AMI (25 mg/day, positive control) or placebo in a double-blind, placebo-controlled study. Cognitive and psychomotor tests, and subjective measures of sedation, were evaluated before and 1, 2 and 4 hours after drug administration. AMI impaired performance on a battery of psychological tests, which included critical flicker fusion, choice reaction time, digit symbol substitution test, profile of mood states and the line analogue rating scale, while the extract did not influence performance in these tests [Timoshanko 2001].

In a randomised, double-blind, crossover study healthy male volunteers received oral doses of either 255-285 mg of an un-specified extract (900 µg hypericin), 25 mg AMI or placebo, three times daily for periods of 14 days each with at least 14 days wash out. Psychometric tests and quantitative EEG (qEEG) were performed before start of medication and on the last treatment day. Neither the extract nor AMI had an influence on cognitive performance such as choice reaction, psychomotor co-ordination, short-term memory and responsiveness to distractive stimuli. AMI, but not the extract, decreased self rated activity ($p<0.05$). Both drugs caused significant qEEG changes. The extract increased theta power density ($p<0.05$). AMI increased theta as well as fast α power density ($p<0.05$) [Siepmann 2002].

Effect on stress hormones
The effects of daily oral administration of a methanolic extract (80%; 300 or 600 mg) or placebo on COR, GH and PRL secretion were examined in twelve healthy subjects. No PRL stimulation was observed. A small but significant ($p<0.05$) elevation in GH AUC values occurred after 300 mg of the extract. After 600 mg of the extract, a distinct COR stimulation was observed ($p<0.05$ to $p<0.01$), occurring from 30 up to 90 min after administration [Schüle 2001].

In a similar study, the effects of oral administration of a methanolic (80%) extract, at doses of 600, 900 and 1200 mg on 4 different days, on the COR, ACTH, GH and PRL secretions were examined in 12 healthy male volunteers. A significant ($p=0.044$) stimulatory effect of the extract on ACTH secretion was observed, whereas COR, GH and PRL secretions were not significantly influenced [Schüle 2004].

In a double-blind, randomised, placebo-controlled, crossover study, 16 healthy subjects (11 men and 5 women) received either an ethanolic extract (60%; 300 mg three times daily) or placebo for 7 days. IMI treatment (50 mg three times daily) in 7 subjects served as a positive control. The extract had no effect on plasma concentrations of NE and its main metabolite, dihydroxyphenylglycol, whereas plasma DOPAC (the main metabolite of DA) concentrations were significantly ($p=0.04$) increased (1661 ± 924 pg/mL) compared to placebo (1110 ± 322 pg/mL) [Schroeder 2004].

The effects of two doses of a methanolic (80%) extract on evening salivary cortisol and NE-mediated melatonin were studied. Twenty healthy male volunteers received either a low (2 x 300 mg/day) or high (2 × 900 mg/day) dose of the extract for 7 days. The extract significantly ($p<0.01$) increased salivary COR in the low dose group but had no discernible effect in the high dose group. Salivary melatonin was not increased in either group [Franklin 2006].

Autonomic nervous function
In a randomised, double-blind, placebo-controlled study in 12 healthy male subjects, the effects of an unspecified extract (standardised to 900 µg hypericin) on the autonomic responses of blood vessels and sweat glands were compared with those of AMI and placebo. Subjects received oral doses of 255 to 285 mg of the extract, 25 mg of AMI and placebo 3 times daily for 14 days each, with at least 14 days washout. The extract affected neither the vasoconstrictory response (VR) of cutaneous blood flow nor the skin conductance response (SR). Whereas AMI led to a reduction of SR and a prolonged dilation phase of VR ($p<0.05$) [Siepmann 2004].

The effects on heart rate variability of the same extract and AMI (at the same dosages) were compared to placebo in 12 healthy male volunteers in a randomised, double-blind, crossover study. The extract did not affect heart rate variability, whereas AMI significantly ($p<0.001$) decreased it [Siepmann 2002].

Skin protection
A cream containing 1.5% w/w of a hyperforin-rich (44.3%) CO_2 extract was tested on 20 volunteers in a randomised, double-blind, vehicle-controlled study. It significantly ($p<0.01$) reduced UVB-induced erythema as compared to vehicle. Occlusive application of cream on non-irradiated test sites did not cause any skin irritation [Meinke 2012].

Topical treatment with a 1.5% hyperforin-rich cream increased the radical protection of the skin during VIS/NIR irradiation in 11 volunteers. After a single application, VIS/NIR-induced radical formation was completely inhibited by both verum and placebo ($p<0.05$). After application for 4 weeks, radical formation was significantly reduced by 45% ($p<0.05$) by placebo and 78% ($p<0.01$) by verum. Skin lipids in both verum and placebo groups increased directly after a single application but only significantly ($p<0.05$ and $p<0.01$) for ceramide [AP], ceramide [NP1] and squalene. After long-term application, concentration of cholesterol and ceramides increased without significance [Arndt 2013; Haag 2013; Haag 2014].

Clinical studies: depressive disorders
The efficacy and safety of standardised hydroalcoholic St. John's Wort extracts have been assessed in 54 controlled, double-blind

studies involving 8,327 patients [Anghelescu 2006; Behnke 2002; Bjerkenstedt 2005; Brenner 2000; Engesser 1996; Fava 2005; Gastpar 2005; Gastpar 2006; Halama 1991; Hänsgen 1996; Häring 1996; Harrer 1994; Harrer 1991; Harrer 1999; 2002; Hoffmann 1979; Hübner 1994; Kalb 2001; Kasper 2006; Kasper 2007a; Kasper 2008; Kugler 1990; Laakmann 1998; Lecrubier 2002; Lehrl 1993; Lenoir 1999; Mannel 2010; Martinez 1994; Montgomery 2000; Moreno 2006; Philipp 1999; Quandt 1993; Randløv 2006; Rapaport 2011; Sarris 2012; Schlich 1987; Schmidt 1989; Schrader 2000; Schrader 1998; Shelton 2001; Singer 2011; Sommer 1994; Szegedi 2005; Uebelhack 2004; van Gurp 2002; Vorbach 1997; Vorbach 1994; Warnecke 1986; Werth 1989; Wheatley 1997; Witte 1995; Woelk 2000a] and 15 open studies, drug monitoring studies and numerous case reports [Albrecht 1994; Brattström 2009; Demling 2004; Findling 2003; Grube 1999; Holsboer-Trachsler 1999; Hübner 2000; Meier 1997; Melzer 2010; Mueller 1998; Rychlik 2001; Schakau 1996; SDSGrube 1996; Sepehrmanesh 1999; Simeon 2005] have involved a further 15,359 patients.

The major indication in most of the studies was mild or mild to moderate depressive disorders. Three studies were designed for treatment of severe depressive disorders [Davidson 2002; Shelton 2001; Vorbach 1997]. A significant improvement in main symptoms (mood, loss of interest and activity) and other symptoms of the depressive syndrome (sleep, concentration, somatic complaints) has been demonstrated in many of these trials. The activity has been studied in comparison to placebo and various antidepressants (AMI, IMI, maprotiline, FLU, sertraline (SERT), citalopram (CIT)). Nine meta-analyses [Kim 1999; Linde 2005a; Linde 2009; Linde 1996; Liu 2013; Liu 2014; Raak 2012; Rahimi 2009; Whiskey 2001] and 18 systematic reviews [Clement 2006; Gaster 2000; Hammerness 2003; Hazell 2009; Henderson 2002; Izzo 2001; Izzo 2009; Knüppel 2004; Linde 1998; Linde 2005b; Linde 2005c; Linde 2009; Linde 2011; Posadzki 2013; Raak 2012; Whiskey 2001; Whitten 2006] of clinical trials with different selection criteria have confirmed the efficacy of various St. John's wort extracts in mild to moderate depression, but not in severe depression.

The studies summarised below are grouped according to the preparations tested. Comparability is assumed for hydroalcoholic dry extracts within the range 60% ethanol to 80% methanol on the basis of their similar active constituent profiles [Gaedcke 2000]. An overview of the controlled studies is given in Table 1.

*Clinical studies and post-marketing surveillance studies in **mild to moderate depression** performed with hydromethanolic extracts (80% methanol)*

The DER of the extract used in the following studies was 3-6:1

In a randomised, placebo-controlled study involving 50 patients suffering from psychovegetative depressive symptoms (ICD-09: neurotic depression or depressive mood of short duration), 3 × 300 mg daily, in some cases reduced to 2 × 300 mg after week 2, of an extract led to a substantial improvement after 4 weeks. A reduction of at least half from their initial HAMD total score or a score below 10 after 4 weeks was achieved by 50% of patients under verum ($p<0.01$), but by none in the placebo group. Other parameters, such as the von Zerssen Complaint Score and CGI score, showed similar differences between verum and placebo [Halama 1991].

In a multicentre, placebo-controlled study, 50 patients (mean age 49 years) with depressive symptoms (ICD-09: 300.4 neurotic depression; or 309.0 brief depressive reaction) were treated daily for 4 weeks with either 3 × 300 mg of an extract or placebo. HAMD scores improved from 23.7 to 17.4 in the verum group and from 21.6 to 16.8 in the placebo group, the difference was not significant. In an evaluation of cognitive performance using the short test for general basic capacities of information processing, patients on verum showed slightly better improvement than those on placebo ($p<0.1$) [Lehrl 1993].

In a multicentre, uncontrolled drug surveillance study, 1060 patients (mean age 51 years) with mild to moderate depressive symptoms were assessed over a 4 week period of treatment with 3 × 300 mg daily of an extract. By the end of the study, the average HAMD score had decreased from 18.4 to 5.4 and the D-S score from 21.1 to 7.3. According to CGI evaluation, 66% of patients had improved and 27% were symptom-free [Albrecht 1994].

In a multicentre, randomised, double-blind study, 105 patients (mean age 45 years) with depressive symptoms (ICD-09: 300.4 or 309.0) were allocated to 3 × 300 mg of an extract, or placebo daily for 4 weeks. By the end of the study initial HAMD scores (15.8 points in both groups) had dropped to 7.2 in the verum group and 11.3 in the placebo group ($p<0.01$). Responder rates, defined by a total endpoint score of less than 10 or a

[1)] Daily dosage was up to 50% lower due to up to 50% of excipients in the amount stated [Schulz 1998].
[2)] In the St. John's wort group

drop of at least 50% from baseline values, were 67% and 28% respectively [Sommer 1994].

In a placebo-controlled, randomised, double-blind study, 40 patients (mean age 51 years) suffering from mild depression with somatic symptoms (ICD-09: 300.4; 309.0) were treated with 3 × 300 mg of an extract or placebo daily for 4 weeks. Initial mean HAMD scores of 12.5 dropped to 5.5 in the verum group compared to 10.8 in the placebo group ($p<0.05$). Patients in the placebo group had an improved score of 9 after 2 weeks, but this subsequently increased. Responder rates, defined by an endpoint score of < 10 or a drop of at least 50% from baseline value, were 70% and 47% respectively [Hübner 1994].

In a 4-week randomised, double-blind, comparative study, the efficacy and tolerability of 3 × 300 mg daily of an extract was compared with 3 × 75 mg daily of maprotiline in 102 patients (mean age 46 years) with moderate depression (ICD-10: F 32.1). Initial 17-item HAMD scores decreased from 20.5 to 12.2 in the St. John's wort group and from 21.5 to 10.5 in the maprotiline group. Responder rates, defined by a total endpoint score of less than 10 or a drop of at least 50% from baseline values, were 61% and 67% respectively, with no significant differences between groups [Harrer 1994].

In a 6-week multicentre, randomised, double-blind, comparative study, 3 × 300 mg daily of an extract was compared to 3 × 25 mg daily of IMI. The patients (n = 135; mean age 53 years) had diagnoses in accordance with DSM-III-R criteria of depression with a single episode (296.2), several episodes (296.3), depressive neurosis (300.4) or adjustment disorder with depressed mood (309.0). Initial HAMD scores declined from 20.2 to 8.8 in the extract group and from 19.4 to 10.7 points in the IMI group. Group comparisons showed no significant differences. Analysis of von Zerssen depression scale (D-S) and CGI patterns in the two groups also revealed comparable results. Subgroups with initial HAMD scores of > 21 performed significantly better ($p<0.05$) with the extract (n = 26) than IMI (n = 25) with regard to HAMD score and CGI [Vorbach 1994].

In a multicentre, uncontrolled drug surveillance study, 3250 patients (mean age 51 years), of whom 49% had mild, 46% moderate and 3% severe depressive symptoms, were treated for 4 weeks with 3 × 300 mg daily of an extract. D-S scores dropped from 23.2 to 11.8 over the 4 week period. At the end of treatment, 82% of patients were assessed as improved or symptom-free by the physicians and 79% by self assessment. The therapeutic effect was slightly better in patients less than 50 years old. Cases of mild or moderate depression responded to treatment to the same extent, while severe cases improved less [Woelk 1994].

In an open, randomised, single-blind study involving patients (mean age 46 years) suffering from seasonal affective disorder

(major depression with a seasonal pattern in accordance with DSM-III-R), daily treatment for 4 weeks with 3 × 300 mg of an extract was combined with phototherapy: either bright light (3000 lux; n = 10) or dim light (< 300 lux, n = 10) for 2 hours per day. Average HAMD scores at baseline decreased significantly in both groups ($p<0.001$) [Martinez 1994].

In 102 outpatients (mean age 52 years) with depression of mild or moderate severity (DSM-III-R: 296.2, 296.3), daily treat ment with 3 × 300 mg of an extract for 4 weeks was compared to placebo. Average HAMD scores at baseline were 21 in the verum group and 20.4 in the placebo group. After 4 weeks the average score was significantly lower ($p<0.001$) in the verum group (8.9) than in the placebo group (14.4). Similar results were obtained on the von Zerssen depression scale (D-S) ($p<0.001$). Responder rates were 70% under verum and 24% under placebo ($p<0.001$). The randomised, double-blind period was followed by a further 2-week period when all patients were openly treated with the extract; HAMD scores decreased further, to 6 in the former verum group and more substantially to 8.7 in the former placebo group [Hänsgen 1996].

In a prospective, placebo-controlled, double-blind pilot study, 28 outpatients undergoing chemotherapy for solid tumours were randomly assigned to 3 × 300 mg of an extract or placebo daily for 2-3 chemotherapy treatment cycles. Although the average HAMD score in the verum group showed a slight trend towards improvement, results from the two treatment groups were comparable with respect to a quality of life analysis, the D-S scale and the CGI scale [Häring 1996].

In a 5-week drug monitoring study, the efficacy of an extract (3 × 135-225 mg providing 900 µg of total hypericin daily) was assessed in 114 patients (mean age 48 years) with mild depressive symptoms. The treatment was evaluated by the D-S scale, the distribution of characteristic psychic and somatic symptoms and a global rating by the physician. From an initial score of 21 the D-S score dropped to 15 after 2 weeks and to 2 after 5 weeks. The physicians rated 39% of patients as improved and 35% as symptom-free after the 5 weeks [Grube 1996].

In a 12-week uncontrolled drug-monitoring study, the efficacy of an extract (3 × 135-225 mg, providing 900 µg of total hypericin daily) was assessed in 111 women (mean age 52 years) with menopausal symptoms. Treatment was evaluated by the menopause rating scale (MRS), a questionnaire for assessing sexuality and the CGI scale. Menopausal complaints diminished or disappeared completely in 79% of the women as rated by the physicians (CGI rating better or symptom-free). Sexual well-being was favourably affected in approximately 60%. The average MRS total score decreased from an initial 63.4 (corresponding to a marked intensity of symptoms) to 23.5 (slight intensity) after 12 weeks [Grube 1999].

In an uncontrolled drug-surveillance study, 647 patients with mild to moderate depression were treated daily for 6 weeks with 3 × 300 mg of an extract. Improvement was shown in 75% of the patients. The D-S score dropped from 19.8-21.2 at baseline to 8.1-9.3 after 6 weeks. Patients older than 65 years improved at a slightly slower rate but the severity of depression did not appear to affect the outcome [Holsboer-Trachsler 1999].

In a 6-week multicentre, randomised, double-blind, comparative study, 165 mildly to moderately depressed patients (mean age 40 years) diagnosed in accordance with DSM-IV were treated with 3 × 300 mg daily of an extract or 3 × 25 mg daily of amitriptyline. Initial 17-item HAMD scores were between 17 and 24 (mean 20.7). No significant difference between groups was observed with respect to the response rate (defined as an endpoint HAMD score of less than 10 or a drop of at least 50% from baseline). HAMD scores dropped to 10 in the extract group and to 6 in the amitriptyline group after 6 weeks, a difference significantly in favour of amitriptyline ($p<0.05$). Analysis of the Montgomery-Asberg rating scale for depression (MADRS) also favoured amitriptyline ($p<0.05$) [Wheatley 1997].

In a 6-week multicentre, randomised, double-blind comparative trial, 209 patients (mean age 49 years) were allocated to 3 × 600 mg daily of an extract or 3 × 50 mg daily of IMI. The primary target parameter, mean 17-item HAMD scores, dropped from 25.3 to 14.4 points in the extract group and from 26.1 to 13.4 points in the IMI group, significantly in favour of IMI ($p=0.021$). Equivalence of the two treatments was shown with respect to response rates, defined as the percentage of patients showing a reduction of at least 50% in HAMD total score over the study period: 35.3% in the extract group and 41.2% in the IMI group [Vorbach 1997].

In a hospital-based, double-blind, randomised study, 30 outpatients (18 to 65 years) with an initial 17-item HAMD score ≥17 and a DSM-IV diagnosis of major depressive disorder (single or recurrent episodes), dysthymic disorder, adjustment disorder with depressed mood, or depressive disorder not otherwise specified, were given daily doses of either 2 × 300 mg of an extract or 50 mg SERT. After one week, the extract dose was increased to 3 × 300 mg and SERT to 75 mg daily for a further 6 weeks. Mean HAMD and CGI scores significantly improved during both treatments ($p<0.01$), and no significant differences were observed between the treatments. Comparable clinical response (≥ 50% reduction in HAMD scores) was obtained in 47% of patients receiving the extract and 40% receiving SERT [Brenner 2000].

Adult outpatients (n = 200; mean age 42 years) suffering from recurrent depression (64%) or a single episode of depression (35%) or melancholia (40%) with a DSM-IV diagnosis of major depression and an initial HAMD total score (17-item scale) of at least 20 participated in a randomised, double-blind, placebo-controlled study. The duration of the current major depressive disorder episode was more than 2 years on average and onset of the initial major depressive disorder was more than 10 years ago. After a 1-week single-blind run-in with placebo, patients were treated for 8 weeks with either an extract, 3 × 300 mg daily for 4 weeks, increased thereafter to 4 × 300 mg daily in the absence of adequate response, or placebo. The primary outcome measure (rate of change in HAMD score over the treatment period) was significantly decreased by both treatments ($p<0.001$), with no differences between treatments ($p=0.16$). Similar results were obtained for the secondary outcome measures, HAMA and CGI. 26.5% of patients in the verum group and 18.6% in the placebo group were responders. A significantly higher ($p=0.02$) remission rate (defined as an endpoint HAMD score of 7 or less and CGI-I score of 1 or 2) was determined for the extract (14.3%) compared to placebo (4.9%) [Shelton 2001].

In a multicentre, randomised, placebo-controlled, double-blind, three-armed study, 340 patients (mean age 42 years) with major depression of moderate severity (according to Clinical Interviews for Axis I DSM-IV disorders, initial 17-item HAMD score ≥ 20 and a Global Assessment of Functioning (GAF) score ≤60) were assigned to one of three treatments daily for 8 weeks: 3 × 300 mg of an extract (standardised to 0.12-0.28% hypericin and 3.1% of hyperforin), 50 mg of SERT (divided into 3 doses) or placebo. Responders at week 8 could continue blinded treatment for another 18 weeks. Daily dosage was increased after week 3 to 1500 mg of the extract or to 100 mg of SERT if warranted; the mean highest daily doses prescribed during the 8-week period were 1299 mg of the extract, 75 mg of SERT or

placebo equivalent. With respect to the change from baseline HAMD score and full response rates, defined as an endpoint HAMD score of 8 or less and a CGI-I score of 1 or 2, neither the extract nor SERT were significantly different to placebo. Mean reductions in HAMD scores were 8.7 for the extract, 10.5 for SERT and 9.2 for placebo. Full response rates were 23.9% for the extract, 24.8% for SERT and 31.9% for placebo [HDTSG 2002].

Continuation data from the above study was used to analyse the 124 participants (responders) that continued treatment with an extract (900 – 1500 mg), SERT (50 – 100 mg) or placebo from week 8 until week 26. At week 26, the primary outcome HAMD scores were: extract (6.6 ± 4.5), SERT (7.1 ± 5.4) and placebo (5.7 ± 5.4), with a significant effect for time (p=0.036). Differences between all treatments were not significant (p=0.61). The effects on BDI, CGI-severity, CGI-improvement, and on intention-to-treat analyses were also non-significant [Sarris 2012].

In a double-blind, randomised, placebo-controlled study, 163 out-patients (mean age 50.3 years) with major depressive disorder (MDD) received, after a 3 to 7 day placebo run-in period, one of the following treatments for 4 weeks: 3 × 300 mg daily of an extract, 20 mg daily fluoxetine or placebo. Patients had a current major depressive episode with mild to moderate intensity and a minimal total score of 21 on the 21-item HAMD score, as well as a history of at least two episodes of non-psychotic MDD. During the four weeks treatment, a reduction in HAMD total score was observed from 24.9 to 15.0 in the extract group, from 23.8 to 14.9 in the fluoxetine group and from 25.2 to 9.7 in the placebo group. There was no significant difference for HAMD and treatment response between the treatments. However, with regard to remission, the extract (24%; p=0.02) and fluoxetine (28%; p=0.005) were significantly superior to placebo (7%). Almost identical results for the three groups were attained with the MADRS and CGI [Bjerkenstedt 2005].

In a double-blind, randomised, placebo-controlled study, 135 out-patients (mean age 37.3 years) with MDD received one of the following treatments for 12 weeks after a 1 week placebo run-in period: 3 × 300 mg daily of an extract, 20 mg daily fluoxetine (FLU) or placebo. Patients had a current MDD episode according to DSM-IV of at least 2 weeks duration and a total 17-item HAMD score ≥ 16. In comparison to baseline, treatment with the extract was associated with a significantly ($p<0.05$) greater decrease in HAMD scores compared with fluoxetine at all post-baseline visits, except visit 5 (week 8). There was no significantly greater reduction in HAMD score in the extract and FLU groups when compared with placebo and non-significantly higher rates of remission (HAMD < 8) in the extract group (38%) compared to FLU (30%) or placebo (21%). No significant differences were observed for CGI-S, CGI-I and BDI score between the treatments [Fava 2005].

In an 8-week double-blind, placebo-controlled, randomised trial, 600 mg daily of an extract or placebo were given to patients with vegetative features of atypical depression, e.g. hyperphagia or hypersomnia. One-hundred patients with a mild- and another 100 patients with a moderate severity major depressive episode according to ICD 10, who met a score of 2 in at least one of the items 22–26 of the 28-item HAMD scale, and had an episode duration of at least 3 months, were randomized for treatment. The absolute reduction of the 17-item HAMD was significantly ($p<0.05$) greater for the extract than placebo. No significant benefit was observed for the sum score of the atypical vegetative items of the 28-item HAMD; however, the sum score of the hypersomnia items showed a significant superiority for the extract. The HAMA, PHQ-9, and CGI-I scales demonstrated superiority of the extract ($p<0.01$) [Mannel 2010].

The DER of the extract used in the following studies was 3-7:1

In a double-blind, randomised, placebo-controlled study, 375 out-patients (aged 18 to 25 years) after a one-week placebo run-in period received 3 × 300 mg daily of an extract (standardised to 3-6% hyperforin and 0.12-0.28% hypericin) or placebo for 6 weeks. Patients had a current major depressive episode of at least 2 weeks duration according to DSM-IV (mild or moderate depression, single or recurrent episode), and a total score on the 17-item HAMD score between 18 and 25 and a score on item 1 ("depressed mood") of 2 or higher at screening and baseline. The HAMD score changed from 21.9 to 12.0 in the verum group and from 21.9 to 13.8 in the placebo group (p=0.03). Significantly (p=0.03) more patients had a treatment response or remission in the verum group (52.7%) compared to placebo (42.3%). There was a trend towards greater reduction in the MADRS score for the verum group (p=0.06). The depression sub-score of SCL-58 was not significantly different between treatments [Lecrubier 2002].

In a double-blind, randomised, active-controlled, double-dummy, non-inferiority study, 251 out-patients (mean age 47.3 years) with MDD received one of the following treatments over 6 weeks: 3 × 300 mg daily of an extract (standardised to 3-6% hyperforin and 0.12-0.28% hypericin) or 20 mg daily PAR. Patients had single or recurrent moderate or severe episodes of MDD according to DSM-IV persisting between two weeks and one year. At screening and baseline all participants had to have a total score ≥ 22 points on the 17-item HAMD scale and ≥ 2 points for the item "depressive mood". HAMD decreased from 25.5 to 11.1 in the extract group and from 25.5 to 14.1 in the PAR group, demonstrating that the extract was as effective as PAR. At the end of the treatment, 71% of patients in the extract group and 60% in the PAR group had responded to treatment (p=0.08), and 50% and 35% showed remission (p=0.02) respectively. Patients in the St. John's wort group showed a significantly greater decrease of the MADRS (p=0.01) and BDI scores (p=0.01). Item 1 of the CGI score was signficiantly (p=0.02) improved in ≥ 2 categories in the extract group [Szegedi 2005].

In a multicentre, randomised, double-blind, active controlled study, 133 patients received after a 3-7 days run-in phase, 2 × 300 mg daily of an extract or 20 mg daily PAR for 6 weeks. Patients suffered from single or recurrent episodes of moderate or severe intensity MDD, without psychotic features, according to DSM-IV with a duration of at least two weeks and not more than 1 year. A total score of at least 22 points on the 17-item HAMD scale and an item score of at least 2 for 'depressive mood' were required for inclusion. Patients with a HAMD total score decrease of ≥ 50% during the 6 weeks of acute treatment were asked to continue the treatment for another 16 weeks to prevent relapse. Patients who received the extract in the acute phase were randomised to maintenance doses of either 900 (n = 33) or 1800 mg of the extract daily (n = 38). Patients who received PAR in the acute phase were randomised to maintenance doses of either 20 (n = 28) or 40 mg daily (n = 34) of PAR. Between baseline of the acute phase and end of continuation treatment the total HAMD score decreased from 25.3 ± 2.5 (mean ± SD) to 4.3 ± 6.2 points for the extract and from 25.3 ± 2.6 to 5.2 ± 5.5 points for PAR (p=0.49). Remission (total HAMD score < 8) occurred in 81.6% of the patients in the extract group and in 71.4% of the PAR group (p=0.29). Three patients relapsed (HAM-D increase > 5 points during continuation treatment) in the extract group and two patients in the PAR group. None of the secondary parameters showed any significant difference between the treatments [Anghelescu 2006].

In a double-blind, randomised, placebo-controlled, multicentre study an extract at two doses (600 mg/day; 1200 mg/day) or

placebo were given for 6 weeks to 332 patients with mild to moderate, single or recurrent, major depressive episodes as defined by the DSM-IV. Average total HAMD scores decreased in all three groups between baseline and day 42 ($p<0.001$ each). Both verum groups showed a significantly ($p<0.001$) greater decrease than placebo, from 22.8 to 11.2 (600 mg/day) and from 22.6 to 11.8 (1200 mg/day) versus 23.6 to 17.6 (placebo). CGI, MADRS, SF-36 and global self-rating scores improved significantly ($p<0.001$) for both verum groups compared to placebo [Kasper 2006].

In a double-blind, randomised, placebo-controlled study, relapse of depressive symptoms following 6-weeks single blind treatment with an extract was studied in 426 patients (18–65 years old) suffering from a recurrent episode of major depression (ICD-10 F33.0 or F33.1, and DSM-IV 296.3), and with a history of 2 or 3 previous episodes according to ICD-10 and DSM-IV criteria. After a 1 week single-blind placebo run-in period, the 6 weeks single blind acute treatmen took place. Patients classified as responders to acute treatment were randomised (2:1) to continue in a double-blinded manner with either 3 × 300 mg extract or placebo for 26 weeks. Patients who did not relapse during continuation treatment were entered into a 52-week double-blind maintenance treatment phase. Patients under placebo continued on the same regimen, those treated with the extract were re-randomised at a ratio of 1:1 to maintenance treatment with either 3 × 300 mg/day extract or placebo. Relapse was defined as a 17-item HAMD score ≥ 16, or clinical diagnosis of a depressive episode according to ICD-10 criteria, or premature treatment termination related to lack of efficacy. In the intention-to-treat (ITT) analysis, 51 of 282 (18.1%) patients on verum and 37 of 144 (25.7%) on placebo relapsed ($p=0.035$). The mean time until relapse was 177 days (verum) and 163 days (placebo), $p=0.034$. Compared to baseline, HAMD scores were decreased after the 6 week acute treatment phase from 23.8 to 8.6 in the group randomised to receive verum continuation treatment and from 23.6 to 8.6 in the group randomised to receive placebo. In the continuation treatment period, verum signficantly ($p=0.04$) reduced the HAMD score by a further 1.3, compared to 0.1 with placebo. CGI improved significantly ($p=0.01$) during verum continuation treatment, whereas BDI was comparable [Kasper 2008].

The DER of the extract used in the following studies was 4-7:1

In an uncontrolled, multicentre, drug monitoring study involving 1606 patients (mean age 52 years) suffering from typical depressive symptoms such as low mood, disturbed sleep, loss of interest and energy, more than 90% were treated 2-3 times daily with 300 mg of an extract (standardised to 900 µg of total hypericin). After a mean treatment period of 5 weeks, the intensity of dominating symptoms was markedly reduced. The efficacy was rated as very good or good by 81% of the physicians and 76% of patients. No age-dependent correlation of efficacy was reported [Sepehrmanesh 1999].

In an uncontrolled, multicentre, drug monitoring study, 313 patients received an extract at a dose of 3 × 300 mg daily for 12 months. Patients were suffering from mild to moderate MDD (DSM-IV 296.2 and 296.3), dysthymic disturbances (300.4) or adaptation disturbances (309.0) and had a baseline 17-item HAMD score between 12 and 22, as well as a CGI score of 4 to 6. At the end of treatment, the HAMD score decreased from 17.4 to 7.1 ($p<0.001$). Responder rate (HAMD score < 10 and HAMD reduction of at least 50%) was 68.7% [Hübner 2000].

In an uncontrolled study an extract was given for 4 to 6 weeks to paediatric patients (n = 101; 1 to 12 years) with symptoms of depression and psychovegetative disturbances. Doses were determined individually by the responsible physician. Relief of symptoms, tolerability and satisfaction with the therapy was assessed by physicians and parents by questionnaires. Physicians rating of effectiveness as 'good' or 'excellent' was 72% after 2 weeks, 97% after 4 weeks and 100% after 6 weeks. The ratings by parents were very similar [Hübner 2001].

*Clinical studies and post-marketing surveillance studies in **mild to moderate depression** performed with hydroethanolic extracts (ethanol 80%)*

The DER of the extract used in the following studies was 3-6:1

In a post-marketing surveillance study in 4188 patients suffering from psychovegetative disorders, depressive states, anxiety and/or nervous unrest, the effect of an extract (900 mg per day p.o.) was studied over 12 weeks. The HAMD score decreased from an average of 15.8 to 9.5 after 4 weeks and finally to 4.6. The percentage of responders (decrease in HAMD-score ≥ 50%) was about 78%. In the subgroup of patients with a HAMD-baseline score of ≥ 17 the percentage of responders was about 77%; of this group, two-thirds of the patients older than 65 years and two-thirds of those with an illness duration > 1 year experienced an improvement. The efficacy of the extract was rated "very good" or "good" by 81.1% of the doctors and 76.6% of the patients. The tolerability was rated "very good" or "good" by 95.6% of the doctors and 92.4% of the patients [Demling 2004].

In a double-blind, randomised, placebo-controlled, prospective study, an extract at a dose of 900 mg daily was compared to placebo. Out-patients (n=140) suffering from moderate MDD according to ICD-10 (F32.1 or F33.1) and DSM-IV with a total 17-item HAMD score of 20 to 24 were included. Following a single-blind placebo run-in period of 7 days, the patients were randomised to the extract or placebo for 6 weeks. While the total HAMD score decreased in both groups compared to baseline, from 22.8±1.1 to 11.8±4.4 in the verum group and from 22.6±1.2 to 19.2±3.8 in the placebo group, there was a significantly greater reduction in the verum group ($p<0.001$). Comparable differences in favour of the extract were revealed by the D-S and CGI scales and a global efficacy assessment [Uebelhack 2004].

Patients (n=388) suffering from a first episode or recurrent MDD defined by ICD-10 (F32.1 or F33.1) and DSM-IV (major depressive (296.2 x) and recurrent major depression (296.3 x) with a total 17-item HAMD score of 20-24 received 900 mg extract or 20 mg CIT or placebo daily for 6 weeks. From baseline values of 21.9 ± 1.2 points (extract), 21.8 ± 1.2 points (CIT) and 22.0 ± 1.2 points (placebo), the total HAMD scores were reduced to 10.3 ± 6.4 (extract), 10.3 ± 6.4 (CIT) and 13.0 ± 6.9 (placebo). A therapeutic equivalence of the extract to CIT and superiority over placebo ($p<0.0001$) were demonstrated. At the end of treatment, 54.2% (extract, $p<0.003$ vs. placebo), 55.9% (CIT, $p<0.001$ vs. placebo) and 39.2% (placebo) of the patients were assessed as therapy responders (HAMD ≤10). No significant difference in the responder rate was observed between both active treatments. Regarding changes in D-S and CGI scales, the extract was not significantly different from CIT, but was significantly ($p<0.001$) superior to placebo [Gastpar 2006].

In the above study, 188 patients were classified as responders to treatment, as defined by a final HAMD score of ≤10 at the end of the trial. Duration of response and occurrence of relapse/recurrence was measured in 154 patients by re-analysing data from the clinical trial. In total, 30 (19.5%) of the responders were diagnosed with a relapse. The number of patients exhibiting relapse was the highest in the CIT group (14 of 54), whereas

patients who were treated with the extract showed the lowest relapse rate (8/54); patients from the placebo group showed a relapse rate of 8/46. No difference in the severity of relapse was observed. The duration of response was longest for the extract group (1817 days), intermediate for the CIT group (1755 days) and shortest for the placebo group (802 days) [Singer 2011].

A controlled observational study with a follow-up duration of six months involved 514 patients with moderate depression (intention-to-treat group). Of the included patients, 362 (70.4%) received an extract and 152 (29.6%) were treated with an SSRI, in most cases CIT. Outcome measures were efficacy and tolerability of treatment under day-to-day conditions. Efficacy was comparable between the groups, assessed by physicians as "good" to "very good" in 86.1% of extract group patients and 87.9% of SSRI group patients. The extract was significantly ($p<0.001$) better tolerated than the SSRIs, with tolerability judged as "very good" to "good" in 97.0% of extract patients compared to 82.1% of SSRI patients [Kresimon 2012].

Clinical studies and post-marketing surveillance studies in ***mild to moderate depression*** *performed with hydroethanolic extracts (ethanol 60%)*

The DER of the extract used in the following studies was 5-7:1

In an uncontrolled drug surveillance study, 2404 patients (mean age 50 years) with depressive symptoms of varying severity were treated with an extract at an average dose of 120-180 mg twice daily for an average treatment period of 5 weeks. Typical symptoms of depression decreased in both frequency and intensity, the response rates were 73% for depressed mood, 81% for loss of interest, 66% for reduced self-esteem and self-confidence, 69% for lack of concentration and 68% for anxiety. Overall, 90% of patients responded to treatment and more than 50% noticed an improvement in symptoms after 2 weeks of therapy. Using the CGI scale, efficacy was rated as good or very good in 77% of patients (about 80% for patients under 54 years, decreasing to 73% with older patients). A correlation was evident between severity of condition and response rates (82% for mild, 79% for moderate, 64% for marked severity) [Schakau 1996].

In a multicentre, randomised, double-blind, three-armed study, 263 patients (mean age 47 years) with moderate depression (ICD-10: F32.1 and F33.1), and a mean initial total 17-item HAMD score of 22.6 points, were allocated daily treatment for 8 weeks with either 3 × 350 mg of an extract (0.2-0.3% total hypericin, 2-3% hyperforin), 100 mg of IMI (50 mg + 25 mg + 25 mg) or placebo. The extract reduced HAMD scores more effectively than placebo (mean decrease after 6 weeks of 13.4 versus 10.3). Mean decreases from baseline at 8 weeks were similar for the extract and IMI (15.4 versus 14.2). More patients receiving the extract had ≥ 50% improvement in HAMD scores than patients receiving placebo ($p=0.027$); whereas the proportions did not differ between the extract and IMI groups ($p=0.14$). Comparable results were found for HAMA and CGI scores, and were most pronounced for the Zung self-rating depression score. Quality of life, as measured by the SF-36 standardised mental component scale, was improved to a greater extent by both active treatments than by placebo (40.5% by the extract, 30% by IMI). Using the SF-36 physical component scale, compared with placebo quality of life was markedly improved only by the extract (74.5% as compared to 23% by IMI) [Philipp 1999].

The effects of 2 × 400 mg of an extract or 2 × 10 mg of FLU daily were compared in a 6 week randomised, double-blind, comparative trial in 149 elderly outpatients (mean age 69 years) suffering from a first episode of mild or moderate depression (ICD-10: F32.0 or F32.1). During treatment, average HAMD scores decreased from 16.6 to 7.9 in the extract group and from 17.2 to 8.1 in the FLU group. The efficacy of the two medications was found to be equivalent in both mild and moderate depressive episodes. Responder rates (total HAMD score < 10 or a reduction of at least 50% from initial score) were 71% in the extract group and 72% in the fluoxetine group [Harrer 1999].

In a further uncontrolled drug monitoring study, 607 patients (mean age 50.5 years) with depressive symptoms were treated once or twice daily for 6 weeks with 425 mg of an extract. The initial mean 17-item HAMD score of 19.2 decreased to 7.4 points by the end of the treatment. Similar results were obtained for the D-S scale score decreasing from 22.2 to 8.9 points. Core symptoms such as low mood, lack of energy and concentration improved by 50% [Mueller 1998].

The DER of the extract used in the following studies was 2.5-5:1.

In a multicentre, randomised, double-blind, placebo-controlled study, 147 patients (mean age 49 years) suffering from mild or moderate depression in accordance with DSM-IV criteria, and with initial total 17-item HAMD scores ≥ 17, were treated daily for 6 weeks with placebo or 3 × 300 mg of one of two extracts (5% hyperforin or 0.5% hyperforin). The average HAMD score at baseline was 20.8. At the end of the study, the group receiving the extract with 5% hyperforin had the largest reduction in HAMD score from baseline (10.3 ± 4.6), followed by the group with the lower content of hyperforin (8.5 ± 6.1) and the placebo group (7.9 ± 5.2). The proportions of responders were 49% in the 5% hyperforin group, 39% in the 0.5% hyperforin group and 33% in the placebo group. HAMD score reduction was significantly superior to placebo only in the 5% hyperforin group ($p=0.004$). Results were similar for other outcome measures (CGI and D-S depression scales) [Laakmann 1998].

In a multicentre, randomised, double-blind, placebo-controlled study, 72 patients with mild to moderate MDD (in accordance with DSM-IV) were given either a daily dose of 3 × 300 mg of an extract (5% hyperforin) or placebo for 6 weeks. Group differences in favour of the verum were significant after 4 weeks ($p=0.011$) and 6 weeks ($p<0.001$). Average 17-item HAMD scores decreased from 19.7 to 8.9 after verum and from 20.1 to 14.4 after placebo. Analysis of responders showed a reduction of at least 50% from HAMD baseline scores in 62.2% of the verum group and 42.9% of the placebo group ($p=0.10$). The difference was larger when '60%-responders' were considered (51.4% vs. 17.1%) [Kalb 2001].

In a multicentre, observational study, the effectiveness of an extract was examined in 2166 patients (average age 50 years) suffering from mild to moderate depression. Most of the patients were suffering from a first episode, with one third suffering from recurrent depression. Initially, 1385 patients took 600 mg and 781 patients 1200 mg of the extract daily. Moderate depression at baseline (based on CGI) was reduced to less than "mild" after an average observation time of seven weeks in 83.7% of patients at 600 mg and 88.6% at 1200 mg. The improvement in symptoms as measured by 17-item HAMD scores was of clinical relevance [Rychlik 2001].

The DER of the extract used in the following studies was 3.5-6:1

In an observational study, 1778 patients with depressive symptoms received an extract (425 – 1700 mg) for 12 weeks. At inclusion, the mean daily dose was 822.5 mg and at the last visit 754.4 mg. At the last visit, the ICD-10 sum score had

decreased by 63.1% and the proportion of patients described as 'normal to mildly ill' (GCI-S) had increased from 21.6% to 72.4%. Regarding the GCI-I, 77% of the patients had improved 'very much' or 'much', consistent with their self-assessment (76%). Lower age and shorter duration of the disorder were associated with significantly better outcomes [Melzer 2010].

Clinical studies and post-marketing surveillance studies in ***mild to moderate depression*** *performed with hydroethanolic extracts (50% ethanol)*

The DER of the extract used in the following studies was 5-8:1

In a randomised, double-blind, multicentre trial, 97 patients (mean age 43 years) with a moderate depressive episode (ICD-10, F32.1) received 2 × 100-120 mg of an extract or placebo daily for 6 weeks. Initial HAMD scores dropped from 24.6 to 7.9 points in the verum group and from 22.6 to 10.3 in the placebo group (p=0.019). Responder rates (total score at the endpoint < 10 or decrease of at least 50% from initial score) were 79% and 56% respectively [Witte 1995].

The DER of the extract used in the following studies was 4-7:1

In an open, uncontrolled, multicentre drug surveillance study, 170 patients (mean age 49 years) with masked, mild, moderately severe or severe depression received 2 × 250 mg of an extract (0.2% total hypericin) daily for an average period of 66 days. HAMD scores were evaluated in 84 patients. Treatment response was satisfactory in patients with masked, mild and moderate depression, but not in those with severe depression. Typical depressive symptoms decreased by 40% in the first group but only by 12.5% in the subgroup with severe depression. In the group of patients whose HAMD scores were evaluated, the mean initial score of 36.3 dropped to 27.2 by the end of treatment. In a further subgroup analysis, severe cases did not significantly benefit from the treatment (p=0.46). Global efficacy, assessed in 94 of the patients, was rated as good or very good in 78%, slight in 3% and insufficient in 19% [Meier 1997].

In a randomised, double-blind, multicentre trial with 162 patients (mean age 43 years) suffering from mild to moderate depression (ICD-10: F32.0, F32.1) the treatment was either 2 × 250 mg of an extract (0.2% total hypericin) or placebo daily for 6 weeks. Over the course of the study 21-item HAMD scores dropped from 20.1 to 10.5 in the verum group and from 18.8 to 17.9 in the placebo group (p<0.001). Responder rates (defined as reduction in HAMD ≥ 50% and/or actual HAMD score of ≤10) were 56% and 15% respectively [Schrader 1998].

In another randomised, double-blind, multicentre study, involving 240 patients (mean age 47 years) with mild to moderate depression (ICD-10: F32.0, F32.1) and 21-item HAMD scores of 16 to 24 (mean initial score 19.6), the treatment was either 2 × 250 mg of an extract (0.2% total hypericin) or 1 × 20 mg of FLU daily for 6 weeks. After 6 weeks, HAMD scores dropped significantly from 19.65 to 11.5 in the extract group compared to 19.5 to 12.2 in the FLU group (p<0.09). The extract was superior to fluoxetine with respect to responder rates (defined as reduction in HAMD ≥ 50% and/or actual HAMD score of ≤ 10) (p=0.005; 60% for the extract and 40% for fluoxetine) and CGI item 1 score (p<0.03) [Schrader 2000].

In a randomised, double-blind, multicentre study, 324 outpatients (mean age 46 years) with mild to moderate depression (ICD-10: F32.0, F32.1, F33.0, F33.1) were treated daily for 6 weeks with either 2 × 250 mg of an extract (0.2% total hypericins) or 2 × 75 mg of IMI. The 17-item HAMD scores decreased from 22.4 to 12.0 in the extract group and from 22.1 to 12.75 in the IMI group. None of the differences between treatment groups reached significance, except for a difference in HAMD anxiety-somatisation subscale scores in favour of the extract (p=0.03). Responder rates, defined by a drop of at least 50% of the baseline HAMD values, were 43% in the extract group and 40% in the IMI group [Woelk 2000b].

An observational study in 11,296 patients, diagnosed in most cases with mild to moderate depression, was performed using an extract. After eight weeks of treatment symptom scores (modified HAMD) were improved by 60%. Efficacy was rated as "good" to "very good"by the physicians in 80.7% of cases. Mild adverse effects were reported in only 0.2% of cases, and did not show a systematic pattern [Volz 2000].

A 12-week observational study assessed the effects on quality of life and safety of a once daily dosing scheme (dose not specified) of an extract in 4337 patients with mild to moderate depression. Quality of life was assessed using the SF-12 symptom score, and showed a significant improvement, reaching average values of the normal population. Only four patients (0.15%) reported mild adverse events [Rudolf 2004].

A controlled, double-blind, multicentre study aimed to demonstrate the non-inferiority of an extract (612 mg once daily; n = 123) compared to SERT (50 mg; n = 118) in patients with a diagnosis of moderate depressive disorder (according to ICD-10 criteria). The initial study duration was 12 weeks, followed by an additional 12 weeks of treatment for 81 participants in the extract group and 80 participants in the SERT group. As measured by the primary efficacy variable, the 17-item HAMD total score at the end of the first 12 weeks of treatment, the extract was found not to be inferior to SERT (p<0.0001) [Gastpar 2005].

The long-term safety and effects of an extract were evaluated in 440 out-patients suffering from mild to moderate depression according to ICD-10 in an open multicentre study. Patients were treated for up to 1 year with 500 mg of the extract per day. Mean HAMD scores decreased from 20.58 at baseline to 12.07 at week 26 and to 11.18 at week 52. Mean CGI scores decreased from 3.99 to 2.20 at week 26 and 2.19 at week 52 [Brattström 2009].

Clinical studies performed with tinctures (49-50% ethanol)

In a randomised, double-blind, placebo-controlled study, 60 depressive patients (mean age 49 years) were treated daily for 6 weeks with 3 × 1.5 mL of a tincture (50% ethanol, daily dose equivalent to 0.9 mg of total hypericins) or placebo. Using a self-developed, graded scale with 52 symptoms, a considerable reduction of 61.4% in the total score for the verum group compared to only 15.8% for the placebo group. Responder rates, defined by the investigators' assessment of good or very good improvement, were 63% in the verum group and 10% in the placebo group [Hoffmann 1979].

In another randomised, double-blind, placebo-controlled study, 49 patients (mean age 42.3 years) with mild to moderate depressive symptoms were treated with 3 × 1 mL of a tincture (49% ethanol, 0.4:1) or placebo daily for 4 weeks. In the placebo group the mean number of symptoms increased from 24 to 29.6 after 4 weeks, whereas patients treated with the tincture experienced an average reduction from 22.9 to 16.4 symptoms (p<0.05) [Schlich 1987].

In a two-centre, double-blind, placebo-controlled study, 40 patients (mean age 47 years) with depressive symptoms received daily either 3 × 1.5 mL of a tincture (49% ethanol, 0.4:1) or placebo. After 4 weeks the initial HAMD total scores had

decreased from 29.25 to 9.75 in the verum group (n = 16) and from 29.5 to 19.5 in the placebo group (n = 12). Responder rates (a reduction of at least 50% from baseline HAMD scores or an endpoint score of < 10) were 62.5% in the verum group and 33.3% in the placebo group [Schmidt 1989].

In a multicentre, double-blind, placebo-controlled study, 120 patients (mean age 48.5 years) suffering from mild depressive symptoms (ICD-09: 304.4 and 309.9; initial HAMD scores of 16-20) were treated with 3 × 1.5 mL of a tincture (49% ethanol; 0.25 mg of total hypericins per mL) or placebo daily for 6 weeks. Results from 116 patients showed a marked reduction of 57.9% in HAMD total scores in the verum group compared to only 18.1% in the placebo group. Comparable results were obtained using the HAMA and D-S scale. Responder rates (total HAMD score < 10 at endpoint or a drop of at least 50% from baseline scores) were 65.9% after verum and 25% after placebo [Harrer 1991].

In another randomised, double-blind, placebo-controlled, multicentre study, 88 patients (mean age 43.3 years) suffering from mild to moderate depressive symptoms (ICD-09: 300.4; HAMD score at least 16) were treated with either 3 × 1.5 mL of a tincture (49% ethanol; 0.25 mg of total hypericins per mL) or placebo daily for 4 weeks. HAMD scores decreased from 17.8 to 5.2 in the verum group ($p<0.001$) and from 17.3 to 15.5 in the placebo group. Responder rates (defined as reduction in HAMD ≥ 50% and/or actual HAMD score of ≤10) were 70.7% after verum and only 7.1% after placebo [Quandt 1993].

In other studies, the same preparation at the same daily dosage was compared to 50 mg of IMI daily in 30 patients with depressive states after surgery [Werth 1989], and to 6 mg of bromazepam daily in 80 patients suffering from psychogenic depressive symptoms [Kugler 1990]. Comparable efficacy results for the tincture and the reference medication were reported in both studies.

In an open, comparative study, patients (mean age 52.9 years) with climacteric complaints were treated daily with either 3 × 1.5 mL of a tincture (50% ethanol; daily dose equivalent to 0.9 mg of total hypericins; n = 40) or 3 × 2 mg of diazepam (n = 20). In the investigator's judgement, 77.5% of patients treated with the tincture and 50% of patients treated with diazepam were fully remitted after 3 months. The score for the depression component of the HAMA scale dropped from 2.80 to 1.73 after 1 month and to 0.79 after 3 months in the tincture group, and from 2.95 to 1.86 after 3 months in the diazepam group. Similar results were obtained from D-S score evaluation [Warnecke 1986].

Clinical studies performed with other preparations

In a randomised, double-blind, multicentre, three-armed study involving 348 outpatients suffering from mild to moderate depression, diagnosed in accordance with ICD-10, three preparations containing a dry extract (DER 4-5:1; standardised to 0.17 mg, 0.33 mg or 1 mg of total hypericins per day) were assessed for 6 weeks. The highest daily dose corresponded to 3 × 60 mg of the extract. Initial average HAMD scores of 16-17 dropped to 8-9 after 6 weeks in all three groups. Response rates (defined as reduction in HAMD ≥ 50% and/ or actual HAMD score of ≤10) were 62%, 65% and 68% respectively. No significant differences between the three groups were detected [Lenoir 1999].

In a randomised, double-blind, crossover study, the anti-depressant effect of a tea taken twice daily (at least 0.28 mg of total hypericins per day) was assessed in 19 patients (at least 60 years old) and compared to milfoil tea (*Achillea millefolium*) as a control. Each treatment period lasted 14 days, separated by a wash-out period of 3 days. Thirteen patients reported better results with St. John's wort tea, while five patients had better results with milfoil tea and one patient showed no difference. The pilot study indicated a trend towards a better mood in patients treated with St. John's wort tea ($p=0.06$) [Engesser 1996].

In a randomised, controlled, double-blind study, 70 patients (mean age 49.7 years) with mild to moderate depression received twice daily for 6 weeks either an unspecified extract (150 mg) or FLU (20 mg). Both treatments significantly ($p<0.001$) decreased the total HAMD score (extract: 50%; FLU: 58%) and the D-S scale (42% and 52% respectively). The extract achieved 83% (HAMD) and 78% (D-S) of the effects of fluoxetine, with the differences not significant ($p=0.23$). Assessments by physicians and patients indicated considerable improvement with no differences between the treatments [Behnke 2002].

In a double-blind, randomised trial, treatment for 12 weeks with an unspecified extract (900 to 1800 mg/day) was compared with SERT (50 to 100 mg/day) in 87 men and women with major depression and an initial HAMD score of ≥ 16. No differences in the change to mean HAMD and BDI scores (using intention-to-treat analysis), with and without adjustment for baseline demographic characteristics, were observed between the two groups at 12 weeks. Significantly ($p<0.05$) more side effects were reported in the SERT group than in the extract group at 2 and 4 weeks' follow up [van Gurp 2002].

A pilot study examined the efficacy, safety, tolerability, and pharmacodynamics of an unspecified extract in the treatment of 33 outpatient youths (6 to 16 years; mean (SD) age 10.5 (2.9)) diagnosed with major depressive disorder (DSM-IV). In this 8-week, prospective, open-label study, patients were initially prescribed 150 mg of the extract three times daily. At the end of week 4, in the 22 patients who did not meet the *a priori* response criteria, the dose was increased to 300 mg three times daily. Twenty-five of the patients met the response criteria (Children's Depression Rating Scale – Revised (CDRS-R) score ≤ 28 and a CGI-S score ≤ 2) after 8 weeks of treatment. Overall, the extract was well tolerated [Findling 2003].

An uncontrolled study evaluated the efficacy of treatment for 8 weeks with an unspecified extract (0.3% hypericin, 3% hyperforin; 3 × 300 mg daily) in 26 adolescents with MDD (12–17 years, mean age 14.8 years). Of the 11 patients completing the study, 9 (82%) showed significant clinical improvement based on CGI change scores. Of the 15 patients (58%) who did not complete the study, 8 were non-compliant and 7 were discontinued because of persisting or worsening depression [Simeon 2005].

An unspecified extract was compared with FLU in a randomised, double-blind trial in 72 patients with mild to moderate depression. Patients were treated for 8 weeks with either a standardised extract (not futher specified; 900 mg/day), FLU (20 mg/day) or placebo. Intention-to-treat analysis showed no differences in changes to the mean scores of HAMD-21, Montgomery-Asberg Rating Scale and CGI between the three groups. Patients receiving the extract had the lowest remission rates (12%, $p=0.016$) compared to FLU (34.6%) and placebo (45%) [Moreno 2005].

In a three-arm, randomised clinical trial, the effects of treatment for 12 weeks with an unspecified extract (810 mg/day) were compared with CIT (20 mg/day) and placebo in 81 patients with minor depression or milder forms of MDD (with at least

of two to four symptoms of major depression according to DSM-IV). Additional criteria included HAMD scores between 10 and 17, a GAF score of less than 70, and either an MOS Social Functioning score of 75% or less or an MOS Emotional Role Functioning score of 67% or less. Due to a high placebo response on all outcome measures, neither the extract nor CIT differed from placebo [Rapaport 2011].

Clinical studies - other conditions

Attention-deficit hyperactivity disorder (ADHD)
An unspecified standardised extract (0.3% hypericin) was administered in a randomised, double-blind, placebo-controlled trial to children aged 6 to 17 years who met DSM IV criteria for ADHD. After a placebo run-in phase of 1 week, participants were randomly assigned to receive either placebo or 300 mg of the extract 3 times daily for 8 weeks. No significant difference was found in the change in ADHD Rating Scale-IV scores from baseline to week 8 between the treatment and placebo groups: inattentiveness improved by 2.6 points (95% confidence interval [CI], -4.6 to -0.6 points) with the extract vs. 3.2 points (95% CI, -5.7 to -0.8 points) with placebo (p=0.68) and hyperactivity improved by 1.8 points (95% CI, -3.7 to 0.1 points) with the extract vs. 2.0 points (95% CI, -4.1 to 0.1 points) with placebo (p=0.89). There was also no significant difference in the percentage of participants who met criteria for improvement (score ≤2) on the CGI Improvement Scale. No difference between groups was found for adverse effects [Weber 2008].

An unspecified extract was given at a daily oral dose of 30 mg for 4 weeks in an open trial to three 14-16-year-old male psychiatric outpatients with ADHD. After this treatment, patients received a placebo for a further 4 weeks. Assessed by the Conner Scale and by the Continuous Performance Test, at baseline and at the end of each treatment, patients' mean scores improved for Conners' hyperactivity, inattention and immaturity factors [Niederhofer 2010].

Somatoform disorder
The efficacy of a methanolic (80%) extract was studied in a multicentre, double-blind, placebo-controlled trial in 151 out-patients suffering from somatisation disorder (ICD-10: F45.0), undifferentiated somatoform disorder (F45.1), or somatoform autonomic dysfunctions (F45.3). Patients received the extract (600 mg/day p.o.) or placebo for 6 weeks. The extract demonstrated significantly (p=0.001) greater efficacy in the primary outcome criterion Hamilton Anxiety Scale, subfactor somatic anxiety (HAMA-SOM) [decrease from 15.39 to 6.64 in the extract group and from 15.55 to 11.97 in the placebo group]. The extract was also significantly more effective as measured by the CGI (p=0.006), HAMA-total score (p=0.0001), subscore psychic anxiety (p=0.001), HAMD (p=0.001), Self-Report Symptom Inventory 90 items – revised (SCL-90-R; p=0.001), and SCL-90-R, subscore somatic anxiety (SCL-90-R-Som; p=0.001). Tolerability of the extract was excellent [Volz 2002].

In a prospective, randomised, double-blind, placebo-controlled, parallel group study, outpatients with somatisation disorder (ICD-10 F45.0), undifferentiated somatoform disorder (F45.1) and somatoform autonomic dysfunction (F45.3), received either 300 mg of a methanolic (80%) extract twice daily or placebo for 6 weeks. Somatoform Disorders Screening Instrument-7 days (SOMS-7), somatic subscore of the HAMA, SCL-90-R, subscores "improvement" and "efficacy" of the CGI, and the global judgment of efficacy by the patient were measured. In the intention-to-treat population, for each of these measures as well as for the combined test, significant superiority of treatment over placebo was demonstrated (p<0.0001). Of the treated patients, 45.4% were classified as responders compared with 20.9% for placebo (p=0.0006). Tolerability of the extract treatment was equivalent to placebo [Müller 2004].

Social phobia
Forty patients with generalised social anxiety disorder were randomised to 12 weeks of treatment with a flexible dose (600-1800 mg) of a methanolic (80%) extract or placebo. Subjects with co-morbid depression (HAMD>16) were excluded. No significant difference (p=0.27) in mean change on the Liebowitz Social Anxiety Scale was observed between the extract (11.4) and placebo (13.2) [Kobak 2005b].

Obsessive-compulsive disorder
In a randomised, double-blind, placebo-controlled, parallel group study sixty subjects with obsessive-compulsive disorder (OCD) were randomised to 12 weeks of treatment with a methanolic (80%) extract in a flexible-dose schedule (600-1800 mg/day p.o.) or placebo. The mean change in the Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) with the extract (3.43) as well as Y-BOCS subscales were not significantly different from the mean change with placebo (3.60). The percentage of patients rated as 'much' or 'very much' improved at endpoint was not significantly different between the extract treatment (17.9%) and placebo (16.7%) (p=0.905) [Kobak 2005a].

Autism
An unspecified extract was assessed in an open trial in three male patients with autistic disorder. Parent and mentor ratings on the Aberrant Behaviour Checklist, irritability, stereotypy and inappropriate speech factors improved slightly during treatment. Ratings such as the Psychiatric Rating Scale Autism, Anger and Speech Deviance factors, Global Assessment Scale and CGI efficacy did not improve significantly [Niederhofer 2009].

Menopause
Women aged from 40 to 65 years (n=47) experiencing hot flushes (≥ 3 per day, Heart and Estrogen/Progestin Replacement Study scale) were randomly assigned to receive an ethanolic extract (300 mg 3 times daily) or placebo. After 12 weeks of treatment, a non-significant difference favouring the extract group was observed in the daily hot flush frequency (extract -2.3 ± 3.6; placebo -1.0 ± 2.2; p=0.11) and the hot flush score (3.8 ± 8.3 and -1.8 ± 6.5 respectively; p=0.10). After 3 months of treatment, the women in the extract group reported significantly better quality of life (p=0.01) and significantly less sleep problems (p=0.05) compared to placebo [Al-Akoum 2009].

Women (n=100, mean age 50.4 years) with climacteric complaints according to the Blatt-Kupperman Index were treated with 20 drops 3 times per day of an extract (containing 0.2 mg/ml hypericin; not further specified) or placebo for 8 weeks. Although both groups responded to the interventions, the differences between the groups in frequency, duration, and severity of hot flushes were significant (p<0.05). The duration of hot flushes was significantly decreased in the extract group compared with placebo in week 8 (p<0.001), but not in week 4 (p=0.085). The decrease in frequency of hot flushes was significantly greater in the extract group compared to placebo in weeks 4 and 8 (p=0.05 and p<0.001 respectively). The decrease in the severity of flushes was more evident in the extract group in weeks 4 and 8 (p=0.004 and p<0.001 respectively) [Abdali 2010].

St. John's wort was found to be significantly superior to placebo (standard mean difference = -1.08; 95% confidence interval: 1.38 to -0.77) in a meta-analysis comparing the efficacy and adverse events for extracts of St. John's wort, combination products and placebo in menopausal women [Liu 2013].

Premenstrual symptoms (PMS)
Women with premenstrual syndrome (n=19) took a methanolic (80%) extract for two complete menstrual cycles (300 mg extract per day standardised to 900 µg hypericin). The Hospital Anxiety and Depression (HAD) scale and a modified Social Adjustment Scale were measured at baseline and after one and two menstrual cycles. There were significant ($p<0.05$) reductions in all outcome measures. The degree of improvement in overall premenstrual syndrome scores between baseline and the end of the trial was 51%, with over two-thirds of participants demonstrating at least a 50% decrease in symptom severity [Stevinson 2000].

In a randomised, double-blind, placebo-controlled, crossover study 36 women (18-45 years) with regular menstrual cycles (25-35 days), who were prospectively diagnosed with mild PMS, underwent a two-cycle placebo run-in phase. They then received either 900 mg/day of a methanolic extract (80%; standardised to 0.18% hypericin; 3.38% hyperforin) or placebo for two menstrual cycles. After a placebo wash-out month the treatments were crossed over for two further cycles. The extract was superior to placebo in improving physical and behavioural symptoms of PMS ($p<0.05$) but not superior for mood- and pain-related symptoms. Plasma hormone (FSH, LH, E_2, progesterone, PRL and testosterone) and cytokine (IL-1β, IL-6, IL-8, IFN-γ and TNF-α) levels, as well as weekly reports of anxiety, depression, aggression and impulsivity, did not differ significantly between treatments ($p>0.05$) [Canning 2010].

Patients with PMS (n=170) received an unspecified extract (two 680 µg "hypericin tablets" per day) or placebo for 8 weeks. Treatment with the extract resulted in significantly lower PMS scores compared with baseline ($p<0.001$) and control ($p<0.001$). The biggest improvements in score occurred for crying (71%) and depression (52%). The drop-out rate due to adverse events was higher in the extract group ($p=0.02$), although there were no significant differences in adverse events. Symptom ratings were reduced by 40% after extract treatment [Ghazanfarpour 2011].

Irritable bowel syndrome (IBS)
An unspecified extract was given for 8 weeks at an oral dose of 900 mg/day to 30 female patients with IBS. Patients and 20 healthy controls underwent serial autonomic nervous system function tests before and after 8 weeks of treatment. Five-minute-short-time heart rate variability spectral analysis was assessed at rest and during three different types of stress test (somatic, psychological and visceral stimuli). HAMD and HAMA scores were used to measure depression and anxiety; and patients completed a gastrointestinal (GI) symptom diary once daily during the 2 weeks before therapy and for 2 weeks up to the last scheduled therapy session. Compared to the untreated control group, the IBS-group had higher initial scores in the HAMA and HAMD (both $p<0.01$); with these scores significantly decreasing post-treatment ($p<0.05$). Compared to the resting state, the IBS group exhibited significant increases in the low frequency band/high frequency band ratio (L/H) during each period of stress testing ($p<0.01$). Treatment with the extract for 8 weeks led to a significantly decreased ($p<0.05$) L/H response to the various stressors when compared to baseline. GI symptoms of IBS were also significantly ($p<0.05$) relieved by the treatment [Wan 2010].

In a randomised, double-blind, placebo-controlled trial, 70 patients with IBS received either an unspecified extract at an oral dose of 900 mg or placebo for 12 weeks. Of the patients, 29% had constipation dominated IBS (C-IBS), 37% diarrhoea dominated IBS (D-IBS), and 31% had mixed IBS. Both groups reported decreases in overall bowel symptom score from baseline, though the placebo arm had significantly lower scores at 12 weeks ($p=0.03$) compared with the extract. The percentage of patients with adequate relief was also significantly higher in the placebo group ($p=0.02$) [Saito 2010].

Burning mouth syndrome (BMS)
A double-blind, randomised, placebo-controlled, single-centre study evaluated patients with BMS (n=39) receiving oral doses (300 mg, 3 times daily) of an unspecified extract (hypericin 0.31%, hyperforin 3.0%) or placebo for 12 weeks. Burning pain, measured using a visual analogue scale (VAS), was only slightly more improved in the extract treated group [Sardella 2008].

Antiviral effects
In a phase I dose escalation study, the antiviral activity of hypericin was assessed in 19 patients with chronic HCV infection. For 8 weeks, 12 patients received 0.05 mg/kg and 7 patients 0.1 mg/kg hypericin orally once a day. At the end of the 8 week period, plasma HCV RNA level did not change more than 1.0 $\log_{10}$ units. No anti-HCV activity was noted [Jacobson 2001].

Antibacterial effects
In a randomised, placebo-controlled, double-blind study, 21 patients with mild-to-moderate atopic dermatitis (mean SCORAD score 44.5) were treated twice daily for 4 weeks with either a cream containing an unspecified extract (1.5% hyperforin) or placebo (vehicle). The intensity of the eczematous lesions was significantly ($p<0.05$) improved with the verum compared to the vehicle at all clinical visits (days 7, 14, and 28). Skin colonisation with *Staphylococcus aureus* was reduced by verum and placebo treatments, with a trend towards better antibacterial activity for the verum ($p=0.064$) [Schempp 2003a].

Wound healing
In a randomised, double-blind clinical trial (n=144), ointments containing either an oily extract or placebo were applied topically to surgical wounds 3 times daily for 16 days, starting from 24 h after caesarean section. An additional control group remained without any post-operative intervention. Compared to both placebo and control groups, there were significant improvements observed in the extract group for wound healing on the 10th day ($p<0.005$) and scar formation on the 40th day postpartum ($p<0.0001$). Significantly lower pain ($p<0.001$) and pruritus ($p<0.001$) were reported by the treatment group compared with the placebo and control groups on day 40 [Samadi 2010].

Pharmacokinetic properties

Pharmacokinetics in vitro
Variations in the matrices of different extracts affected their absorption and efflux as shown for three extracts submitted to a human intestinal Caco-2 cell transport experiment. Transepithelial transport across the Caco-2 cell monolayer was different for rutin, hyperoside and isoquercitrin founds in extracts when compared to the respective pure compounds. The results clearly revealed that the product matrices affected permeability of the key components [Gao 2010].

The metabolism of hyperforin was characterised using human liver microsomes and CYPs, CYP-selective chemical inhibitors and correlation with CYP-recombinant heterologously expressed CYP enzymes. Among 57 detected metabolites six mono¬hydroxylated compounds (M1-M6) were identified, while others were higher hydroxylated. A combined approach of cDNA-expressed recombinant specific marker activities indicated a central role of the CYP2C and CYP3A families in the metabolism of hyperforin [Hokkanen 2011].

Interactions
After administration of St. John's wort extracts and some of its

components, two types of qualitatively different pharmacokinetic interactions have been observed:

- After acute administration: inhibition of metabolic enzymes and drug transporters [Budzinski 2000; Chaudhary 2006; Dostalek 2011; Dostalek 2005; Foster 2004; Hokkanen 2011; Komoroski 2005; Komoroski 2004; Lee 2006; Obach 2000; Ott 2010; Patel 2004; Schwarz 2011; Tuna 2010; Volak 2010; Wada 2002; Wang 2004a; Weber 2004].

- After subchronic or chronic administration: induction of several enzymes of the cytochrome P450 (CYP) enzyme family (CYP1A1, CYP1A2, CYP3A, CYP2B6, CYP2C8 and CYP2C9, C2C19 and CY2E1) [Chen 2004; Gutmann 2006; Hellum 2009; Komoroski 2005; Komoroski 2004; Krusekopf 2005; Sahi 2009], UDP-glucuronyltransferases (UGT1A1, UGT1A6) [Volak 2010], and several drug efflux transporters from the ATP-binding cassette transporters superfamily (ABC transporters, such as P-glycoprotein (MDR1/ABCB1) or MRP2 (ABCC2), MRP3 (ABCC3)) [Gutmann 2006; Ott 2010; Weber 2004], shown *in vitro* and in animal trials. One mechanism of the interactions is the activation of the pregnane X receptor (PXR) by hyperforin [Moore 2000; Watkins 2003; Wentworth 2000]. The extent of PXR mediated gene induction was proportional to the extent of hyperforin in the extracts [Gödtel-Armbrust 2007; Mueller 2009; Mueller 2006].

Acute administration
Unspecified extracts in methanolic (1%) solution were examined (using microsomal enzyme preparations) for their inhibition towards CYP1A2, CYP2C9, CYP2C19, CYP2D6 and CYP3A4. CYP2D6 was the most sensitive. In the assay of single components, CYP1A2 was inhibited by I3,II8-biapigenin (IC_{50} 3.7 µM) and quercetin (IC_{50} 7.5 µM), CYP2C9 by hyperforin (IC_{50} 4.4 µM), I3,II8-biapigenin (IC_{50} 4.0 µM) and hypericin (IC_{50} 3.4 µM), CYP2C19 by hyperforin (IC_{50} 31 µM), I3,II8-biapigenin (IC_{50} 28 µM) and hypericin (IC_{50} 37 µM), CYP2D6 by hyperforin (IC_{50} 1.6 µM), I3,II8-biapigenin (IC_{50} 5.7 µM), quercetin (IC_{50} 24 µM) and hypericin (IC_{50} 8.5 µM) and CYP3A4 by hyperforin (IC_{50} 2.3 µM), I3,II8-biapigenin (IC_{50} 0.082 µM), quercetin (IC_{50} 22 µM) and hypericin (IC_{50} 8.7 µM) [Obach 2000].

Two ethanolic extracts (A: 50% m/m; B: 60% V/V) and a methanolic extract (C: 80% m/m), as well as hypericin, pseudohypericin, hyperforin, rutin and quercetin, were investigated for their inhibitory effects on carcinogen activation by CYP1A1 using purified enzyme preparations. The extracts potently inhibited CYP1A1 activity (IC_{50} values: 24.0 ± 3.9 µg/mL (A), 8.0 ± 1.0 µg/mL (B), 1.3 ± 0.2 µg/mL (C)). All constituents, except rutin, possessed strong inhibitory potencies with IC_{50} values of 0.5 ± 0.1 µM (hypericin), 8.0 ± 0.1 µM (pseudohypericin), 1.2 ± 0.2 µM (hyperforin) and 1.5 ± 0.2 µM (quercetin) [Schwarz 2003].

The inhibition of human cytochrome P450 enzymes by 18 St. John's wort products containing a wide variety of hyperforin, hypericin and pseudohypericin levels was assessed. The aqueous extracts markedly inhibited cytochrome P450-mediated (CYP 2C9*1, 2C9*2, 2C19, 2D6, 3A4, 3A5 and 3A7) metabolism and inhibited P-glycoprotein (Pgp) activity [Foster 2004].

In MDR1 transfected MDCK cells, hypericin and quercetin at concentrations of 5 to 200 µM showed a significant ($p<0.05$) and dose-dependent inhibition of Pgp-mediated efflux of [^{3}H]-ritonavir and inhibited CYP3A4 activity (hypericin IC_{50} 0.87 µM, quercetin IC_{50} 0.53 µM, kaempferol IC_{50} 0.26 µM) [Patel 2004].

In primary cultures of human hepatocytes, hyperforin at high concentrations of 5 and 10 µM, 1 hour before and along with probe substrate, inhibited CYP3A4 activity. Hypericin had no effect on any of the enzymes tested [Komoroski 2005; Komoroski 2004].

Human hepatocytes were exposed to hyperforin (0.1, 0.5 or 1.5 µM) or rifampin (10 µM) for 48 hours. The medium was then replaced by one containing docetaxel (100 µmol/L). Docetaxel metabolism was characterised by HPLC/MS after 1 hour: metabolism induced by rifampin was 6.8- to 32-fold higher than that in control cultures. Hyperforin induction was dose-dependent and, at maximum, was 2.6- to 7-fold greater than that in controls. CYP3A4 and CYP2C8 were involved in metabolite formation [Komoroski 2005].

Seven flavonoids in St. John's wort and apigenin were screened for their inhibition of recombinant human CYP1B1 and CYP1A1. While myricetin, apigenin, kaempferol, quercetin, amentoflavone, quercitrin and rutin were slightly more selective for CYP1B1 ethoxyresorufin-*O*-deethylase (EROD) inhibition (K_is 0.06 - 5.96 µM) compared to CYP1A1 (K_is 0.20 - 1.6 µM), the differences in K_is for the P450s were not significantly different. Rutin did not inhibit CYP1A1 at concentrations up to 10 µM. In kinetic analyses apigenin and amentoflavone were competitive inhibitors of CYP1B1, while quercetin showed mixed type inhibition. Five flavonoids were studied further for their ability to inhibit TCDD-induced EROD activity in 22Rv1 human prostate cancer cells. 22Rv1 cells expressed constitutive and TCDD-inducible CYP1A1 and CYP1B1 mRNA. The IC_{50} values were similar to those measured for the recombinant CYP1A1 except for amentoflavone. Quercetin (IC_{50}: 4.1 µM), kaempferol (3.8 µM), myricetin (3.0 µM) and apigenin (3.1 µM) caused significant ($p<0.05$) inhibition of EROD activity whereas amentoflavone did not cause inhibition [Chaudhary 2006].

Further investigations confirmed this activity of hyperforin, demonstrating the inhibition of recombinant CYP3A4 (IC50 0.63 µM) [Lee 2006] and of CYP3A4 (IC_{50} 4.4 - 9.6 µM) and CYP2D6 (IC_{50} 7.3 µM) [Hokkanen 2011].

A study of the inhibition of CYP1A1-mediated 2-hydroxylation of oestradiol by a methanolic (80%, V/V) extract and single components found IC_{50} values of 19.5 µg/mL for the extract, 9.8 µM (hypericin), 6.8 µM (pseudohypericin), 3.2 µM (quercetin), 2.2 µM (kaempferol) and 2.2 µM (myricetin). No effects were seen for hyperforin and rutin [Schwarz 2011].

The effects of hyperforin and hypericin on Pgp activity were compared to CyA in the MDR1 over-expressing cell line NIH-3T3-G 185. Both compounds inhibited Pgp activity with an IC_{50} of about 30 µM, which was about 15-fold higher than for ciclosporin (2 µM) [Wang 2004a].

A methanolic (80%, m/m) extract and some of its components were investigated for their effect on Pgp activity in the calcein-AM assay using porcine brain capillary endothelial cells (PBCEC) as a model of the blood-brain barrier as well as in a human MDR1 over-expressing lymphocytic leukaemia-derived cell line VLB 100. The extract inhibited Pgp activity above a concentration of 100 µg/mL ($p<0.05$) in both cell lines. Hyperforin (1 - 10 µM), hypericin (0.03 - 30 µM), quercetin (0.01 - 3 µM), hyperoside (0.3 and 3 µM), rutin (10 µM) and biapigenin (10 and 30 µM) showed significant ($p<0.05$ to $p<0.001$) inhibitory effects on Pgp activity in PBCEC. Amentoflavone activated P-glycoprotein at 3 and 30 µM ($p<0.05$), quercetin and biapigenin activated Pgp at the lowest concentration and inhibited it at the higher concentrations ($p<0.05$). In VLB 100 cells, only 10 µM hyperforin inhibited Pgp ($p<0.01$) [Weber 2004].

A methanolic extract (80%, V/V; 0.1 – 5 µg/mL), hyperforin

(0.1 – 10 µM), hypericin (1 – 50 µM) and quercetin (1 – 50 µM) decreased Pgp transport activity in a dose- and time-dependent manner in PBCEC cells and freshly isolated porcine brain capillaries. The extract and hyperforin directly inhibited Pgp activity, whereas hypericin and quercetin modulated transporter function through a mechanism involving protein kinase C. Quercetin decreased Pgp transport activity at high concentrations (> 10 µM), but increased transporter function at low concentrations (≤10 µM) [Ott 2010].

Hypericin bound and inhibited the major glutathione-S-transferase isoforms GST-α (K_i 0.16 ± 0.02 µM to 1.91 ± 0.21 µM) and GST π (0.55 ± 0.07 µM to 2.46 ± 0.43 µM) [Tuna 2010].

Many UDP-glucuronosyltransferases (UGTs) require phosphorylation by protein kinase C (PKC) for glucuronidation activity. Hypericin, a non-selective PKC inhibitor, inhibited paracetamol glucuronidation by human LS180 cells (IC_{50} = 7.1 ± 0.6 µM). In UGT1A6-infected Sf9 insect cells, hypericin showed a three times more potent inhibition of serotonin glucuronidation in treated whole cells versus cell lysates (IC_{50} = 0.59 ± 0.05 µM) [Volak 2010].

Sub-chronic or chronic administration
LS180 cells were exposed for 72 hours to a methanolic (80%) extract at concentrations of 3 to 300 µg/mL or hyperforin (0.03 to 3 µM) for 3 days. Pgp expression was strongly and dose-dependently induced by the extract (400% increase at 300 µg/mL) and by hyperforin (700% at 3 µM). In Caco-2 cell monolayers, the extract and hyperforin caused a moderate inhibition of Pgp-mediated transport at the highest concentration [Perloff 2001].

LS180 cells were cultured for 48 hours in the presence and absence of three doses of an extract (not further specified) containing 5.61% hyperforin. The extract increased the expression of CYP1A2 in a dose-dependent manner [Karyekar 2002].

In primary cultures of human hepatocytes, after 48 hours incubation with 10 µM hyperforin or rifampin, CYP2B6 expression was induced approximately 4-fold and 15-fold respectively [Goodwin 2001]. Treatment for 96 h resulted in significant ($p<0.05$) increases in mRNA and protein expression, as well as activity of CYP3A4 and CYP2C9, but had no effect on CYP1A2 or CYP2D6 [Komoroski 2005; Komoroski 2004].

HepG2 cells were treated with 0.1% (V/V) of an ethanolic (50% m/m) extract or 0.1 µM hyperforin for 24 hours and RNA was subjected to gene array analysis. The extract and hyperforin affected the expression of genes that mediate metabolism (e.g. CYP3A4, CYP1A1, CYP1A2) and transport exogenous and endogenous compounds (e.g. MRP2), but also of genes involved in energy metabolism, intracellular calcium regulation, cell proliferation and apoptosis [Krusekopf 2005].

An extract and hyperforin but not hypericin increased the expression of Pgp in LS180 cells. Incubation with the extract (20 to 75 µg/mL) for 24 hours led to a dose-dependent increase of MDR1 mRNA expression that exceeded the positive control rifampin (10 µM). Removal of the extract resulted in restoration of basal Pgp levels within 48 hours [Tian 2005].

An ethanolic extract (50% m/m, low hyperforin content) did not affect MDR1 or CYP3A4 expression in LS180 cells. MDR1 expression was significantly ($p<0.01$) up-regulated by hypericin and hyperforin (each 10 µM), and CYP3A4 expression by hypericin, quercitrin and hyperforin [Gutmann 2006].

An ethanolic (60%) extract incubated for 72 hours increased the metabolic activity of CYP2C19 in primary human hepatocytes at 8 and 80 µg/mL ($p<0.05$), while a strong inhibition was observed at 800 µg/mL ($p<0.05$). CYP2E1 activity was increased by 65% ($p<0.05$) at 8 µg/mL and completely inhibited at 800 µg/mL [Hellum 2009].

Pharmacokinetics in animals
After intravenous injection of 350 µg hypericin (about 17.5 mg/kg), peak plasma concentrations in BALB/c mice were 27.8 µg/mL at 10 minutes after administration, which decreased to 0.010 µg/mL after 240 h. The AUC was 285 µg×h/mL, the volume of distribution 12.6 mL and the elimination half-life 38.5 h [Liebes 1991].

After oral administration of [^{14}C]-labelled hypericin and pseudohypericin to 8 female mice, radioactivity was measured in the GI tract and in liver, kidney, muscle, blood and brain. At 1.5 and 6 h after administration, 42% and 19% of the hypericin dose and 69% and 44% of the pseudohypericin dose were detected in the gastrointestinal tract. A proportion of 31% and 11% radioactivity from hypericin was found in muscle after 1.5 and 6 hours. In blood and brain minor quantities were found for both compounds, in the brain 0.7% and 0.6% of the hypericin dose and 0.4% and 0.9% of the pseudohypericin dose at 1.5 and 6 hours respectively [Stock 1991].

After an i.v. administered dose of [^{14}C]-hypericin and [^{14}C]-pseudohypericin in mice, 80% of hypericin and 60% of pseudohypericin was absorbed. Tissue distribution was followed for 2, 4, 6, 8, 24, 72 and 168 hours. The highest tissue concentrations were observed in the lung with over 3.5 µg/g at 4 h, gradually declining to less than 2% of the maximum after 7 days. The concentrations in the tissues were: lung > spleen > liver > blood > kidney > heart > gut > tumour > stomach > skin > muscle > brain [Chung 1994].

The tissue distribution of hypericin (2, 5 or 20 mg/kg i.p.) in DBA/2 mice bearing subcutaneously implanted P388 lymphoma cells resulted in a very high uptake in liver and spleen. Clearance from plasma followed a two-phase exponential decay: a first phase of rapid clearance (half-life 6.9 hours) was followed by a slower phase (half-life 37.9 hours) [Chen 2000].

After oral administration of an ethanolic extract containing 5% hyperforin to rats at 300 mg/kg, maximum plasma levels of 370 ng/mL hyperforin were reached after 3 hours. Estimated half-life and clearance values were 6 hours and 70 mL/min/kg [Biber 1998].

In Sprague-Dawley rats, i.p. administration of 10 mg/kg hyperforin led to plasma levels in the low micromolar range (3 - 5 µM). No hyperforin was detected in the cerebrospinal fluid. At 1 mg/kg the compound was detected in the plasma [Buchholzer 2002].

In a study of the metabolic profile of hyperforin in liver microsomes from male and female Sprague-Dawley rats, with or without induction by phenobarbital or dexamethasone, four major phase I metabolites (19-hydroxyhyperforin, 24 hydroxyhyperforin, 29-hydroxyhyperforin and 34-hydroxyhyperforin) were identified. Results suggested hydroxylation as a major biotransformation of hyperforin in rat liver, mainly by inducible CYP3A and/or CYP2B [Cui 2004].

In male CD rats, procyanidin B_2 increased the oral bioavailability of hypericin by approximately 58% and hyperoside by 34%. The compounds had a different influence on the plasma kinetics of hypericin; median maximal plasma levels of hypericin were detected after 360 min (C_{max} 8.6 ng/mL) for B_2, and after 150 min (C_{max} 8.8 ng/mL) for hyperoside [Butterweck 2003b].

Unspecified extracts (containing either 4.5 or 0.5% hyperforin) and hyperforin dicyclohexylammonium (DCHA) were given to male CD-COBS rats. The 4.5% extract, administered as three i.p. injections in 24 h (3.12-6.25 mg/kg), resulted in dose-related plasma concentrations of hyperforin which were of similar magnitude to those found following the administration of hyperforin DCHA that contained hyperforin at a level equivalent to the 4.5% extract (0.14 and 0.28 mg/kg). Hyperforin was undetectable in rat brain [Cervo 2002].

The determination of plasma levels of hypericin in rats in the presence and absence of procyanidin B_2 or hyperoside showed increased oral bioavailability of hypericin by ca. 58 % procyanidin B_2 and 34% (hyperoside). Median maximal plasma levels of hypericin were detected after 360 min (C_{max}: 8.6 ng/mL) for procyanidin B_2, and after 150 min (C_{max}: 8.8 ng/mL) for hyperoside [Butterweck 2003b].

In mice treated with 15 mg/kg hyperforin, either as the sodium salt or as a 5% extract, average brain tissue concentrations of hyperforin were found to be higher for the sodium salt group (28.8±10.1 ng/g) than the extract group (15.8±10.9 ng/g) [Keller 2003].

After administration of 300 mg/kg p.o. of an ethanolic extract (4.5% hyperforin) to male CD1 mice, hyperforin rapidly reached the systemic circulation, with a C_{max} of approximately 1 µM within 60 min. Blood levels peaked faster (30 minutes) after the application of hyperforin DCHA salt at 18.1 mg/kg. Hyperforin was quantifiable up to 4 - 6 hours post administration. Interestingly, the C_{max} of hyperforin was reduced by approximately 50% after repeated dosing (4 days), correlating with an induction of CYP3A enzymes by hyperforin [Cantoni 2003].

Wistar rats treated with an unspecified extract (1000 mg/kg/day) for 1, 3 or 7 days were administered a single oral dose of midazolam at 10 mg/kg after their final extract dose. Oral clearance of midazolam in the extract treated rats increased time dependently, and was significant ($p<0.01$) after 7 days of treatment with the extract. The midazolam-1-hydroxylation activity in liver microsomes obtained from the extract treated rats was significantly ($p<0.01$) higher than in controls. Linear correlation was observed between oral clearance and midazolam-1-hydroxylation activity in the liver microsomes, suggesting that CYP3A induction in the liver mainly decreased the midazolam concentration in plasma. Immunoblotting revealed that CYP3A was induced within 3 days of extract treatment [Qi 2005].

After single oral doses of an ethanolic extract (60%; 1600 mg/kg) and isoquercitrin (100 mg/kg) to male Sprague Dawley rats, maximal CNS levels for quercetin (340 ng/g) and isorhamnetin/tamarixetin (50 ng/g) were found at 4 h. With repeated daily doses over 8 days the maximal cumulation for quercetin (367 ng/g) occurred after 5 days, whereas isorhamnetin/tamarixetin (640 ng/g) did not reach its maximal cumulation level within the 8-day test period [Paulke 2008].

After administration of an unspecified extract, brain concentrations of amentoflavone were below the limit of quantification. Levels were consistently detected only after i.p. amentoflavone (10 mg/kg), with a mean brain-to-plasma ratio of about 0.02. These concentrations were possibly related to the compound's contribution from residual blood, but in any case are too low to support any interaction with central mechanisms so far tested [Colovic 2008].

In mice treated for a month with an unspecified extract (1500 mg/kg p.o.), hypericin plasma levels were significantly ($p<0.05$) more elevated in females (93 ± 7 ng/mL) than in males (32 ± 3 ng/mL) [Radu 2009].

An experiment investigating fractions of extracts for their antidepressant activity showed that the amount of hypericin needed for significant antidepressant activities in the FST was very high (0.23 mg/kg p.o.), whereas a hypericin-rich fraction was active at doses of 0.028 - 0.16 mg/kg. The fraction contained procyanidin B_2 which increased solubility of hypericin in water, which for hypericin alone was 0.5 µg/mL compared to more than 60 µg/mL with increasing amounts of procyanidin B_2. Higher solubility of hypericin led to increased bioavailability and to increased *in vivo* activity as shown by co-administration of hypericin with procyanidin B_2, thereby increasing the AUC to 160% [Nahrstedt 2010].

Hypericin was administered as an i.v. bolus of 2 mg/kg (n = 3) or 5 mg/kg (n = 1) to male Rhesus monkeys. Plasma and cerebrospinal fluid (CSF; ventricular or lumbar) were sampled prior to administration and at frequent intervals for up to 50 h after administration of the drug. Mean peak plasma concentration of hypericin following the 2 mg/kg dose was 142 ± 45 µM. Elimination of hypericin from plasma was biexponential, with an average distribution half-life of $t_{½,\alpha}$ of 2.8 ± 0.3 h and an average terminal half-life of $t_{½,\beta}$ of 26 ± 14 h. The 2 mg/kg dose was sufficient to maintain plasma concentrations above 10 µM for up to 12 h. No hypericin was detected in the CSF of any animal (LOD 0.1 µM) [Fox 2001].

Interactions

The effects of a co-administered methanolic (80%) extract on the pharmacokinetics of CPT-11 were evaluated in rats pre-treated with the extract (400 mg/kg p.o. for 8 days, 6 mL/kg) or vehicle. CPT-11 was given at a dose of 60 mg/kg per day by i.v. injection via tail vein for 4 consecutive days. Co-administration with the extract significantly ($p<0.05$) altered the pharmacokinetics of both CPT-11 and its metabolite SN-38, and reduced the AUC of the SN-38-glucuronide by 31.2% [Hu 2005].

Swiss Webster mice received either A) an unspecified ethanolic extract for 2 weeks (oral dose not clearly defined); B) the same dose of the extract for 1 week; C) a single dose of the extract; D) no extract; E) hypericin (10 µg); or F) control. All groups received a single dose of procainamide (100 mg/kg p.o.), 24 h after the last extract dose in groups A and B, and 1 h later in group C. The mean procainamide concentration 1 h after administration was highest in group C (11.59 µg/mL) followed by group A (9.92 µg/mL), whereas group B (7.44 µg/mL) and the control group D (7.36 µg/mL) showed comparable values. The concentration in group C was significantly higher than in the control group D ($p=0.03$). *N*-Acetyl procainamide concentrations and estimated half-life of procainamide were comparable between the groups. With hypericin, a significant ($p<0.05$) increase in bioavailability (53%) of procainamide was observed compared to control group F [Dasgupta 2007].

Oral administration of either 150 or 300 mg/day of an unspecified extract for 15 days significantly reduced plasma levels of indinavir. A perfusion study demonstrated that both the small intestine and the liver contributed significantly (both $p<0.05$) to the reduction of indinavir bioavailability. The effect was flow rate-dependent. The small intestine was the major site for the pre-systemic metabolism of indinavir, with or without extract pre-treatment [Ho 2009].

An unspecified extract was given at an oral dose of 400 mg/kg/day to male Wistar rats. Daily administration for 10 days increased respectively the amounts of MRP2, glutathione S-transferase-P (GST-P) and CYP1A2 in the liver to 304%, 252% and 357%

of control levels, the amounts of P-gp and MRP1 were not changed. MRP2 did not appear to increase in the kidney. The increase in the levels of each protein was maximal at 10 days after extract treatment and lasted for at least 30 consecutive days [Shibayama 2004].

Male Sprague-Dawley rats were given a methanolic extract (80%; 1000 mg/kg/day p.o.) for 14 days. On day 15, livers were isolated and perfused in a recirculating system with fexofenadine (FEXO; 2 µg/mL), either alone or following addition of CyA (0.5 µg/mL) 5 min before the application of FEXO. Administration of the extract significantly ($p<0.05$) increased biliary clearance with respect to perfusate, and biliary clearance with respect to the concentration in the liver, by 74% and 71% respectively. This was reversed by the Pgp inhibitor CyA [Turkanovic 2009].

In male Wistar rats i.p. administration of 100 mg/kg/day of a methanolic (80%) extract for 10 days resulted in significant induction of CYP2D2 ($p<0.001$) and CYP3A2 ($p<0.001$) as well as inhibition of CYP2C6 ($p<0.001$) and CYP1A2 ($p<0.001$) activity in an isolated perfused rat model [Dostalek 2011; Dostalek 2005].

A methanolic (80%) extract was given to male Wistar rats for 10 days at an i.p. dose of 100 mg/kg prior to liver preparation. Paracetamol formation from phenacetin (12.5 mg/L) was used as marker for CYP1A2 activity in this isolated perfused liver model. The formation rate of acetaminophen was significantly inhibited by pre-treatment with the extract ($p<0.001$) [Dostalek 2011].

A methanolic (80%) extract at a dose of 300 mg was given orally to four dogs every 24 h for 14 days. A single dose of CyA (5 mg/kg) was given orally 7 days before and 7 and 14 days after start of the extract administration. Control dogs received a single oral dose of CyA (5 mg/kg). The maximum whole-blood concentration and AUC(0-infinity) of the extract group were significantly lower and the CL_{tot}/F and V_d/F were significantly higher (all $p<0.05$) than those in the control group 7 and 14 days after the start of extract administration [Fukunaga 2011].

Pharmacokinetic parameters of etoricoxib (EXB) were significantly altered by oral co-administration to rats of an unspecified extract (25 mg/kg/day) alongside EXB (15 mg/kg/day) for 3 weeks. The steady state peak plasma concentration and terminal half-life were reduced by 32% and 91% respectively, due to a more than 3-fold increase in its apparent clearance which was a concentration and time dependent effect [Radwan 2012].

Rats were given single oral doses of methotrexate (MTX; 5 mg/kg), alone or co-administered with either an unspecified extract (300 or 150 mg/kg) or diclofenac (25 mg/kg). The extract at a dose of 300 mg/kg significantly increased (both $p<0.05$) the AUC(0-t) and C_{max} of MTX, by 163% and 60% respectively, and at 150 mg/kg significantly ($p<0.05$) increased the AUC(0-t) of MTX by 55%. Diclofenac enhanced the C_{max} of MTX by 110% [Yang 2013].

Pharmacokinetics in humans

A study of the bioavailability of hypericin in 2 healthy volunteers after oral administration of an extract (300, 600 and 1200 mg at intervals of 7 days) demonstrated that plasma levels of hypericin were dose-dependent. After ingestion of a single dose of 600 mg of the extract by 12 volunteers, the following parameters were determined for hypericin: t_{max} 2.5 hours, C_{max} 4.3 ng/mL and a plasma half-life of about 6 hours [Weiser 1991].

A methanolic extract was administered orally as single doses of 900, 1800 and 3600 mg, containing 2.81, 5.62 and 11.25 mg of total hypericin. Maximum plasma concentrations of total hypericin, observed about 4 hours after administration, were 0.028, 0.061 and 0.159 mg/L respectively [Brockmöller 1997].

Oral administration to 13 healthy volunteers (at intervals of at least 10 days) of single doses of a methanolic extract containing 250, 750 and 1500 µg of hypericin and 526, 1578 and 3135 µg of pseudohypericin, respectively gave peak plasma levels of 1.3, 7.2 and 16.6 µg/L for hypericin and 3.3, 12.2 and 29.7 µg/L for pseudohypericin. C_{max} and AUC values for the lowest dose were disproportionately lower than those for the higher doses. Lag-times were determined as 1.9 hours for hypericin and 0.4 hours for pseudohypericin. Mean half-lives for absorption, distribution and elimination were 0.6, 6.0 and 43.1 hours after 750 µg of hypericin, and 1.3, 1.4 and 24.8 hours after 1,578 µg of pseudohypericin. After 14 days of oral treatment with 250 µg of hypericin and 526 µg of pseudohypericin, steady state levels of 7.9 µg/L for hypericin and 4.8 µg/L for pseudohypericin were achieved. Kinetic parameters in two subjects after intravenous administration resembled those after oral administration. Hypericin and pseudohypericin were initially distributed into volumes of 4.2 and 5.0 L respectively; at steady state the mean distribution volumes were 19.7 L for hypericin and 39.3 L for pseudohypericin; systemic bioavailability from the methanolic extract was about 14 and 21% respectively [Kerb 1996].

Hypericin levels in serum and skin blister fluid were determined in volunteers after oral administration of a hydromethanolic extract as a single dose of 6 tablets or 3 x 1 tablet daily for 7 days. Each tablet contained 300 mg extract, standardised to 900 µg of total hypericin. Six hours after the single high dose, mean levels of total hypericin were 43 ng/mL in serum and 5.3 ng/mL in skin blister fluid. After 3 tablets daily for one week, mean levels were 12.5 ng/mL in serum and 2.8 ng/mL in skin blister fluid [Schempp 1999].

Plasma levels of hyperforin were measured over a 24-hour period in volunteers treated with 300 mg of an ethanolic extract containing 14.8 mg of hyperforin. Maximum plasma levels of about 150 ng/mL were reached 3.5 hours after oral administration. Half-life and mean residence time of hyperforin were 9 and 12 hours respectively. Up to 600 mg of the extract, hyperforin kinetics were linear [Biber 1998].

In a phase I dose escalation study, patients received oral doses of hypericin once daily for 8 weeks, at either 0.05 mg/kg (n=12) or 0.1 mg/kg (n=7). At the end of the 8 week period, pharmacokinetic data revealed a long elimination half-life (mean values of 36.1 and 33.8 h respectively) and mean AUC determinations of 1.5 and 3.1 mg×h/mL respectively [Jacobson 2001].

In a placebo-controlled, randomised, double-blind study, 33 healthy volunteers received a methanolic (80%) extract alongside various co-medications (placebo, cimetidine and carbamazepine) for 7 days, after a run-in period of 11 days with extract alone. No significant differences in AUC(0-24), C_{max}, and t_{max} values for hypericin and pseudohypericin were observed between the treatment groups [Johne 2004].

The bioavailability of five constituents from an ethanolic (80%) extract was determined in two open clinical trials in 18 healthy male volunteers. Subjects received the extract (612 mg/day p.o.) either as a single oral dose or as a daily dose over a period of 14 days. Concentration/time curves were determined for hypericin, pseudohypericin, hyperforin, quercetin and isorhamnetin for 48 h after single dosing and for 24 h on day 14 at the end of 2 weeks of continuous daily dosing. After single dose administration, the key pharmacokinetic parameters were determined as follows: hypericin: AUC(0-infinity) = 75.96 ng×h/mL, C_{max} = 3.14 ng/mL,

t_{max} = 8.1 h, $t_{1/2}$ = 23.76 h; pseudohypericin: AUC(0-infinity) = 93.03 ng$_x$h/mL, C_{max} = 8.50 ng/mL, t_{max} = 3.0 h, $t_{1/2}$ = 25.39 h; hyperforin: AUC(0-max) = 1009.0 ng$_x$h/mL, C_{max} = 83.5 ng/mL, t_{max} = 4.4 h, $t_{1/2}$ = 19.64 h. Quercetin and isorhamnetin showed two peaks of maximum plasma concentration separated by about 4 h. Quercetin: AUC(0-infinity) = 318.7 ng$_x$h/mL, C_{max}, 1 = 47.7 ng/mL, t_{max}, 1 = 1.17 h, C_{max}, 2 = 43.8 ng/mL, t_{max}, 2 = 5.47 h, $t_{1/2}$ = 4.16 h; isorhamnetin: AUC(0-infinity) = 98.0 ng$_x$h/mL, C_{max}, 1 = 7.6 ng/mL, t_{max}, 1 = 1.53 h, C_{max}, 2 = 9.0 ng/mL, t_{max}, 2 = 6.42 h, $t_{1/2}$ = 4.45 h. Similar results were obtained under the steady-state conditions reached during multiple dose administration [Schulz 2005].

Interactions

The acute effects of an unspecified extract on CYP2D6 and CYP3A4 activity were studied in 7 healthy volunteers given a dose of 3×300 mg/day p.o. for 3 days. Enzyme activity was assessed by phenotyping, using as probes 30 mg dextromethorphan (DM) for CYP2D6 and alprazolam (ALPZ) for CYP3A4. Each probe was given before and during co-administration with the extract. Pharmacokinetics of ALPZ were measured in plasma, while DM and its metabolite dextrorphan (DX) were measured in urine after collection for 8 hours, and the metabolic ratio DM-DX was determined. Compared to baseline, no significant differences were observed for ALPZ or DM-DX ratios when probes were given during treatment with the extract [Markowitz 2000].

The effects of a methanolic extract (80%, V/V; 3 × 300 mg/day for 14 days) on the activity of CYP3A4 and CYP2D6 were assessed in 13 healthy volunteers by determination of the urinary 6-β-hydrocortisol/cortisol and dextromethorphan–dextrorphan (DM/DX) ratios at baseline and at the end of treatment [Roby 2001]. The CYP2D6 participants received an additional 30 mg of dextromethorphan hydrobromide on day 15. On the last day of both studies urine was collected over 24 hours and concentrations of 6-β-hydroxycortisol and cortisol and urinary DM–DX ratios were determined. The mean urinary 6-β-hydroxycortisol/cortisol ratio significantly increased (p=0.003) from a baseline value of 7.1 ± 4.5 to 13 ± 4.9. No significant change was seen for DM-DX ratios [Roby 2000].

The effects of a methanolic (80%) extract on the urinary excretion of D-glucaric acid, 6β-hydroxycortisol and free cortisol were investigated in order to assess its impact on the activity of hepatic xenobiotic metabolising enzymes. Forty-eight healthy volunteers (25 males and 23 females) received a daily dose of 1800 mg of extract for 14 days. Urinary excretion of D glucaric acid was unaffected after the 14-day treatment, whereas excretion of 6β-hydroxycortisol significantly increased from a mean baseline value of 254 µg/day to 369 µg/day (p<0.0001). The excretion of free cortisol was unaltered, but the ratio of 6β-hydroxycortisol to free cortisol changed significantly (p<0.001) from 9.9 at baseline to 14.3. Thus, high-dose treatment with the extract induced CYP3A activity in healthy volunteers as evidenced by increased 6β-hydroxycortisol excretion [Bauer 2002].

In a patient under long-term treatment with CyA (125 – 150 mg/day) and prednisolone (5 mg/day), stable blood levels of CyA between 100 and 130 pg/L suddenly decreased to around 70 pg/L, despite the daily dose being raised to 250 mg. The patient had started to drink a herbal tea containing St. John's wort to control seasonal depressive symptoms. Five days after cessation of the tea, CyA blood levels increased from 70 to 170 µg/L (250 mg/day), and a subsequent dose reduction to 175 mg/day resulted in blood levels of around 130 pg/L [Alscher 2003].

Treatment of four patients on methadone medication with an unspecified extract (900 mg/d) for between 14 and 47 days resulted in a major reduction of (R,S)-methadone concentration-to-dose ratios, with a median decrease to 47% of the original concentration (range: 19% - 60% of the original concentration). Two patients reported symptoms that suggested a withdrawal syndrome [Eich-Hochli 2003].

Twelve healthy men, 6 extensive metabolisers of CYP2C19 (2C19*1 / 2C19*1) and 6 poor metabolisers (4 with 2C19*2 / 2C19*2 and 2 with 2C19*2 / 2C19*3), were enrolled in a two-phase, randomised, crossover study. All subjects took oral doses of either an unspecified extract (0.3% hypericin and a minimum 4% hyperforin; 300 mg) or placebo three times daily for 14 days, and the activities of CYP2C19 and CYP1A2 were measured using mephenytoin and caffeine. The extract significantly increased CYP2C19 activity in CYP2C19 wild-genotype subjects, with urinary 4'-hydroxymephenytoin excretion raised by 151.5% ± 91.9% (p=0.0156), whereas no significant alteration was observed for CYP2C19 poor metabolisers. Repeated extract administration did not affect the CYP1A2 phenotypic ratio for either CYP2C19 genotype subjects [Wang 2004b].

In a trial involving 340 outpatients with major depression, treated with either a methanolic extract (80%; 900-1500 mg/day), SERT (50-100 mg/day) or placebo for 8 weeks, treatment adherence was assessed by measuring plasma hyperforin. Samples from the placebo and extract groups were assayed for hyperforin, and samples from the SERT group for SERT/N-desmethyl-SERT. Of the 104 patients randomised to placebo, 18 (17%) had detectable plasma hyperforin. Of the 97 patients randomised to the extract, 17 (17%) had no detectable plasma hyperforin. All the assayed SERT patients (n = 91) had detectable plasma SERT/N-desmethyl-SERT plasma concentrations. The clinical trial conclusions remained unchanged when only patients with plasma assay consistent with random assignment were included in the analyses [Vitiello 2005].

Healthy volunteers (n = 18) received a methanolic (80%, V/V) extract at a dose of 3 × 300 mg daily for 14 days. The CYP2D6 substrate debrisoquine (5 mg) was administered before and at the end of treatment. CYP2D6 activity was assessed using 8-hour debrisoquine urinary recovery ratios (DURR): [4-hydroxydebrisoquine/(debrisoquine + 4-hydroxydebrisoquine)]. No significant effect on CYP2D6 activity was found [Gurley 2008a].

The effects of an unspecified extract (3 x 300 mg/day p.o.) on oral contraceptive (OC) therapy (1 mg norethindrone and 20 µg ethinyl oestradiol), ovarian activity and break-through bleeding were studied in sixteen healthy women treated for two consecutive 28-day cycles in a single-blind sequential trial. Treatment with the extract resulted in a significant 13-15% (p=0.021) reduction in the dose exposure to the contraceptive. Breakthrough bleeding increased in the treatment cycles, as did evidence of follicle growth and probable ovulation [Murphy 2005].

To investigate whether administration of a methanolic (80%) extract at an oral dose of 3×300 mg together with an OC (20 µg ethinyl oestradiol and 1 mg norethindrone acetate) modified elevated serum androgen levels in OC treatment of hirsutism and acne, 15 healthy women received OC alone for 2 menstrual cycles, followed by two cycles with addition of the extract. No significant differences in testosterone, free testosterone, androstendione, dehydroepiandrosterone, 3α-diol-glucuronide, dehydrotestosterone and or sex hormone binding globulin were observed during the co-administration [Fogle 2006].

The time for recovery to baseline activity of CYP3A after induction by an unspecified extract was studied in 12 healthy males. The volunteers received an oral dose of 5 mg midazolam and from

the next day 3 × 300 mg/day of the extract p.o. for 14 days. On the last day of treatment, and 3 and 7 days later, they received the same dose of midazolam. Compared to baseline, oral clearance of midazolam was significantly (p=0.001) increased after the extract, from 65.3 ± 8.4 L/h to 86.8 ± 17.3 L/h. It returned to the control level 7 days after the last dose of extract (day 7; 59.7 ± 3.8 L/h) [Imai 2008].

Five cancer patients received irinotecan (IT) at a dose of 350 mg/m^2 i.v. once every 3 weeks. An unspecified extract was given at a daily dose of 3 x 300 mg for 14 days, from before the first IT administration until 4 days after IT administration. Myelosuppression was clearly more pronounced with IT alone (decrease in leukocyte and neutrophil counts of 56% and 63% respectively) than after co-administration with the extract (8.6% and 4.3% respectively). The AUC of the active metabolite decreased by 42% (p=0.033) [Mathijssen 2002].

In a study involving 16 healthy volunteers, the effects of a methanolic extract (80%, V/V; 3 × 300 mg/day p.o. for 14 days) on the activities of CYP1A2, CYP2D6, CYP3A4, *N*-acetyltransferase 2 (NAT2) and xanthine oxidase (XO) were assessed by phenotyping before and at the end of treatment. Probes for enzyme activities were ratios of metabolites 17MX/137MX from caffeine (CYP1A2), DM/DX (CYP2D6), endogenous 6-hydroxycortisol/cortisol (CYP3A4), AFMU/1MX from caffeine (NAT2) and 1MU/1MX from caffeine (XO), found in saliva or urine. From these metabolic ratios an induction of CYP3A4 by the extract was confirmed. CYP1A2 was induced only in females. The activities of CYP2D6, NAT2 and XO were not affected [Wenk 2004].

In a controlled, open-label study, acute and long-term effects of a methanolic extract (80%, V/V; 3 × 300 mg/day p.o. for 15 days) on the pharmacokinetics of voriconazole (VCZ) were investigated in 16 healthy male subjects. Since the extensive metabolism of VCZ is primarily mediated by CYP2C19 and CYP3A4, and to a minor extent by CYP2C9, subjects were genotyped for the CYP2C19 alleles *2 and *3. A single dose of VCZ (400 mg) was given on days -3 (baseline), 1 and 15. On days 1 and 15, the extract was administered 60 min before VCZ adminis¬tration. On day 1 of extract administration the AUC(0-10h) of VCZ was increased by 22% compared with control (15.5 ± 6.84 h×µg/mL versus 12.7 ± 4.16 h×µg/mL; p=0.02). After 15 days intake, the AUC(0-10h) was reduced by 59% compared with control (9.63 ± 6.03 h×µg/mL versus 23.5 ± 15.6 h×µg/mL; p=0.0004), with a corresponding increase in oral VCZ clearance (CL/F) from 390 ± 192 to 952 ± 524 mL/min (p=0.0004). The baseline CL/F of VCZ and the absolute increase in CL/F were smaller in carriers of 1 or 2 deficient CYP2C19*2 alleles compared with wild-type individuals (p<0.03) [Rengelshausen 2005].

The net effect of simultaneous administration of an inducer of CYP3A4 (St. John's wort) and an inhibitor (ritonavir) was investigated in 12 healthy volunteers in an open, fixed sequence study design. The CYP3A4 probe midazolam (MDZ) was given orally (4 mg) as a single dose in 4 different study phases: (i) at baseline, (ii) after a single oral dose of either a methanolic extract (80%, V/V; 300 mg) or ritonavir (3 × 100 mg) (n = 6 each), (iii) after 14 days of co-administration of ritonavir (2 × 300 mg daily) and the extract (3 × 300 mg daily), and (iv) at 2 days after cessation of both the extract and ritonavir. Each oral MDZ administration was followed by an intravenous MDZ injection of 2 mg 6 h later ('*semi-simultaneous administration*'). Combined administration of inducer and inhibitor resulted in a predominance of enzyme inhibition: co-administration of the extract and ritonavir with i.v. administration of MDZ showed an increase in the MDZ AUC(0–8h) to 180% of baseline value (p<0.05), whereas with orally administered MDZ, the AUC0–6h increased to 412% of baseline value (p<0.05). After cessation of the co-administered drugs, the AUC(0–6h) of orally administered MDZ decreased to 6% of the level observed during combined administration, and the AUC(0–8h) of i.v. administered midazolam decreased to 33% of the values observed during combined administration (p<0.001 for each) [Hafner 2010].

A male patient with ADHD who had been successfully treated with methylphenidate (20 mg/day), as measured by a reduction in Conner's score (CS) from 75.3 to 68.4, began additional self-medication with an unspecified extract (600 mg/day) six months after starting on the methylphenidate. Treatment with the extract for 4 months diminished the efficacy of methylphenidate, demonstrated by an increase in the CS from 68.4 to 74.9. Three weeks after discontinuation of the extract, the CS dropped back down again to 70.3 [Niederhofer 2007].

The interaction of atorvastatin (10 – 40 mg daily) and an unspecified extract (300 mg twice daily) was studied in a controlled, randomised, open, crossover study involving 16 patients with hypercholesterolaemia. After a 4-week run-in period, patients on a stable atorvastatin dose were randomised to additional treatment with either the extract or control for 4 weeks. The extract significantly increased the serum level of LDL cholesterol compared with control (2.66 mmol/L vs. 2.34 mmol/L; p=0.004) and of total cholesterol (5.10 mmol/L vs. 4.78 mmol/L; p=0.02). No significant changes were observed in HDL cholesterol or in triglycerides [Andren 2007].

The interaction of simvastatin (10 – 40 mg daily) and an unspecified extract (300 mg twice daily) was investigated in a similar study involving 24 patients with hypercholesterolaemia. After a 4-week run-in period, patients on a stable simvastatin dose received either the extract or control for 4 weeks. Compared to control, total cholesterol, LDL-cholesterol and triglycerides increased significantly in the extract group after 4 weeks: 4.56 vs. 5.08 mmol/L (p<0.001), 2.30 vs. 2.72 mmol/L (p<0.0001) and 1.30 vs. 1.54 mmol/L (p=0.0155) respectively. No significant differences were observed for HDL-cholesterol [Eggertsen 2007].

Table 2 below summarises the interactions of St. John's wort extracts with other drugs from clinical studies:

Preclinical safety data
Systematic studies on single dose toxicity, reproductive toxicity and carcinogenicity of St. John's wort extracts have been carried out by major manufacturers, but not published.

Acute toxicity
No data available

Repeated dose and chronic toxicity studies
No significant tissue lesions or adverse events were observed in male Long-Evans rats fed St. John's wort (SJW; locally collected in the fully blooming stage) at 5% of their diet for 119 days. Feeding SJW in conjunction with *Senecio jacobaea* did not influence the chronic toxicity of *Senecio* as assessed by rat survival time. SJW did not affect hepatic copper levels [Garrett 1982].

No signs of toxicity were observed following administration of dried herb to rats at up to 2 g/kg/day for one year, at 3 g/kg/day for 28 days, and to dogs at 2 g/kg/day for 1 year. Tolerability levels of < 10 g/kg wet weight, eaten at the flowering stage, and < 2.65 mg/kg for hypericin were demonstrated in sheep. Non-specific toxic symptoms, including slight load damage to liver and kidneys, were observed after administration of 0.9 and 2.7 g/kg of a methanolic extract (80%, V/V) for 26 weeks in pivotal toxicological models in rats and dogs respectively [Morgan 2005].

TABLE 2: CHANGES IN THE PHARMACOKINETICS OF THE FOLLOWING DRUGS BY CO-ADMINISTRATION OF ST. JOHN'S WORT

Drug	Subjects	Type of preparation, posology (mg/day) and duration of administration	Effect on blood levels (AUC)	Presumed Mechanism	References
Alprazolam	Healthy subjects	900 mg of a methanolic (80%) extract for 12-14 days	53.6% decrease	CYP3A4	[Markowitz 2003]
Amitriptyline	Healthy subjects (n = 12)	900 mg of a methanolic (80%) extract for 12-14 days	22% decrease	CYP3A4	[Johne 2002]
Boceprevir	Healthy subjects (n = 17)	600 mg of an ethanolic (60%) extract for 14 days	No significant effect		[Jackson 2014]
Bupropion	Healthy subjects (n = 18)	975 mg of an unspecified extract for 14 days	14.3% decrease	CYP2B6	[Lei 2010]
Caffeine	Healthy subjects (n = 12)	900 mg of a methanolic (80%) extract for 2 weeks	No significant effect		[Wang 2001]
Carbamazepine	Healthy subjects (n = 8)	900 mg of a methanolic (80%) extract for 14 days	No significant effect		[Burstein 2000]
Ciclosporin	Transplant patients (n=7)	900 mg of a methanolic (80%) extract for 14 days	Increased clearance	CYP3A4, Pgp	[Ruschitzka 2000] [Mai 2000] [Karliova 2000] [Mandelbaum 2000] [Barone 2001]
Ciclosporin	1 patient	Unspecified extract	Significant decrease	CYP3A4, Pgp	[Barone 2000]
Ciclosporin	Kidney transplants (n = 11)	600 mg of a methanolic extract	42% decrease	CYP3A4, Pgp	[Bauer 2003]
Ciclosporin	Kidney transplant (n = 30)	Unknown	47% decrease	CYP3A4, Pgp	[Breidenbach 2000]
Ciclosporin	Healthy subjects (n = 21)	900 mg of a methanolic (80%) extract for 10 days	38.6% decrease	CYP, Pgp	[Dresser 2003]
Ciclosporin	Transplant patients (n = 10)	900 mg of a methanolic (80%) extract	51.9% decrease	CYP, Pgp	[Mai 2004]
Clozapine	1 Patient	900 mg unspecified extract for 3 weeks	65.2% decrease in trough levels	CYP1A2 CYP3A4	[Van Strater 2011]
Dextromethorphan	Healthy subjects (n = 12)	900 mg of methanolic (80%) extract	No significant effect	CYP2D6	[Wang 2001]
Desogestrel	Healthy women (n = 18)	600 and 900 mg of a methanolic (80%) extract for 4 weeks	43.9% decrease	CYP3A4	[Pfrunder 2003]
Digoxin	Healthy subjects (n = 13)	900 mg of a methanolic (80%) extract for 10 days	25% decrease	Pgp	[Johne 1999]
Digoxin	Healthy subjects (n = 96)	Different extracts for 10 days	mg/day hyperforin / % decrease 28.9 / 24.8 21.1/ 26.6 10.6/ 17.7 5.3 /1.8 3.56/ 7.3 2.6/ -1.5 0.83/ -5.6 0.13/ 5.2 0.3/ 9 0.04/0.3 Placebo/6.4	Pgp	[Mueller 2004]
Digoxin	Healthy subjects (n = 18)	900 mg of a methanolic (80%) extract for 14 days	23% decrease	Pgp	[Gurley 2008b]
Digoxin	Healthy subjects (n = 8)	900 mg of a methanolic extract (80%) for 14 days	18% decrease	Pgp	[Dürr 2000]
Ethinyloestradiol	Healthy women (n = 12)	900 mg of an unspecified extract (3% hyperforin) for 28 days	No significant effect		[Hall 2003]
Ethinyloestradiol	Healthy women (n = 18)	600 and 900 mg of a methanolic (80%) extract for 4 weeks	No significant effect		[Pfrunder 2003]

Drug	Subjects	Type of preparation, posology (mg/day) and duration of administration	Effect on blood levels (AUC)	Presumed Mechanism	References
Ethinyloestradiol	Healthy women (n = 16)	900 mg of an unspecified extract for two times 28 days	14.1% decrease	CYP, Pgp	[Murphy 2005]
Fexofenadine	Healthy subjects (n = 12)	900 mg of a methanolic (80%) extract for 14 days	14% decrease, not significant	Pgp	[Wang 2002]
Fexofenadine	Healthy subjects (n = 21)	900 mg of a methanolic (80%) extract for 10 days	48.5% decrease	Pgp	[Dresser 2003]
Finasteride	Healthy volunteers (n = 12)	600 mg of a methanolic (80%) extract for 2 weeks	58% decrease	CYP3A4	[Lundahl 2009]
Gliclazide	Healthy volunteers (n = 21)	900 mg/of a methanolic (80%) extract for 2 weeks	33% decrease	CYP2C9	[Xu 2008]
Ibuprofen	Healthy volunteers (n = 21)	900 mg of an methanolic (80%) extract	No significant decrease		[Bell 2007b]
Imatinib	Healthy volunteers (n = 12)	900 mg of a methanolic (80%) extract for 2 weeks	30% decrease	CYP3A4, Pgp, BCRP	[Frye 2004]
Imatinib	Healthy volunteers (n = 10)	900 mg of an unspecified extract for 2 weeks	32% decrease	CYP3A4, Pgp,	[Smith 2004a; Smith 2004b]
Indinavir	Healthy volunteers (n = 8)	900 mg of a methanolic extract for 2 weeks	57% decrease	CYP3A4, Pgp	[Piscitelli 2000]
Irinotecan	Cancer patients (n = 5)	900 mg of an unspecified extract for 18 days	42% decrease of SN-38	CYP3A4	[Mathijssen 2002]
Ivabradine	Healthy subjects (n = 12)	900 mg of a methanolic (80%) extract for 14 days	61.7% decrease	CYP3A4, Pgp	[Portoles 2006]
Methadone	2 Patients	900 mg of a methanolic extract (> 3% hyperforin) for 31 days	47% decrease	CYP3A4	[Eich-Hochli 2003]
Midazolam	Healthy subjects (n = 12)	900 mg of a methanolic (80%) extract for 2 weeks	52.3% decrease	CYP3A4	[Wang 2001]
Midazolam	Healthy subjects (n = 12)	900 mg of an unspecified extract for 28 days	Significant decrease	CYP3A4, Pgp	[Gurley 2002]
Midazolam	Healthy subjects (n = 21)	900 mg of a methanolic (80%) extract for 10 days	30.6% decrease	CYP3A4	[Dresser 2003]
Midazolam	Healthy women (n = 12)	900 mg of an unspecified extract (3% hyperforin) for 28 days	35% decrease	CYP3A4	[Hall 2003]
Midazolam	Healthy subjects (n = 42)	Different extracts for 14 days	mg/day hyperforin / % decrease 41.25 / 80.0 12.06 / 48.0 8.04 / 36.0 5.36 / 32 2.68 / 22 0.13 / 21	CYP3A4	[Mueller 2006]
Mycophenolate	Transplant patients (n = 10)	600 mg of a methanolic (80%) extract for 14 days	No significant effect		[Mai 2003]
Nevirapine	HIV patients (n = 5)	unknown	decrease	CYPs, Pgp	[De Maat 2001]
Nifedipine	Healthy subjects (n = 12)	900 mg of a methanolic extract for 14 days	45.2% decrease	CYP3A4, Pgp	[Wang 2007]
Norethindrone	Healthy women (n = 12)	900 mg of unspecified extract (3% hyperforin) for 28 days	About 14% decrease	CYP3A4	[Hall 2003]
Norethindrone	Healthy women (n = 16)	900 mg of unspecified extract for two times 28 days	12.6% decrease	CYP, Pgp	[Murphy 2005]
Omeprazole	Healthy subjects (n = 12)	900 mg of a methanolic (4% hyperforin) extract for 14 days	37.9% decrease	CYP3A4, CYP2C19	[Wang 2004c]
Oxycodon	Healthy subjects (n = 12)	900 mg of a methanolic (80%) extract for 15 days	50% decrease	CYP3A4	[Nieminen 2010]
Phenprocoumon	Healthy subjects (n = 10)	900 mg of a methanolic (4% hyperforin) extract for 14 days	17.4% decrease	CYP3A4	[Maurer 1999]

Drug	Subjects	Type of preparation, posology (mg/day) and duration of administration	Effect on blood levels (AUC)	Presumed Mechanism	References
Phenytoin	Healthy subjects (n = 12)	900 mg methanolic (4% hyperforin) extract for 14 days	Increased metabolism	CYP2C19	[Wang 2004b]
Pravastatin	Healthy subjects (n = 16)	900 mg of unspecified extract for 14 days	No significant effect		[Sugimoto 2001]
Prednison Prednisolone	Healthy subjects (n = 8)	900 mg of a methanolic extract (> 3% hyperforin) for 4 weeks	No significant effect		[Bell 2007a]
Quazepam	Healthy subjects (n = 13)	900 mg of an unspecified extract for 14 days	28.5% decrease	CYP2C9	[Kawaguchi 2004]
Repaglinide	Healthy subjects (n = 15)	975 mg of an unspecified extract for 14 days	No significant effect		[Fan 2011]
Simvastatin	Healthy subjects (n = 16)	900 mg of unspecified extract for 14 days	48% decrease	CYP3A4, Pgp	[Sugimoto 2001]
Tacrolimus	Transplant patients (n = 10)	600 mg of a methanolic (80%) extract for 14 days	57.8% decrease	CYP3A4, Pgp	[Mai 2003]
Tacrolimus	Healthy subjects (n = 10)	900 mg of a methanolic (80%) extract for 18 days	35.3% decrease	CYP3A4, Pgp	[Hebert 2004]
Talinolol	Healthy subjects (n = 9)	900 mg of a methanolic (80%) extract for 12 days	31% decrease	Pgp	[Schwarz 2007]
Theophylline	Healthy subjects (n = 12)	900 mg of an unspecified extract for 15 days	No significant effect		[Morimoto 2004]
Verapamil	Healthy subjects (n = 8)	900 mg of an unspecified extract for 14 days	78% (R-verapamil) and 80% (S-verapamil) decrease	CYP3A4, Pgp	[Tannergren 2004]
Voriconazole	Healthy subjects (n = 16)	900 mg of a methanolic (80%) extract for 15 days	59% decrease	CYP3A4, CYP2C9, CYP2C19	[Rengelshausen 2005]
Warfarin	Healthy subjects (n = 12)	3000 mg of an unspecified extract for 14 days	27% and 24.6% decrease for S- and R-warfarin	CYP3A4, CYP2C9, CYP1A2	[Jiang 2004]
Zolpidem	Healthy subjects (n = 14)	900 mg of a methanolic (80%) extract for 14 days	30.3% decrease	CYP3A4, CYP2C9 CYP1A2	[Hojo 2011]
Low-dose hyperforin					
Alprazolam	Healthy subjects (n = 28)	240 mg of a low hyperforin extract for 10 days	No significant effect		[Arold 2005]
Caffeine	Healthy subjects (n = 28)	240 mg of a low hyperforin extract for 10 days	No significant effect		[Arold 2005]
Ciclosporin	Transplant Patients (n = 10)	900 mg of an unspecified low hyperforin extract	No significant effect	CYP, Pgp	[Mai 2004]
Desogestrel	Healthy women (n = 16)	500 mg of a low hyperforin ethanolic extract (57.9%) for 14 days	No significant effect		[Will-Shahab 2008]
Digoxin	Healthy subjects (n = 28)	240 mg of a low hyperforin extract for 10 days	No significant effect		[Arold 2005]
Ethinylestradiol	Healthy women (n = 16)	500 mg of a low hyperforin ethanolic extract (57.9%) for 14 days	No significant effect		[Will-Shahab 2008]
Midazolam	Healthy subjects (n = 42)	900 mg of an unspecified low hyperforin extract for 14 days (Hyperforin 0.13 mg/day)	No significant effect		[Mueller 2006]
Midazolam	Healthy subjects (n = 20)	1000 mg of an unspecified low hyperforin extract or 14 days	No significant effect		[Mueller 2009]
Tolbutamide	Healthy subjects (n = 28)	240 mg of a low hyperforin extract for 10 days	No significant effect		[Arold 2005]

Mutagenicity and carcinogenicity

Genotoxicity
No increase in the extent of DNA fragmentation was observed on addition of a methanolic (80%, V/V) extract to rat cortical cells. The cells were incubated for 18 hours with concentrations up to 40 µg/mL [Perovic 1995].

Genotoxicity of a standardised aqueous ethanolic extract was investigated in various *in vivo* and *in vitro* test systems. No suggestion of mutagenicity was found. The testing involved: A) Hypoxanthine guanidine phosphoribosyl transferase-test in Chinese hamster V79 cells with extract concentrations up to 0.50 µg/mL (without S9-mix) or 4 µg/mL (with S9-mix); B) Unscheduled DNA synthesis assay in primary rat hepatocytes with extract concentrations up to 1.37 µg/Ml; C) Cell transformation test using S9-mix activated Syrian hamster embryo cells, the extract was added in concentrations up to 10 µg/Ml; D) Fur spot test in NMRI mice with oral doses of up to 10 mL/kg of test substance; and E) Chromosome aberration test with bone marrow cells of Chinese hamsters receiving oral doses of up to 10 mL/kg of the extract [Okpanyi 1990].

Carcinogenicity
No data are available

Reproductive toxicity

In vitro experiments
Hamster oocytes were incubated with an extract before sperm/oocyte interaction. Penetration was prevented by a very high dose of 0.6 mg/mL, but 0.06 mg/mL had no effect [Vandenbogaerde 1998].

In an explanted Sprague-Dawley rat embryo model, enabling the study of embryonic development during the critical period of organogenesis from 9.5 to 11.5 gestational days, exposures to high concentrations of hypericin (71.0 and 142.0 ng/mL) demonstrated a significantly lower total morphological score ($p=0.002$) and number of somites ($p<0.001$) compared to control. A significant negative linear trend in total morphological score ($p<0.001$), yolk sac diameter ($p=0.01$), and number of somites ($p<0.01$) was observed with increasing concentration of hypericin. No statistical difference was detected in crown-rump length [Chan 2001].

In vivo experiments
Exposure of Sprague-Dawley rats to diets containing 0, 180, 900, 1800 or 4500 ppm of an unspecified extract beginning on gestational day 3 and ending at off-spring weaning on postnatal day (PND) 21 did not reveal any effects on maternal weight gain, duration of gestation or extract-related behavioural alterations. Brain weights of offspring at adulthood indicated no significant effects of the extract [Cada 2001].

A methanolic (80%) extract was administered to female rats during the period of organogenesis (gestational days 9-15). Thirty inseminated Wistar rats received oral doses of saline or 36 mg/kg of the extract. No clinical signs of maternal toxicity were observed and none of the variables analysed in foetuses and placentas showed significant differences [Borges 2005].

The effect of treatment with high doses of an unspecified methanolic extract (100 and 1000 mg/kg/day), administered prenatally and during breastfeeding, on the level of transcripts of mdrla, mdr1b, mrp1, mrp2 and cyp3A2 genes was studied in Wistar rats. All transcripts were detected in the liver, and their level of expression increased from foetuses to adults. Extract administration, at both dosages, caused a significant ($p<0.01$) decrease of the levels of mdr1a, mdr1b, mrp1 and mrp2 in the livers of foetuses, and an increase ($p<0.01$) in the levels of mdrla, mdrlb, mrp2 and cyp3A2 in the mothers [Garrovo 2006].

High concentrations of hyperforin (> 1 µM) inhibited mouse embryonic stem (ES) cell population growth ($p<0.05$) and induced apoptosis ($p<0.05$) in fibroblasts (representing adult tissues). Hyperforin affected ES cell differentiation into cardiomyocytes in a dose-dependent manner ($p<0.05$). Analysis of tissue-specific marker expression also revealed that hyperforin at high concentrations partially inhibited ES cell differentiation into mesodermal and endodermal lineages [Nakamura 2013].

Effects on offspring
Treatment of male CD rats for 14 days with 500 mg/kg daily of a methanolic (80%, V/V) extract, hypericin 0.1 mg/kg, or hypericin combined with procyanidin B_2 1:25, did not lead to any changes in the reproductive organs [Butterweck 2001a].

The cognitive impact of prenatal exposure to an extract (0.3% hypericin, solvent not specified, 182 mg/kg/day) was studied in CD1 mice. The extract or a placebo was consumed in food bars for 2 weeks before mating and throughout gestation. One offspring per gender from each litter (verum 13, placebo 12) was tested using the juvenile runway with adult memory, adult Morris spatial water maze, adult passive avoidance and adult straight water runway, followed by a dry Cincinnati maze. Learning occurred in both genders in all tasks ($p<0.003$) with no significant differences between treatments at the final trial. Female offspring exposed to the extract, rather than to placebo, required more time to learn the MWM task ($p<0.05$). Post-learning sessions did not show any significant differences [Rayburn 2001a].

Female mice were treated orally with 180 mg/kg/day of the same extract or placebo for 2 weeks before conception and throughout gestation. Gestational age at delivery and litter size did not differ between the groups. Body weight, body length and head circumference from postnatal day 3 to adulthood did not differ from controls regardless of gender. The only difference between the groups was a temporary delay in the eruption of upper incisors in male offspring exposed to the extract. The extract did not affect reproductive capacity, perinatal outcomes, or growth and development of second-generation offspring [Rayburn 2001b].

A methanolic extract (0.3% total hypericin) given to Wistar rats at doses of 100 and 1000 mg/kg/day by gavage during pregnancy and lactation revealed severe damage in the livers and kidneys of new-born animals euthanised post-natally on days 0 and 21 at both doses. The lesions were more severe at the higher dose and in animals that were breastfed for 21 days [Gregoretti 2004].

A methanolic extract (80%, V/V) at a dose of 36 mg/kg was given to 30 pregnant Wistar rats during organogenesis (days 9 - 15 of pregnancy). No clinical signs of maternal toxicity were observed in the necropsy on day 21. The indices of implantation and resorption, and toxicological parameters (such as foetus and placenta weight), were not significantly different compared to control [Borges 2005].

In a systematic review on the safety of St. John's wort during pregnancy and lactation, no impact on maternal weight gain or duration of gestation were observed in Sprague-Dawley rats who were exposed to oral doses of St. John's wort 1 to 25 times the recommended human dose. Offspring body weights were similar to controls, although there was a tendency towards lower weight after treatment with St. John's wort. No alterations in behaviour were found [Dugoua 2006].

Organ mRNA expression and protein content of Abcb1 were determined following oral administration of an 80% methanolic extract (hypericin 0.3%) to pregnant female Wistar rats at 1 g/kg for 9 days during late pregnancy. Abcb1 expression was substantially lower in foetal than in maternal organs and significantly induced in the maternal jejunum and placenta [Saljé 2012].

An extract (0.3% hypericin; not further specified) was administered orally to pregnant Wistar rats at 36, 72 or 144 mg/kg per day.The highest dose demonstrated greater head-dipping activity in the hole-board test ($p<0.001$) and reduced immobility in the tail suspension test ($p<0.001$) and FST ($p<0.001$), at 10 and 60 days post-treatment [Vieira 2013b].

Maternal exposure to FLU (7.5 mg/kg) or an unspecified extract (100 mg/kg), given daily by gavage during pregnancy and lactation, showed that FL, but not the extract interfered with reproductive parameters in adult male rats [Vieira 2013a].

Hepatotoxicity

Hypericin and pseudohypericin at a dose of 50 µg (oral, i.v., i.p.) exhibited low toxicity in BALB/c mice and prevented viral-induced manifestations following retrovirus infection. Neither hypericin nor pseudohypericin had an impact on alkaline phosphatase, lactate dehydrogenase, AST, ALT or cholesterol. Haematology and blood biochemistry were unaffected [Meruelo 1988].

Intraperitoneal administration of 280 mg/kg/day of an extract (0.29% total hypericins; 2.29% hyperforin; solvent not specified), 1 mg/kg/d of hypericin or 10 mg/kg/d of hyperforin to male Swiss Webster mice for periods ranging from 4 days to 3 weeks did not induce changes in ALT, and no histological changes in the livers were observed [Bray 2002a; Bray 2002b].

Phototoxicity

Photosensitization caused by St. John's wort has mainly been reported in veterinary studies, especially in unpigmented skin of grazing animals [James 1992]. Dose-dependent phototoxic symptoms were observed in calves within 4 hours after single oral doses of dried St. John's wort at 3 – 5 g/kg [Araya 1981].

Merino ewes (an unpigmented breed, freshly shorn of wool), dosed orally with 5.7, 4.0 or 2.85 g/kg of dried St. John's wort (corresponding to 5.3, 3.7 or 2.65 mg/kg of hypericin) and then exposed to bright sunlight, had a tolerance level for hypericin of less than 2.65 mg/kg [James 1992].

Foetal calf serum or albumin strongly inhibited the photocytotoxic effects of pseudohypericin, but not those of hypericin, in A431 tumour cells [Bernd 1999]. Human keratinocytes were cultured in the presence of various concentrations of an extract and irradiated with UVA or UVB. A phototoxic effect was only seen with high hypericin concentrations (≥ 50 µg/mL) after irradiation with UVA [Rayburn 2001b].

The phototoxic potential of 3 unspecified extracts from various sources, as well as some of their main constituents, was investigated in an immortalised human keratinocyte cell line (HaCaT cells) under UVA irradiation (250 and 700 mJ/cm^2). Known phototoxic compounds like chloropromazine and psoralenes like 5-MOP served as controls. The extracts demonstrated cytotoxicity and photocytotoxicity in a dose- and UVA-dose dependent manner (IC_{50} without irradiation 35 to 74 µg/mL, with irradiation 24 to 84 µg/mL). Hypericin also evoked severe phototoxic effects and was the main phototoxic constituent. Among the tested flavonoids quercitrin and rutin were found to be cytotoxic. However, quercitrin co-administration with the extract diminished the phototoxicity of the latter [Wilhelm 2001].

The phototoxic and apoptosis-inducing capacity of pseudohypericin was compared to hypericin in human leukaemic lymphoma cells (Jurkat). Treatment with both photoactivated hypericin and pseudohypericin resulted in a dose-dependent inhibition of cell proliferation, whereas compounds without photoactivation had no effect at the concentrations tested. The IC_{50} of hypericin was lower (100 ng/mL) than pseudohypericin (200 ng/mL) ($p<0.05$). A dose-dependent increase of DNA fragmentation was observed following treatment with both photoactivated compounds in an apoptosis assay [Schempp 2002b].

Phototoxicity of hypericin to the eye was evaluated in human lens epithelial cells. Cells were exposed to 0.1 – 10 µM hypericin and irradiated with 4 J/cm^2 UVA or 0.9 J/cm^2 visible light. Neither hypericin alone nor light exposure alone reduced cell viability. In contrast, cells exposed to hypericin in combination with UVA or visible light underwent necrosis and apoptosis. The ocular antioxidants lutein and *N*-acetyl cysteine did not prevent damage [He 2004].

The cytotoxicity of various extracts (prepared with ethanol, water, chloroform, hexane) and purified compounds was examined in three cell lines. All extracts exhibited significant cytotoxicity; those prepared in ethanol (no hyperforin, 3.6 µM hypericin, 134.6 µM flavonoids) showed between 7.7 and 77.4% cell survival ($p<0.0001$ and 0.01), whereas the chloroform and hexane extracts (hyperforin, hypericin and flavonoids not detected) showed approximately 9.0% ($p<0.0001$) and 4.0% ($p<0.0001$) survival. Light-sensitive toxicity was observed primarily with the ethanol extracts sequentially extracted following removal of material extracted in either chloroform or hexane. The absence of light-sensitive toxicity with the extracts suggests that the hypericins were not playing a prominent role in the toxicity of the extracts [Schmitt 2006].

The phototoxic effects of 0.1 - 10 µM hypericin were investigated further in combination with visible light on the human retina. Fluorescence emission confirmed hypericin uptake by human retinal pigment epithelial cells (hRPE). When irradiated with 0.7 J/cm^2 of visible light ($\lambda > 400$ nm) loss of cell viability as measured by mitochondrial activity and cell membrane damage was observed. Hypericin in irradiated hRPE cells significantly changed the redox equilibrium of glutathione and decreased the activity of glutathione reductase. Increased lipid peroxidation was correlated to hypericin concentration in hRPE cells and visible light radiation [Wielgus 2007].

Mild phototoxicity was observed after topical administration of hypericin at a dose of 0.01 to 1% [Boiy 2008].

Neither hypericin exposure nor UVA irradiation alone reduced the cell viability of human pigmented and unpigmented melanoma cells, immortalised keratinocytes and melanocytes. An exposure to 1 µM UVA-activated hypericin did not change cell viability, while 3 µM activated hypericin induced necrosis in pigmented melanoma cells and melanocytes and apoptosis in cells without melanosomes (non-pigmented melanoma cells and keratinocytes). Hypericin localisation in the endoplasmic reticulum in these cells, shown by fluorescent microscopy, further supported a disruption in cellular processing and induction of cell death. It was demonstrated that intracellular accumulation of hypericin induced mitochondrial-associated caspase-dependent apoptosis [Davids 2008].

The photobiochemical properties of an extract and 19 known

constituents were characterised with a focus on generation of ROS, lipid peroxidation and DNA photocleavage as indicators of photosensitive, photoirritant and photogenotoxic potentials. The ROS assay revealed the photoreactivity of the extract and some constituents as evidenced by type I and/or II photochemical reactions under light exposure. Only hypericin, pseudohypericin and hyperforin exhibited *in vitro* photoirritant potential [Onoue 2011].

Fluorescence confocal microscopy was used to visualise binding between hypericin and α-crystallin, a major lens protein, in a human lens epithelial (HLE) cell line. UVA irradiation of hypericin-treated HLE cells resulted in a decrease in α-crystallin detection concurrent with an accumulation of the tryptophan oxidation product *N*-formylkynurenine (NFK). Examination of actin in HLE cells indicated that it accumulated NFK resulting from hypericin-mediated photosensitisation. Wavelengths < 400nm provided an incomplete protection against α-crystallin modification and NFK accumulation [Ehrenshaft 2013].

Clinical safety data

At therapeutic dose levels (up to the equivalent of 6 g of drug), occasional mild gastrointestinal disturbances, nausea, restlessness, fatigue, headache, insomnia or allergic reactions have been reported [Albrecht 1994; Bergmann 1993; Bernhardt 1996; De Maat 2001; Engesser 1996; Grube 1999; Halama 1991; Hänsgen 1996; Häring 1996; Harrer 1994; Harrer 1991; Harrer 1999; Hoffmann 1979; Holsboer-Trachsler 1999; Hübner 1994; Kaehler 1999; Kalb 2001; Kasper 2010; Knüppel 2004; Kugler 1990; Laakmann 1998; Lecrubier 2002; Lehrl 1993; Lenoir 1999; Martinez 1994; Meier 1997; Mueller 1998; Pieschl 1989; Quandt 1993; Rahimi 2009; Reh 1992; Röder 2004; Schakau 1996; Schlich 1987; Schmidt 1989; Schrader 2000; Schrader 1998; Schulz 2001; Sepehrmanesh 1999; Sommer 1994; Vorbach 1994; Warnecke 1986; Werth 1989; Wheatley 1997; Witte 1995; Woelk 2000a; Woelk 1994]. Onset of mania and hypomania were reported in several patients with latent bipolar disorders [Barbenel 2000; Fahmi 2002; Moses 2000; Nierenberg 1999; O'Breasail 1998; Saraga 2005; Schneck 1998; Stevinson 2004]. In one patient taking up to 3600 mg of a methanolic extract acute psychotic symptoms were observed that recovered completely after termination of treatment [Shimizu 2004].

A detailed overview of the pharmacological, toxicological and clinical literature on St. John's wort is provided in several reviews [Ernst 1995; Greeson 2001; Nathan 2001; Russo 2014].

In a meta-analysis of 35 double-blind randomised trials and observational studies of St. John's wort mono-preparations, drop-out and adverse event rates were extracted from 17 observational studies including 35,562 patients. Drop-out rates ranged between 0% and 5.9%. No serious adverse effects were reported. In 24 double-blind, randomised trials (n = 1,334 St. John's wort, n = 1,292 placebo) drop-out and adverse effect rates were similar to placebo (OR = 0.82 (CI = 0.64 to 1.06) and 0.79 (CI = 0.51 to 1.03) respectively). In 7 studies *versus* older antidepressants, drop-out and adverse effect rates were significantly lower in the St. John's wort group (OR = 0.25 (CI = 0.14 to 0.45) and 0.39 (CI = 0.31 to 0.50)). In 6 studies *versus* SSRIs, drop-out and adverse effect rates were slightly but not significantly lower in the St. John's wort group (OR = 0.60 (CI = 0.31 to 1.15) and 0.75 (CI = 0.52 to 1.08)) [Knüppel 2004].

The clinical efficacy of some standardised methanolic and ethanolic extracts in the treatment of mild, moderate and severe major depression has been demonstrated in 38 controlled clinical trials and two recent meta-analyses. Sixteen post-marketing surveillance studies with such preparations, based on a total of 34,804 patients, recorded an incidence of adverse events (AEs) among patients between 0% and 6%. Of these studies, the four large-scale surveillance studies with a total of 14,245 patients recorded a rate of AEs ranging from 0.1% to 2.4% and a drop-out rate due to AEs of 0.1-0.9%. AEs associated with St. John's wort treatment were mild and transient in nearly all cases [Schulz 2006b].

In an observational study 1778 patients with depressive symptoms received an extract (3.5-6:1; 425 – 1700 mg) for 12 weeks. The incidence of ADRs was 3.54% and decreased continuously from the first visit onwards; serious ADRs did not occur [Melzer 2010].

Spontaneous ADR reports (n = 84) reported to the Australian Therapeutic Goods Administration (TGA) between 2000 - 2013 were obtained for St. John's wort (SJW). The majority of reported ADRs for SJW were concerning females aged 26-50 years (28.6%). The central nervous system (45.2%) was most affected by ADRs to SJW [Hoban 2015].

Pregnancy and lactation

A prospective, observational, controlled cohort study followed three groups of pregnant women who contacted the Motherisk Program (a teratogen information service in Canada): 54 women using any St. John's wort product at any time during their pregnancy, a disease-match group of 54 women with depression under conventional antidepressant therapy and 54 healthy women not exposed to any known teratogen. Pregnancy outcomes were similar in the three groups. There were 3, 2, and 0 malformations in the St. John's wort, disease-matched and healthy groups respectively. The rate of spontaneous abortion was higher in the St. John's wort (n = 11) and disease-matched control (n = 7) groups compared to the healthy control group (n = 5). Neither finding reached statistical significance. The rate of malformation was as expected in the population [Moretti 2009].

In a cohort study, 33 breastfeeding women presenting to the teratogen/toxicant counselling service taking St. John's wort preparations (not further specified) at an average dose of 704.9 mg/day (range 225 - 2150 mg/day) (group 1) were compared to 101 disease-matched controls (group 2) and 33 age- and parity-matched healthy controls (Group 3). Whereas only 1 infant each in groups 2 and 3 was reported to be colicky, there were 2 cases of "colic", 2 of "drowsiness" and 1 of "lethargy" in group 1. No significant difference was observed in the frequency of maternal reports of decreased milk production among the groups, nor a difference in infant weight over the first year of life [Lee 2003].

In a case report, hypericin and hyperforin were measured in the breast milk of a woman receiving 300 mg of an 80% methanolic extract 3 times a day. Only hyperforin was excreted at minimal levels into breast milk, but not into infant´s plasma [Klier 2002].

An excretion of hyperforin into breast milk was confirmed in 5 other breastfeeding women. Low plasma concentrations of hyperforin were detected in breastfed infant plasma, with a milk-to-plasma ratio of 0.04 to 0.13 corresponding to relative doses of 0.9% to 2.5%. No adverse effects were observed in mothers or infants [Klier 2006].

Phototoxicity and photosensitization

A double-blind, placebo-controlled study with 40 volunteers showed that photosensitivity was not induced by therapeutically relevant dosages of total hypericin, i.e. up to 1 mg daily for 8 days [Wienert 1991].

In a study involving i.v. administration of synthetic hypericin to HIV-infected patients, reversible symptoms of phototoxicity

were observed at the highest dosage regime, which was 35-times higher than the highest oral dosage of total hypericin used in the therapy of depressive disorders [James 1992].

In a placebo-controlled, randomised clinical trial (n = 13), high daily oral doses of up to 3600 mg of a methanolic extract (80%, V/V; corresponding to 11.25 mg hypericin) were administered to volunteers. No dose-related trend in light sensitivity to solar stimulated irradiation (SSI) was observed. Sensitivity to UVA light was slightly but significantly (p=0.03) increased only after the highest dose (from 10.8 J/cm^2 (placebo) to 8.7 J/cm^2 (extract)). After multiple doses of 5.6 mg total hypericin for 15 days, the minimal erythema dose (MED) was assessed. A small but significantly increased SSI sensitivity was observed (decrease in MED from 0.17 to 0.16 J/cm^2, p=0.005) and an increased sensitivity to UVA light (decrease in MED from 9.9 to 7.8 J/cm^2, p<0.0001). In spite of the high doses used, frequency of side effects was equal to placebo medication and light sensitivity was only marginally increased [Brockmöller 1997].

After topical application of St. John's wort oil (110 µg/mL hypericin; n = 8) and St. John's wort ointment (30 µg/mL hypericin; n = 8) to the volar forearms of sixteen volunteers (with skin types II and III), solar simulated radiation was applied. No change of the MED was detected on visual assessment after either treatment (p>0.05). Using photometric measurement of skin erythema, an increase of the erythema-index was observed after treatment with the oil (p≤0.01) [Schempp 2000].

In a prospective randomised study the effect of a methanolic (80%) extract on skin sensitivity to ultraviolet B (UVB), ultraviolet A (UVA), visible light (VIS) and solar simulated radiation was determined. Volunteers of skin types II and III received either a single dose equivalent to 5.4 or 10.8 mg hypericin (n = 48) or an initial dose equivalent to 5.4 mg hypericin, and subsequently 3 x 2.7 mg hypericin per day for 7 days (n = 24). No significant influence on the erythema-index or melanin-index was detected after either dose regimen, with the exception of a marginal influence on UVB induced pigmentation (p=0.0471) in the single-dose study [Schempp 2003b].

Volunteers received 3 x 340 mg of an ethanolic (60%, V/V) extract daily corresponding to 3 mg hypericin over a period of 10 days. Even at this high hypericin concentration, and in spite of the observed decrease in visual and objective MED reduction from 20 to 14 J/cm^2 (p=0.047) and from 33.73 to 22.0 J/cm^2 (p=0.014) respectively, and an increase in erythema intensity (in 73% of subjects), the maximum slope of the dose-response curve (which is an indicator of an individual's susceptibility to burning) was not increased by the extract [Beattie 2005].

The effect of two different ethanolic extracts (50% and 80%) was assessed on photosensitivity with respect to MED after 14 days of treatment. Both open, multiple-dose, phase I studies were conducted in 20 healthy men receiving 612 and 900 mg of the extracts respectively. Mean MED at 24 h, in both studies, was not significantly different between baseline and after 14 days of treatment [Schulz 2006a].

The effect of extract use on cataractogenesis was investigated utilising data from a large, population-based sample. Self-reported data on St. John's wort use in the past 12 months and cataracts were obtained from the 2002 National Health Interview Survey, a nationally representative population-based sample. Crude and adjusted OR and 95% CI between SJW use and cataracts were estimated using logistic regression. After adjusting for potential confounding characteristics, participants that reported having cataracts were 59% more likely to report St. John's wort use (OR 1.59; 95% CI 1.02-2.46) [Booth 2009].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books*, ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009,* but are not available online for copyright reasons.

After purchase of a single monograph*,* the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-kB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-b	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

JUGLANDIS FOLIUM

2024

Walnut leaf

DEFINITION

Walnut leaf consists of the whole or cut dry leaves of *Juglans regia* L. (Juglandaceae). It contains not less than 2.0 per cent of tannins adsorbed by hide powder, expressed as pyrogallol ($C_6H_6O_3$, Mr 126.1) and calculated with reference to the dried drug. The material complies with the monograph of the Deutscher Arzneimittel-Codex [Wallnussblätter - Juglandis folium, 2023].

CONSTITUENTS

Characteristic constituents are ellagitannin-type tannins (approximately 10%) and flavonoids (approximately 3%, mainly quercetin, kaempferol, hyperoside and their derivatives) [Amaral 2004; Pereira 2007; Zhao 2014; Suschke 2014; Lichius 2016]. Phenolcarbonic acids e.g. caffeic, vanillic, ellagic and chlorogenic [Amaral 2004; Pereira 2007; Amaral 2008; Gutiérrez Ortiz 2018]. The contents of phenolic compounds in young leaves are higher than their amounts in the mature leaves [Salimi 2012; Cosmulescu 2012]. Further characteristic compounds include diarylheptanoids, juglone derivates, anthraquinones, megastigmanes and oligomeric proanthocyanidins [Forino 2016; Schwindl 2019].

Fresh leaves contain reduced naphthoquinones as glycosides and aglycones [Babula 2009], the major aglycone is juglone [Lichius 2016]. Glycosides are cleaved enzymatically to aglycones [Morant 2008]. Juglone is an unstable compound which is easily polymerized to pigments (from yellow to black), therefore in dry leaves, juglone is present only in traces and in some extracts prepared from the dry plant material it is undetectable [Amaral 2004; Lichius 2016].

Other constituents are traces of essential oil including monoterpenes α- and β-pinene [Fojtova 2008], sesquiterpenes including caryophyllene and germacrene D [Nahrstedt 1981; Buttery 1986; Farag 2008; Boukhari 2013]; organic acids including malic acid, shikimic acid, citric acid and ascorbic acid [Santos 2013].

CLINICAL PARTICULARS

Therapeutic indications
Minor inflammatory conditions of the skin, excessive perspiration of hands and feet [Jänicke 2003; Bäumler 2007]

In these indications, the efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adult daily dose: 4-6 g of the comminuted herbal substance in 200 mL of boiling water as a decoction. To be applied topically as a compress or a partial bath [Suschke 2014, Schilcher 2016; Lichius 2016].

Method of administration
For cutaneous application.

Duration of use
No restriction.

Contraindications
Open wounds and extensive skin injuries. Not to be applied as an occlusive treatment [Bonamonte 2001; Suschke 2014; Corazza 2019].

Special warnings and special precautions for use
Topical application to large areas should be avoided. In rare cases, contact dermatitis may occur [Bonamonte 2001; Suschke 2014; Corazza 2019].

E/S/C/O/P MONOGRAPHS

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
None reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Hypoglycaemic activity
A dry methanolic extract (DER 4-6:1) was investigated for hypoglycaemic activity by assessing its effect on glucose uptake in C2C12 myocytes, protein tyrosine phosphatase 1B (PTP1B) inhibition and peroxisome proliferator-activated receptor gamma (PPARγ) activation. The extract enhanced the glucose uptake rate at 25 µg/mL compared to untreated cells. This activity may partly be explained by the inhibition of PTP1B in a concentration range of 10 to 100 µg/mL. PPARγ was not affected by the extract in the same range [Pitschmann 2014].

In an activity-guided isolation, two megastigmanes were shown to affect glucose uptake in HepG2 and Caco-2 cells. (3S,5R,6R,7E,9S)-3,5,6,9-tetrahydroxymegastigman-7-ene significantly ($p<0.001$) increased the uptake in HepG2 cells at 0.05 µg/µL, whereas 3,6,9-trihydroxymegastigman-7-ene was more effective in Caco-2 cells [Forino 2016].

Antioxidant and radical scavenging activity
The radical scavenging activities of acetone, ethyl acetate and methanolic extracts (not further specified) were assessed at a concentration of 62.5 µg/mL in the DPPH assay. The methanolic extract was the most effective DPPH radical scavenger with an inhibition of 67.8% [Miliauskas 2004].

A lyophilised 40% ethanolic extract (not further specified) demonstrated scavenging activity against all the reactive species tested. IC_{50} values for the ROS $O_2^{\bullet-}$ and H_2O_2 were 47.6 and 383 µg/mL respectively [Almeida 2008].

The antioxidant activities of methanolic and petroleum ether extracts (yield 27.7% and 1.1% respectively) were assessed by their ability to inhibit oxidative haemolysis of human erythrocytes induced by 2,2´-azobis(2-amidinopropane) dihydrochloride (AAPH). Under the oxidative action of AAPH, only the methanolic extract significantly ($p<0.05$) protected the erythrocyte membrane from haemolysis (IC_{50} 0.06 mg/mL) [Carvalho 2010].

A methanolic extract exhibited greater antioxidant activity than a decoction (not further specified). Respective EC_{50} values were 65.91 µg/mL vs. 78.97 µg/mL for DPPH scavenging activity, 75.87 µg/mL vs. 83.71 µg/mL for reducing power, 189.92 µg/mL vs. 269.27 µg/mL for µ-carotene bleaching inhibition and 20.36 µg/mL vs. 114.68 µg/mL for TBARS inhibition [Santos 2013].

A dry 95% ethanolic extract (yield 7.93%) had an ORAC value of 2543.5 trolox equivalents/g and reducing power with an IC_{50} value of 121.7 µg/mL [Wang 2015].

Enzyme inhibitory activity
The mushroom tyrosinase inhibitory activity of a dry 80% methanolic extract containing 16.25% ellagic acid was tested by monitoring the formation of dopachrome, an intermediate in melanogenesis. The IC_{50} of the extract was 505 µg/mL [Oezer 2007].

An aqueous dry extract (DER 8.65:1) inhibited acetylcholinesterase and butylcholinesterase by 40.09 and 56.23% respectively at a concentration of 0.1 mg/mL [Karakaya 2019].

Antibacterial activity
The antimicrobial activities of a purified extract (acetone–water 2:1) against acne-promoting microorganisms were determined using the disk diffusion method and compared to tea tree oil, doxycycline and clindamycin. The extract at concentrations of 10-20% exhibited significantly ($p<0.02$) larger inhibition zones than tea tree oil at concentrations of 10 to 20% when tested against *Propionibacterium acnes* and *Staphylococcus epidermidis*. Whereas only the 15% concentration extract had significantly ($p<0.03$) greater antimicrobial activity than tea tree oil against *S. aureus*. The extract had comparable activity with doxycycline (5 µg) or clindamycin (2 µg) against *Staphylococcus* species but less activity against *P. acnes*. There were considerably lower levels of microbial resistance for the extract than for tea tree oil [Qa'dan 2005].

A 75% ethanolic extract (not further specified) was active against *L. monocytogenes*, *L. ivanovii* and *L. murrayi* with IC_{50} values of 12.5, 25 and 12.5 µg/mL respectively [Altanlar 2006].

Lyophilized water extracts (not further specified) selectively inhibited the growth of Gram positive bacteria (*Bacillus cereus*, *B. subtilis*, *S. aureus*) with *B. cereus* being the most susceptible (MIC 0.1 mg/mL). The extracts were not active against Gram-negative strains [Pereira 2007].

A methanolic extract (not further specified) exhibited an antimycobacterial effect against *M. tuberculosis* strain H37Rv with an MIC of 125 µg/mL [Cruz-Vega 2008].

The hydrodistilled essential oil exhibited broad spectrum inhibition against all the bacteria tested, with Gram-positive strains (*S. epidermidis* MTCC-435, *Bacillus subtilis* MTCC-441, *S. aureus*; MIC 15.62 µg/mL) being more susceptible than Gram-negative (*Proteus vulgaris* MTCC-321, *Pseudomonas aeruginosa* MTCC-1688, *Salmonella typhi*, *Shigella dyssenteriae*, *Klebsiella pneumoniae* and *E. coli*; MIC 31.25-62.50 µg/mL) [Rather 2012].

A 70% ethanolic extract (not further specified) was active against *Staphylococcus epidermidis* with an MIC of 156.25 µg gallic acid equivalents/mL [Nicu 2018].

Antifungal activity
The antifungal activity of an 80% methanolic extract (not further specified) was evaluated against nineteen *Candida* strains, including *C. albicans*, *C. glabrata*, *C. parapsilosis* and *C. tropicalis* species. The extract exerted an inhibitory effect against all the tested *Candida* strains (inhibition zones 9-13 mm), with an MIC_{50} value of 187.5 µg/mL for the most susceptible strain of *C. tropicalis* [Martins 2015].

Cardiovascular effect
An aqueous extract (not further specified) inhibited the maximal contractile response induced by noradrenaline on isolated rat

thoracic aorta in a concentration-dependent manner (IC_{50} 3.2 mg/mL) [Perusquía 1995].

Antiproliferative activity
A methanolic extract (yield 27.7%) was tested for antiproliferative activity using the human renal cancer cell lines A-498 and 769-P, and the colon cancer cell line Caco-2. The extract showed concentration-dependent growth inhibition towards all cell lines with IC_{50} values of 0.226, 0.352 and 0.229 mg/mL, respectively [Carvalho 2010].

A methanolic extract and a decoction (not further specified) exhibited similar antiproliferative activity on breast (MCF-7), colon (HCT-15) and hepatocellular (HepG2) carcinoma cell lines (50% growth inhibition (GI_{50}) 209-285 µg/mL) [Santos 2013].

A hexane extract (not further specified) exhibited dose-dependent antiproliferative activity against PC3 human prostate cancer cells in the concentration range of 5-100 µg/mL with an IC_{50} value of 48.4 µg/mL, and induced significant ($p<0.05$) apoptosis [Li 2015].

Bioassay-guided fractionation of a chloroform extract led to the isolation of 5-hydroxy-3,7,4′-trimethoxyflavone, lupeol, daucosterol, 4-hydroxy-α-tetralone, β-sitosterol, 5,7-dihydroxy-3,4′-dimethoxyflavone and regiolone. All compounds inhibited proliferation of MCF-7 and BHY cells in a concentration-dependent manner. 5,7-Dihydroxy-3,4′-dimethoxyflavone and regiolone showed cytotoxic effects on MCF-7 and BHY cells (IC_{50} 21–51 µM) yet were not toxic to normal NIH3T3 fibroblasts. MCF-7 growth inhibition was attributed to apoptosis. The caspase cascade was not involved in the apoptosis [Salimi 2014].

In vivo experiments

Antidiabetic effect
An 80% ethanolic extract (DER 1:16.9) and a water decoction (DER 1:20) were administered orally to mice and assessed in the oral glucose tolerance test. While the ethanolic extract increased glycaemia, the decoction exhibited hypoglycaemic activity [Neef 1995].

Sprague Dawley rats with alloxan-induced diabetes were fed a diet supplemented with 60 g/kg b.w./day dry walnut leaf for 15 days, while an untreated diabetic group and a non-diabetic group received only the standard diet. Walnut leaf reduced the blood glucose level significantly compared with the untreated diabetic group (9.03 vs. 14.36 mmol/l, $p<0.05$). The decreased volume density of islets in pancreatic tissue, percent of β cells and islets size in untreated diabetic control rats was improved by the supplementation [Jelodar 2007].

The effects of an aqueous extract on serum glucose and lipid levels were reported in two similar studies each involving male Wistar albino rats divided into three groups, a healthy control group and two groups with streptozotocin-induced diabetes. One of the diabetic groups also received the extract (400 mg/kg p.o.) for 4 weeks. The extract significantly ($p<0.05$) attenuated the diabetes-induced increases in glucose, triglycerides, cholesterol, LDL-C and the induced decrease in HDL-C. The LDL-C/HDL-C ratio and total cholesterol/HDL-C ratio were also significantly ($p<0.05$) decreased compared with the diabetic control group [Gholamreza 2008; Divband 2010].

An ethanolic extract (not further specified) was examined in male Wistar rats divided into four groups: non-diabetic rats, alloxan-induced diabetic rats with no treatment, alloxan-induced diabetic rats treated with an ethanolic extract (200 mg/kg) and alloxan-induced diabetic rats treated with glibenclamide (0.6 mg/kg). All treatments were administered intraperitoneally for 4 weeks. Diabetes induction with alloxan was carried out 2 weeks before starting the treatment. Blood samples were collected three times: before injection of alloxan (Time 0), at 2 weeks (Time 1) and at 6 weeks (Time 2) to determine glycosylated haemoglobin (HbA1C), insulin, glucose, cholesterol, LDL-C, HDL-C, VLDL-C and triglycerides. At Time 1 the levels of blood glucose, cholesterol, VLDL-C and LDL-C were increased ($p<0.05$) and the levels of HDL-C and plasma insulin decreased ($p<0.05$) in all diabetic rats compared to Time 0 and non-diabetic rats. At Time 2, the extract as well as glibenclamide resulted in decreases ($p<0.05$) in blood glucose along with an increase in the insulin level. Serum cholesterol, triglycerides, LDL-C, and VLDL-C levels were decreased in the glibenclamide and the extract groups in comparison with Time 1. In the extract group, the LDL-C level decreased compared to diabetic control ($p<0.05$). The HDL-C level was raised with both the extract and glibenclamide and showed no significant difference when compared with the non-diabetic group and Time 0 values. HbA1C in diabetic control rats was significantly higher ($p<0.05$) compared with non-diabetic rats. The extract and the glibenclamide groups had lower mean HbA1C levels, which were not significantly different compared with the non-diabetic group and Time 0 values. The extract and glibenclamide attenuated the diabetes-induced changes in a comparable manner, bringing values back to near those of the non-diabetic controls. A histological study at Time 2 revealed that the size of islets of Langerhans enlarged to almost normal size in both treated groups as compared with diabetic rats with no treatment [Asgary 2008].

Alloxan-induced diabetic male Wistar rats were treated orally with a 70% methanolic extract (yield 17%) at doses of 250 (I) or 500 mg/kg (II), acarbose 20 mg/kg (III) or vehicle (IV) and normal rats treated with vehicle alone (V). The postprandial blood glucose level was examined after a single dose and after three weeks of daily treatment. The extract had a significant hypoglycaemic effect in both short- and long-term models. Post-prandial glucose levels were at their lowest 8 hours after the single oral dose, with a significant ($p<0.0001$) reduction in glucose of 53% in goup III, 40% in group I and 29% in group II as compared to group IV. After 3 weeks of treatment, post-prandial glucose levels had significantly ($p<0.0001$) decreased by 27% in group I and 43.7% in group III as compared to group IV. There was no change in the insulin and glut-4 gene expression [Teimori 2010].

The antidiabetic effect of a 90% ethanolic extract (DER 8.7:1) was studied in diabetic Wistar rats. Group I were healthy controls fed a normal diet, while diabetes was induced with streptozotocin in groups II, III and IV. The extract was administered orally to groups III and IV at 200 and 400 mg/kg b.w. respectively for 28 days. Treatment with the extract resulted in significant ($p<0.05$) and dose-dependent reductions in blood glucose, glycosylated haemoglobin, LDL, triglycerides and total cholesterol as compared to the diabetic control group (II), with the higher dose reducing levels to those comparable with the healthy control group. Only at the higher dose were insulin and HDL significantly ($p<0.05$) increased compared to group II [Mohammadi 2011].

The effects on blood glucose and lipids of oral administration of a 90% ethanolic extract (DER 8.7:1) were investigated in rats with diabetes induced by streptozotocin-nicotinamide. The rats were divided into six groups, treatments commenced one week after induction of type II diabetes and continued for 4 weeks. Group I: healthy control; II: healthy control receiving 200 mg/kg extract; III: diabetic control; IV: diabetic animals receiving 200 mg/kg extract; V: diabetic animals receiving 400 mg/kg extract; VI: diabetic animals receiving 500 mg/kg metformin). Dose-dependent reductions of fasting blood glucose levels, HbA1c (I: 6.46%; II: 6.20%; III: 13.58%; IV: 11.61%; V: 8.29%; VI: 6.38), total cholesterol (63.11; 61.36; 115.73; 71.33; 61.28; 64.27 mg/dL)

and serum triglycerides (75.28; 74.21; 159.66; 135.32; 89.30; 81.36 mg/dL) were detected after 4 weeks in rats treated with the extract and metformin as compared to the diabetic controls ($p<0.05$). No differences between groups I and II were observed in these parameters [Mohammadi 2012].

The effects of cyclohexane and ethanol extracts (not further specified) on blood glucose and sorbitol dehydrogenase activity were investigated in male Sprague-Dawley rats with diabetes induced with streptozotocin. The rats were divided into seven groups and treated orally for 30 days as follows: control and diabetic control, control cyclohexane and control ethanol (250 mg/kg b.w.), diabetic cyclohexane (250 mg/kg cyclohexane extract), diabetic ethanol 150 and diabetic ethanol 250 (150 and 250 mg/kg ethanolic extract respectively). The cyclohexane extract improved the blood glucose level compared to the other diabetic groups. Both extracts significantly ($p<0.05$) reduced the activity of sorbitol dehydrogenase compared to diabetic controls [Abbasi 2017].

The effects of a methanolic extract (200 mg/kg/day p.o.) were studied in rats with experimentally-induced diabetic nephropathy. One week after induction with streptozotocin the first group began treatment with the extract ("preventive") and at 5 weeks treatment with the extract started for a further group ("curative"). Rats received the extract or saline until the end of the 8th week. Both the "preventive" and the "curative" treatments attenuated the diabetes-induced histopathological changes in the kidney and significantly ($p<0.008$) decreased fasting blood sugar levels compared to the diabetic control group. Increased caspase-3, COX-2, PARP and iNOS expressions observed in diabetic rats were also significantly ($p<0.009$) attenuated by the treatment [Nasiry 2019].

Type II diabetes was induced in rats by administering streptozotocin and nicotinamide. One group was left untreated, a second group received 200 mg/kg/day p.o. of an ethanolic extract (DER 3.43:1), a third group was treated with 1000 mg/kg/day p.o. of metformin, while a fourth group served as a non-diabetic healthy control group. Fasting blood glucose levels decreased significantly ($p<0.05$) in the groups treated with the extract and metformin for 28 days compared to the untreated diabetic group. Average body weight decreased significantly ($p<0.001$) in the untreated diabetic group compared to those in the treated groups. Adiponectin and Fibronectin Type III Domain Containing 5 levels were significantly ($p<0.01$) increased in the treated groups as compared to diabetic controls [Uslu 2019].

Anti-inflammatory and antinociceptive effect
Ethanolic (DER: 4.8:1) and aqueous (DER: 4:1) extracts were evaluated for anti-inflammatory and antinociceptive activities in Swiss albino mice. Single oral doses of the extracts (500 mg/kg) demonstrated significant antinociceptive activity against p-benzo-quinone-induced abdominal contractions, with a 29.5% ($p<0.01$) and 67.9% ($p<0.001$) decrease in the number of writhings for the aqueous and ethanolic extracts respectively. Using the same dose, the ethanolic extract exhibited significant ($p<0.01$) anti-inflammatory activity against carrageenan-induced hind paw oedema without inducing any gastric damage [Erdemoglu 2003].

The effect of concurrent administration of an extract (not further specified) and morphine on analgesia was investigated in rats divided into seven groups (control, sham and five experimental groups). The first experimental group received 2 mg/kg of morphine, 3 further groups received 2 mg/kg of morphine concurrently with the extract at doses of 0.5, 1 and 1.5 mg/kg and the last group received only 1.5 mg/kg of the extract, all i.p. 15 minutes before the formalin test. Effects at minutes 0-5 and 15-60 were assessed for the acute and chronic phases of pain respectively. The extract at the dose of 1.5 mg/kg showed a dose-dependent nociceptive effect in the acute phase of the formalin test. Moreover, the extract significantly ($p<0.05$) enhanced the antinociceptive effect of morphine, especially in the acute phase of the formalin test [Mokhtari 2008].

In mice, antinociceptive activity was studied using hot-plate and writhing tests, and anti-inflammatory effects were studied using xylene-induced ear edema and cotton pellet tests. The aqueous (2.87 and 1.64 g/kg i.p.; $p<0.001$) and ethanolic (extracting solvent 85% ethanol, after defatting with petroleum ether, not further specified; 2.44 and 1.17 g/kg i.p.; $p<0.001$ and $p<0.01$ respectively) extracts showed significant antinociceptive activity in the hot-plate test. Pretreatment with naloxone (2 mg/kg, s.c.) did not inhibit the effect. The extracts (aqueous: 0.41 and 1.64 g/kg; ethanol: 0.292-2.044 g/kg) exhibited significant ($p<0.001$) antinociceptive activities in the writhing test, which were also not blocked by naloxone. In the xylene test, both extracts showed anti-inflammatory activity in distinct doses. The extracts showed anti-inflammatory activity against chronic inflammation in the cotton pellet test [Hosseinzadeh 2011].

Hepatoprotective effect
The hepatoprotective effect of a 40% ethanolic extract (not further specified) against carbon tetrachloride-induced liver damage was assessed in rats randomly divided into seven groups: control, CCl_4 (0.5 mL/kg b.w. i.p.), extract alone (0.2 g/kg b.w./day p.o.), and CCl_4 plus extract (0.05, 0.1, 0.2 and 0.4 g/kg b.w./day p.o.). After 28 days, liver damage was assessed by serum biochemical parameters (ALAT, ASAT, ALP and albumin), antioxidant enzymes (SOD and CAT) and histopathological parameters. Administration of the extract at 0.2 and 0.4 g/kg significantly ($p<0.05$) lowered ALAT, ASAT and ALP levels in CCl_4-treated rats. The extract increased SOD and CAT and reduced fatty degeneration of the liver, cytoplasmic vacuolization and necrosis in CCl_4-treated rats [Eidi 2013].

Sedative effect
Oral administration of a chloroform extract (DER 131.8:1) of fresh leaves and of juglone induced sedative activity in two mouse models (actimeter and sleep potentiation). Significant ($p<0.005$) increases in pentobarbital-induced sleep duration compared to control (olive oil) were observed in mice treated with the extract (2.89- and 1.64-fold for 6.5 and 3.25 mg/kg doses respectively) and juglone (2.47- and 1.5-fold for 0.125 and 0.0625 mg/kg respectively), as well as for diazepam (2 mg/kg p.o.; 3.71-fold). In the actimeter test, both the chloroform extract (3.25-26 mg/kg) and juglone (0.0625-0.5 mg/kg) significantly ($p<0.05$ to $p<0.005$) decreased motor activity compared to control [Girzu 1998].

Anthelmintic effect
Petroleum ether, methanol and water extracts (not further specified) were evaluated for their anthelmintic activity against adult Indian earthworms (*Pheretima posthuma*). Groups of worms were tested with extract concentrations of 10, 25 and 50 mg/mL, distilled water (control) or piperazine citrate (10 mg/mL in distilled water, positive control). All of the extracts showed dose-dependent activity. The methanolic extract demonstrated the greatest anthelmintic activity, and even at the lowest concentration (10 mg/mL) was comparable to piperazine citrate (time taken for paralysis 18.16 vs. 19.36 min) [Das 2011].

Clinical studies
The hypoglycaemic effect of a dry aqueous extract (not further specified) was investigated in a randomized, double-blind, placebo-controlled study involving 58 type II diabetes patients (40-65 years; inclusion criteria: HbA1C > 7%, fasting blood glucose level<250 mg/L, taking maximum dose of metformin and glibenclamide). One group (n=30; 11 M/19 F) received 2 × 200 mg extract daily while the other group (n=28; 12 M/16 F)

received placebo. Fasting blood samples were collected at the beginning of the study and after two months of treatment. The levels of HbA1c and blood glucose were determined as the main outcomes and insulin, SGOT, SGPT and ALP levels as secondary outcomes. Compared to baseline, there were significant decreases in serum fasting HbA1C (from 8.5% to 7.6%; p=0.000) and fasting blood glucose levels (from 165 mg/dl to 144 mg/dL; p<0.017) in the extract group. HbA1C but not glucose was also significantly (p=0.042) decreased in the placebo group. Insulin was significantly (p<0.007) increased in the extract group (from 8.6 U/l to 10.4 U/l) but not in the placebo group [Hosseini 2014a].

In a randomized, double-blind, placebo-controlled study, the effects of an extract (70% ethanol, DER 40:1) on hyperglycaemia and lipid profiles were investigated in 61 type II diabetic patients. Patients with fasting blood glucose between 150 and 200 mg/dL, glycated haemoglobin (HbA1c) between 7% and 9%, and aged between 40 and 60 years, were randomly divided into two groups. The first group (n=32; 15 M/17 F) received 100 mg dry extract two times a day for 3 months while the other group (n=29; 13 M/16 F) received placebo. The standard anti-diabetic therapy (metformin, glibenclamide, nutritional regimen) was continued in both groups. The extract group exhibited significant (p<0.05) decreases compared to baseline in levels of fasting blood glucose (165 mg/dL. vs. 143 mg/dL), HbA1c (8.51% vs. 7.52%), total cholesterol (192.15 mg/dL vs. 179.68 mg/dL) and triglyceride levels (162.53 mg/dL vs.146.38 mg/dL); the decreases were also significantly (p<0.05) greater than for placebo. There was no significant change in insulin level in either group. Patients in the verum group were significantly (p<0.05) more satisfied with the treatment, with 84.5% finding the treatment to be moderately, potently or very potently effective, compared with 3.4% of the placebo group [Hosseini 2014b].

In a randomized, double-blind, placebo-controlled trial, 40 diabetic patients received either 100 mg of a 70% ethanolic (DER 6.45:1) extract (n=20; 1 M/19 F) or placebo (n=20; 2 M/18 F) 2 times daily for 8 weeks. Blood glucose, HbA1c level, body weight, body mass index, blood pressure, lipid profile, serum insulin and insulin resistance were compared at the beginning and at the end of the study. Only body weight, body mass index and systolic blood pressure were significantly (p<0.05) decreased compared to baseline in the extract group. In the placebo (microcrystalline cellulose) group, postprandial glucose and HbA1c levels decreased significantly (p<0.05) compared to baseline. At the end of the study, there were no significant differences between the two groups in the observed end points [Rabiei 2018].

Pharmacokinetic properties
No data available.

Preclinical safety data

Acute toxicity
The role of cell-to-cell interactions in herbal-induced liver toxicity was investigated in monocultures of human hepatocytes (HepG2) and in co-cultures of HepG2 cells and human monocytes (THP1). Cells were treated with various concentrations (1–500 µg/mL) of an aqueous extract for 24 h. In the MTT test, the extract reduced MTT formation by about 60% at a concentration of 500 µg/mL in HepG2 cells. There were no negative effects observed in the co-culture system for all concentrations of the extract. There were no significant changes of LDH levels in the culture medium seen after 24 h of exposure to the extract [Saad 2006].

The acute toxicity of an aqueous and an 85% ethanolic (not further specified) extract was evaluated after i.p. administration. The LD_{50} values were 5.5 and 3.3 g/kg b.w. respectively [Hosseinzadeh 2011].

A methanolic extract and a decoction (not further specified) did not exhibit cytotoxicity on non-tumour liver primary PLP2 cells (GI_{50} > 400 µg/mL) [Santos 2013].

Clinical safety data
In a randomized, double-blind, placebo-controlled study involving type II diabetic patients taking 2 × 200 mg/day of a dry aqueous extract (not further specified; n=30) or placebo (n=28), no differences in SGOT and SGPT levels were observed after 2 months of treatment and no gastrointestinal side effects were reported [Hosseini 2014a].

In a randomized, double-blind, placebo-controlled study involving type II diabetic patients receiving 2 × 100 mg dry extract (70% ethanol, DER 40:1; n=32) or placebo (n=29) daily for 3 months, only mild adverse effects occurred. At least one gastrointestinal event (especially mild diarrhoea at the beginning of the treatment) was experienced by 39% of the patients in the extract group versus 6% in the placebo group. Eleven patients in the extract group complained of mild adverse events at the beginning of the study, such as diarrhoea, vertigo and anxiety compared with 4 patients in the placebo group; general tolerability of the treatment within the groups was not statistically different. The mean values of the analysed laboratory parameters (ALT, AST, ALP, BUN and creatinine) did not significantly change during the trial [Hosseini 2014b].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (well-established use) or on experience and historical use of that product (traditional use) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me, on behalf of my colleagues in ESCOP, to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

LEONURI CARDIACAE HERBA 2019

Motherwort

DEFINITION

Motherwort consists of the whole or cut flowering aerial parts of *Leonurus cardiaca* L. It contains not less than 0.2% of flavonoids, expressed as hyperoside ($C_{21}H_{20}O_{12}$; M_r 464.4) and calculated with respect to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Motherwort].

CONSTITUENTS

The main characteristic constituents are flavonoids including glycosides of apigenin, kaempferol and quercetin [Kartnig 1985; Schulz 1973; Reuter 1970]; a C_{15}-iridoidglucoside, leonuride [Hänsel 1993; Weinges 1973; Schilling 1975], diterpenes of the labdane and clerodane types [Malakov 1985; Brieskorn 1979; Papanov 1998; Knöss 1998], caffeic acid-4-rutinoside [Tschesche 1980] and the phenylpropanoid lavandulifolioside [Milkowska-Leyck 2002].

Other constituents include the alkaloids stachydrine [van Eijk 1952] and leonurine [Gulubov 1970]. In a more recent study using a new HPLC method leonurine could not be detected [Kuchta 2012]. Triterpenes mainly ursolic acid [Schulz 1973; Kartnig 1985; Ali 2007], labdane type diterpenes [Agnihotri 2008], sterols [Senatore 1991] and volatile oil 0.01-0.2% [Mockute 2006; Morteza-Semnani 2008]. The main components in the oil are germacrene D, caryophyllene, α-humulene, epi-cedrole and dehydro-1,8-cineole. The composition depends on the chemotype and provenance [Morteza-Semnani 2008; Mockute 2006; Lawrence 1972].

CLINICAL PARTICULARS

Therapeutic indications
Mild cardiac complaints of nervous origin [Nahrstedt 1985; Wichtl 1990; Milkowska-Leyck 2002; Brayfield 2014, Kartnig 2014]. For this indication, the efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adults and children above 12 years
Dried drug: 4.5 g as an infusion (daily dose) [Czygan 2002, Kartnig 2014]; 2-4 g as dried drug or as an infusion three times daily [Bradley 1992].
Liquid extract (1:1, 25% ethanol): 2-4 ml three times daily [Bradley 1992; Czygan 2002].
Tincture (1:5, 25% ethanol): 4-10 ml three times daily [Bradley 1992].
Tincture (1:5, 34% ethanol): 2-6 ml three times daily [Czygan 2002].

Method of administration
For oral administration

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contra-indications
None known.

Special warnings and special precautions for use

Special warnings
None required.

Precautions for use
As with all cardiac complaints, consultation with a medical practitioner is essential before treatment.

E/S/C/O/P MONOGRAPHS

Interaction with other medicaments and other forms of interaction
None known.

Pregnancy and lactation
Leonurine showed a uterotonic effect on isolated rat uterus in concentrations from 4 µg/ml medium and above [Yeung 1977].

The product should not be used during pregnancy [Bradley 1992].

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antioxidant effects
The free radical scavenging and antioxidant activities of a methanolic dry extract of motherwort were demonstrated using the DPPH assay, the phosphomolybdenum assay and inhibition of linoleic acid peroxidation. In the DPPH assay, after 5 minutes the EC_{50} value was 0.80 µg/ml. In the phosphomolybdenum assay the activity was concentration dependent. At 40ºC the reducing capacity of the extract at 1 µg/ml and 20 µg/ml was equivalent to 1.35 µg/ml and 43.14 µg/ml of ascorbic acid respectively. In the linoleic acid peroxidation assay the extract at 100 µg/ml reduced lipid peroxidation by 73.3% [Matkowski 2006].

A hydroethanolic (70%; DER 1:5) fluid extract demonstrated an antioxidant and radical scavenging effect using DDPA and ABTS reaction systems. In the DDPA system, after 10 minutes the value was 84.89%. In the ABTS assay it was 88.28% [Bernatoniene 2009].

The same extract, with concentrations of 113.5 ng/mL - 2.3 µg/mL phenolic compounds, increased the state 2 respiration rate (10-38%) but did not affect the state 3 or uncoupled mitochondrial rate. The highest extract concentration, 18.2 µg/mL of phenolic compounds, induced an 85% increase in the state 2 respiration rate and a decrease in the state 3 respiration rate of 44% [Bernatoniene 2014].

The antioxidant effects of a dry acetone-water (30:70 v/v; DER 1:10) extract were assessed by the ABTS radical cation decolorization assay, the DPPH assay and the ferric reducing antioxidant power (FRAP) assay. Distilled water was used as a blank, Trolox as a standard and ascorbic acid as a positive control. The results expressed as Trolox equivalents ranged between 350-455 µM Trolox/g for the extract in the 3 assays. The results for ascorbic acid were 4896, 7180 and 4793 µM Trolox/g for the ABTS, DPPH and FRAP assays respectively [Sadowska 2017].

Effect on isolated rat heart
In the Langendorff model, a butanolic dry fraction from a methanolic dry extract significantly reduced coronary output of isolated rat heart at doses of 50-2000 µg ($p<0.05$ to 0.01). The heart rate was also significantly reduced at doses of 50-2000 µg ($p<0.05$ to 0.001). The electrocardiogram showed a marked prolongation of P-Q and Q-T intervals by 31-78% and 12-29% respectively [Milkowska-Leyck 2002].

Antimicrobial effects
A dry water fraction of an acetone-water (30:70 v/v; DER 1:10) extract was investigated for its antimicrobial, anti-adhesive and antibiofilm properties against *Staphylococcus aureus*. The MIC value of the extract was 6 mg/mL. The anti-adherence activity of the extract at a concentration of 75% MIC was 23.2-32.4%. There was no effect on biofilm formation [Micota 2014].

The same extract at concentrations of 75% MIC and 50% MIC resulted in the reduction of some important *S. aureus* characteristics: formatting of aggregates in plasma, adherence to a fibrin-coated surface, staphylocoagulase dependent plasma clotting, survival in human blood, α-toxin release and surface protein A expression. Tolerance to the exogene hydrogen peroxide was enhanced after pre-incubation with the extract [Micota 2016].

Other effects
In the $GABA_A$ receptor binding assay, a hydroethanolic (45%) dry extract bound to the GABA site and to the benzodiazepine site of rat $GABA_A$ receptors with IC_{50} values of 21 and 28 µg/mL (two independent measurements) for the GABA site and 646 and 372µg/mL for the benzodiazepine site [Rauwald 2015].

Various extracts of motherwort, a dry ethanolic 70% v/v extract, an aqueous dry extract refined by extraction with ethyl acetate and ethyl ether, and the ether phase of a methanolic extract, were tested on the oxidation of 5-thio-(2-nitrobenzoic acid) (TNB) to hypothiocyanite (OSCN). For the ethanol extract, the maximum OSCN production was observed at a concentration of 2 mg/ml, for the refined aqueous extract at 1 mg/ml and for the ether phase of the methanolic extract at 0.25 mg/ml [Flemmig 2015].

A dry acetone-water (30:70 v/v; DER 1:10) extract significantly ($p<0.01$) reduced arachidonic acid-induced platelet aggregation by 15% at a concentration of 100 µg/mL compared to control (no extract). The same extract at concentrations of 50, 100 and 350 µg/ml significantly ($p<0.05$) increased NO production in human umbilical vein endothelial cells (HUVECs). The extract at concentrations of 50 and 100 µg/ml reduced PAF secretion from HUVECs in the presence of *S. aureus* peptidoglycan (a PAF secretion stimulator) by 1.2-1.4 fold. No effects were observed at 350 µg/ml [Sadowska 2017].

In vivo experiments

Sedative effect
In mice, an undefined hydroalcoholic extract significantly ($p<0.05$) prolonged sleeping time induced by hexobarbital [Weischer 1994].

A butanolic dry fraction of a methanolic extract, administered to mice intragastrically at 800 mg/kg b.w., significantly ($p<0.01$) depressed spontaneous locomotor activity by 65% when compared to control animals receiving corresponding volumes of saline [Milkowska-Leyck 2002].

Analgesic effects
An undefined hydroethanolic extract, given to mice at i.p. doses of 500, 250 and 125 mg/kg b.w., demonstrated analgesic effects in various models. Saline at 0.5 ml and morphine at 10 mg/kg were used as negative and positive controls respectively. In the formalin test, the results were only significant compared to negative control at 500 mg/kg ($p<0.01$) in the early phase and at 250 mg/kg ($p<0.05$) in the late phase, with both results

comparable to morphine at 10 mg/kg. In the tail flick test, pre-treatment with the extract demonstrated a dose dependant and significant effect: 500mg/kg significantly ($p<0.01$) increased the antinociceptive activity 30-70 min after the injection; at 250 mg/kg and 125 mg/kg the effect was significant ($p<0.01$) after 45 and 60 minutes. In the hot plate test, the extract at 500 mg/kg significantly increased the latency response at 60 min ($p<0.05$) and at 75 and 90 minutes ($p<0.01$) [Rezaee-Asl 2014].

Clinical Studies
In an open study, 50 patients (male and female) with arterial hypertension stages 1 and 2, accompanied by anxiety and sleep disorders, were treated daily for 28 days with 4 capsules each containing 300 mg of a soybean oil extract of motherwort (1:10 w/v). Psychoneurological symptoms were rated on a 5 point SCAG scale; fatigue, reaction time and emotional condition on a 7 point numerical rating scale and a SAM (state-activity-mood) scale based on the answers of the patients to a questionnaire with 30 pairs of words. The symptoms, together with systolic and diastolic blood pressure, heart rate and EEG, were documented after 7, 14, 21 and 28 days. In the group of patients with stage 1 hypertension all parameters with the exception of heart rate were significantly ($p<0.05$) improved. The patients with stage 2 hypertension did not respond significantly to the treatment [Shikov 2011].

Pharmacokinetic properties
No data available.

Preclinical safety data

Acute toxicity
A butanolic fraction from a methanolic extract showed low toxicity. The intravenous LD_{50} in mice was > 400 mg/kg b.w. and the oral LD_{50} was > 2000 mg/kg b.w. [Milkowska-Leyck 2002].

Mutagenicity and carcinogenicity
A fluid extract, 1:1 in 35% ethanol, showed no mutagenic activity in the Ames mutagenicity test in *Salmonella typhimurium* TA 98 [Schimmer 1994].

Clinical safety data
In an open study of 50 patients with arterial hypertension, treated for 28 days with 1200 mg of an oil extract, side effects were minimal in all groups [Shikov 2011].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

LINI SEMEN

Linseed

2017

DEFINITION

Linseed consists of the dried ripe seeds of *Linum usitatissimum* L.

The material complies with the monograph of the European Pharmacopoeia [Linseed].

CONSTITUENTS

The seeds contain 3-9% of mucilage polysaccharides composed mainly of galacturonic acid, xylose, galactose and rhamnose units; 30-45% of fixed oil mainly consisting of triglycerides of α-linolenic (40-60%), linoleic and oleic acids; approx. 25% of protein; and 0.1-1.5% of cyanogenic glycosides such as linustatin and neolinustatin (the diglucosides of linamarin and lotaustralin, respectively) [El-Shattory 1976; Smith 1980; Schilcher 1980, 1986a,b; Leng-Peschlow 1993; Fedeniuk 1994; Teuscher 2016].

Glycosides of secoisolariciresinol as the major lignan, together with small amounts of matairesinol, isolariciresinol and pinoresinol [Sicilia 2003; Teuscher 2016]. Secoisolariciresinol and its glycosides are precursors of the mammalian phytoestrogens enterodiol and enterolactone [Axelson 1982; Adlercreutz 1984; Borriello 1985; Johnsson 2000; Teuscher 2016].

CLINICAL PARTICULARS

Therapeutic indications

Internal use

Treatment of habitual constipation or in conditions in which easy defecation with soft stool is desirable [Kurth 1976; Kay 1978; Jens 1981; Schilcher 1986a; Brunton 1990; Weiss 1997; Schilcher 2010; Teuscher 2016].

Supportive treatment of dyslipidaemia [Jenkins 1999; Dodin 2005; Patade 2008; Zhang 2008; Pan 2009b; Fukumitsu 2011; Almario 2013; Khalatbari 2013; Edel 2015] and hypertension [Rodriguez-Leyva 2013; Khalesi 2015; Machado 2015; Ursoniu 2015].

As a demulcent preparation for the symptomatic short-term treatment of gastritis and enteritis [Schilcher 1986a; Grützner 1997; Weiss 1997; Schilcher 2010; Teuscher 2016] and the symptomatic relief of irritable bowel syndrome [Kay 1978; Brunton 1990]. Supportive therapy for symptoms of diverticulosis [Kay 1978; Brunton 1990]. In all of these three indications, efficacy is plausible on the basis of human experience and long-standing use.

External use

Supportive treatment for symptoms of painful skin inflammations [Evans 1996; Weiss 1997]. The efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adults and children over 12 years of age

Internal use

As a laxative: 5 g of whole, finely-cracked or freshly crushed seeds, soaked in water and taken with a glassful of liquid three times daily. The effect starts 18-24 hours later [Schilcher 1986a, 1990; Weiss 1997].

Supportive treatment of dyslipidaemia and hypertension: 20-50g daily [Jenkins 1999; Dodin 2005; Patade 2008; Zhang 2008; Pan 2009b; Fukumitsu 2010; Almario 2013; Khalatbari 2013; Rodriguez-Leyva 2013; Edel 2015; Khalesi 2015; Machado 2015; Ursoniu 2015].

E/S/C/O/P
MONOGRAPHS

As a demulcent for gastritis and/or enteritis: for a mucilaginous preparation soak 5-10 g of whole linseed in 150 mL water and filter after 20-30 minutes [Weiss 1997; Teuscher 2016].

Topical use
30-50 g of crushed or powdered seed (may be de-fatted) as a warm poultice or warm compress [Weiss 1997].

Children from 6 to 12 years of age: half the adult dose [Kooperation Phytopharmaka 1998].
Children under 6 years of age: to be treated under medical supervision only.

Method of administration
For oral administration or cutaneous application.

Duration of use
Because of the gradual mode of action of bulk-forming laxatives, treatment should be continued for a minimum of 2-3 days to ensure optimum benefit [Reynolds 1993].

If abdominal pain occurs, or if there is no response after 48 hours, use of linseed should be discontinued and medical advice should be sought.

Contraindications
Atonic and obstructive ileus, subileus or conditions likely to lead to intestinal obstruction. Acute abdominal pain of any origin (e.g. appendicitis) [Brunton 1990; Teuscher 2016].

Special warnings and precautions for use
Linseed (whole, finely-cracked or freshly crushed) should be soaked and taken with at least 10 times the amount of fluid, otherwise compaction and intestinal obstruction may occur [Van Olffen 1982; Hardt 1986].

Persons with weight problems should take linseed whole, not cracked, because of its rich energy content of about 470 kcal (1960 kJ)/100 g].

Interaction with other medicinal products and other forms of interaction
The absorption of other medications taken at the same time may be delayed [Jenkins 1978; Lorenc-Kubis 2001].

Diabetics should be aware of a potential delay in glucose absorption [Jenkins 1976, 1978; Holt 1979; Munoz 1979; Vaaler 1980].

Pregnancy and lactation
There is a lack of sufficient data [Basch 2007]. In accordance with general medical practice, the product should not be used during pregnancy without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Reactions of hypersensitivity may occur very rarely [Alonso 1996; Alvarez-Perea 2013].

Overdose
In spite of its content of cyanogenic glycosides, single doses of up to 150-300 g of powdered linseed are not toxic. Health risks are not to be expected [Schilcher 1979, 1986; Anon 1983; Schulz 1983; Czygan 1984; Leng-Peschlow 1993; Weiss 1997; Teuscher 2016].

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Oestrogenic effects
Lignan precursors found in linseed are converted by bacteria present in the colon to metabolites interfering with the metabolism and activity of oestrogens [Borriello 1985]. Oestrogenic effects can be deduced from the effects on oestrogen receptor positive cancer cell lines [Lehraiki 2010; Richter 2010].

α-Amylase and α-glucosidase inhibiting activity
The inhibitory effects of various concentrations of a linseed extract (not further specified), secoisolariciresinol diglucoside (SDG) and secoisolariciresinol (SECO), enterodiol and enterolactone on the activities of α-glucosidase (soluble and immobilised) from rat intestine and α-amylase (soluble) from porcine pancreas were evaluated. Acarbose was used as positive control. The extract as well as SDG, SECO, enterodiol and enterolactone reduced the α-amylase activity. The extract inhibited both soluble α-glucosidase and α-amylase in a dose-dependent manner. The most active compound was enterodiol [Hano 2013].

Anti-proliferative effects
Trophoblast Jeg3 tumour cells were incubated for 48 hours with 2 different concentrations of linseed extract (not specified) and 7 fractions thereof. Cell proliferation as well as the concentrations of human chorionic gonadotropin (hCG) and progesterone produced by the tumour cells were measured. Proliferation of the Jeg3 cells was decreased by four different fractions in a dose-dependent manner, as well as the inhibition of hCG production by four fractions. Two fractions decreased the production of progesterone by 58% to 86%. Other fractions showed a stimulating effect on hormone production and cell proliferation [Waldschläger 2005].

The ability of isolated SECO, anhydrosecoisolariciresinol and of SDG (1 to 100 µM) to modulate the growth of human breast cancer cell lines (MCF-7 and MDA-MB-231) was assessed. Cells were incubated with 100 µL of oestrogen-free medium. After a 24-hour starvation period the cells were exposed to the test compounds for 48 hours. The strongest effect was observed for anhydrosecoisolariciresinol, which significantly decreased cell growth at 50 ($p<0.05$) and 100 pM ($p<0.001$) [Lehraiki 2010].

Enterolactone inhibited actin-based cell motility of MCF-7 and MDA MB 231 cells as evidenced by confocal imaging of a cell migration assay. The results are supported by the observation that the enterolactone down-regulated the metastasis-related metalloproteinases MMP2, MMP9 and MMP14 gene expressions. No significant alteration in the MMP11 gene expression was found [Mali 2012].

After addition of enterodiol or enterolactone, oestradiol-induced VEGF secretion in MCF-7 cells decreased significantly without agonistic effects ($p<0.01$). The elevated VEGF secretion following addition of oestradiol increased the expression of VEGF receptor-2 in umbilical vein endothelial cells, suggesting a pro-angiogenic effect of oestradiol by two different mechanisms, both of which were inhibited by the addition of lignans [Bergman Jungeström 2007].

Radioprotective effect
The radioprotective efficacy of SDG was investigated in murine

lung cells. Cells were pre-treated with SDG (50 μM) at various times (0 h, 2 h, 4 h and 6 h) prior to 2 Gy radiation exposure. Pre-treatment significantly ($p<0.05$) inhibited comet tail length, an indication of decreased DNA damage. Maximum protection was observed at 6 h of SDG treatment. Radiation-induced DNA single- and double strand breaks decreased and the overall cell survival improved. SDG significantly ($p<0.05$) increased gene and protein levels of antioxidant heme oxygenase-1, glutathione S-transferase mu 1 and NAD(P)H dehydrogenase quinone 1 [Velalopoulou 2016].

In vivo experiments

Effect on blood lipid levels

The effect of SDG was investigated in rabbits receiving either their normal diet (control group, n=8), a control diet supplemented with SDG (15 mg/kg b.w./day, n=5), a diet containing cholesterol (1%, n=6) or cholesterol + SDG (1% cholesterol + SDG 15 mg/kg b.w./day, n=5). Blood samples were collected before the experiment, and after 4 and 8 weeks, then the aorta was removed for assessment of atherosclerotic plaques, aortic malondialdehyde (MDA) and aortic tissue chemiluminescence (a marker for antioxidant reserve). Serum total cholesterol (TC), LDL-cholesterol (LDL-C) and the ratios of LDL-C/HDL-cholesterol (HDL-C) andTC/HDL-C increased in the 3rd and 4th groups. SDG significantly reduced TC and LDL-cholesterol by 33 and 35% respectively at week 8 ($p<0.05$), and significantly increased HDL-C by >140% at week 4 ($p<0.05$). It also decreased TC/HDL-C and LDL-C/HDL-C ratios significantly by approximately 64% ($p<0.05$). Comparing atherosclerotic plaques in the 3rd and 4th groups, it was found that SDG significantly reduced hypercholesterolaemic atherosclerosis by 73% ($p<0.05$). The increases in aortic malondialdehyde and chemiluminescence were significantly lower in the 4th group ($p<0.05$) [Prasad 1999].

In a similar study, rabbits were treated slightly differently: Group I, control; Group II, lignan complex (containing 34-38% SDG, 9.6-11% 3-hydroxy-3-methylglutaric acid (HMGA) and 15-21% cinnamic acids; 40 mg/kg b.w. daily p.o.); Group III, 0.5% cholesterol; Group IV, 0.5% cholesterol diet + lignan complex, (40 mg/kg b.w. daily p.o.). Rabbits in Group III developed atherosclerosis: 50.84 ± 6.23% of the intimal surface of the aorta was covered with atherosclerotic changes, associated with an increase in triglycerides, TC, LDL-C, HDL-C, MDA and aortic MDA and antioxidant reserve. The lignan complex reduced the development of atherosclerosis by 34%, with associated decreases in serum TC by 20%, LDL-C by 14%, TC/HDL-C by 34%, serum MDA by 35% and aortic MDA by 58%. HDL-C was increased by 30% in hypercholesterolaemic rabbits and by 25% in normocholesterolaemic rabbits with the lignan complex. The lignan complex did not affect TC, LDL-C and serum MDA, but did increase the aortic MDA, in the normocholesterolaemic rabbits [Prasad 2005].

The effects of ground linseed on plasma and hepatic lipids, and hepatic gene expression, in male and female human apolipoprotein B-100 transgenic (hApoBtg) mice, as well as in mice lacking the LDL receptor and apolipoprotein B mRNA editing enzyme complex 1 ($LDLr^{-/-}$/$apobec^{-/-}$ mice), were examined. The control diet containing 0.1% cholesterol and 30% kcal as fat was fed for 10 days to hApoBtg mice and for 14 days to $LDLr^{-/-}$/$apobec^{-/-}$ mice. Animals from each genetic background were then divided into 2 groups based on gender and mean plasma TC. The hApoBtg and $LDLr^{-/-}$/$apobec^{-/-}$ mice either continued on the control diet for a total of 31 and 35 days respectively, or were fed 20% w/w ground linseed with comparable caloric, macronutrient and fibre content for 21 days. Blood was obtained after a 4 hour fast from all mice prior to feeding both control and linseed diets, and after 10 and 21 days on the linseed diet. The control diet increased TC by >100 mg/dL in the hApoBtg mice with a greater increase in males and by 800 mg/dL in $LDLr^{-/-}$/$apobec^{-/-}$mice. After 3 weeks, the linseed diet significantly reduced plasma TC by 19% and 22% in hApoBtg and $LDLr^{-/-}$/$apobec^{-/-}$ mice respectively and non-HDL cholesterol by 24% in both models (p for all <0.05). Linseed significantly ($p<0.05$) reduced hepatic cholesterol by 32% and 47% in male and female hApoBtg mice respectively and by 66% in $LDLr^{-/-}$/$apobec^{-/-}$ mice. Linseed had no effect on the expression of the hepatic genes: LDLr, 3-hydroxy-3-methylglutaryl (HMG) CoA reductase, phospholipid transfer protein, cholesterol 7α hydroxylase, fatty acid synthase and acyl CoA oxidase in either mouse model [Pellizzon 2007].

Male Wistar rats (n=24) aged 21 days were divided into 3 groups: the control group received a casein-based chow (10% protein; 5% fibre; 7% lipid); the linseed group was fed with the casein-based chow supplemented with 25% linseed (10% protein; 7% fibre; 11% lipid) and the modified control group with the casein-based chow plus soybean oil and cellulose fibre (10% protein; 7% fibre; 11% lipid). After 180 days blood was taken and the vasodilator effect of acetylcholine (1-100 pmol) was evaluated in the preconstricted isolated rat mesenteric arterial beds. The linseed group showed a 47% increase in HDL-C, a 22% reduction in LDL-C, a 23% reduction in triglycerides and an increased ($p<0.05$) vasodilator response to acetylcholine as compared to the control group and modified control group [Daleprane 2010].

For 14 weeks, 140 LDL receptor-deficient mice received one of 14 experimental diets, containing either a regular (pork/soy) or trans fat source at a concentration of either 4 or 8%, with the addition of either dietary cholesterol (2%), whole ground linseed (10%) or one of the components of linseed (linseed oil rich in α-linolenic acid, partially defatted ground linseed (fibre) or lignan (SDG)). Adding ground linseed to the diet partially mitigated the rise in circulating cholesterol levels induced by the cholesterol-enriched diet. Atherosclerosis was stimulated by trans fatty acids and/or cholesterol. Addition of ground linseed to an atherogenic diet significantly ($p<0.05$) reduced atherosclerosis compared with the groups that consumed only the cholesterol and/or trans fatty acids. Of the tested components, only α-linolenic acid inhibited the atherogenic effect of cholesterol and/or trans fatty acids [Bassett 2011].

A linseed lignan concentrate (40mg/g SDG) showed a dose-dependent decrease in TC ($p<0.001$), triglycerides andVHDL in Triton WR 1339-induced hyperlipidaemic rats [Zanwar 2012].

Female Golden Syrian hamsters were either sham-operated or ovariectomised and randomly assigned to one of four treatment groups (n=12) for 90 days. Hamsters received either a semipurified diet or the same diet supplemented with either whole linseed or linseed oil (amount equivalent to the oil content of whole linseed). Whole linseed, but not linseed oil, significantly ($p<0.05$) prevented the ovariectomy-induced increase in serum total cholesterol (12% and 4% reduction by whole linseed and linseed oil respectively). There were no significant differences among groups in serum triglyceride concentration and liver lipids. Both whole linseed and linseed oil more than doubled the hepatic protein levels of 7α-hydroxylase in comparison to the ovariectomised animals receiving the control diet ($p<0.05$) [Lucas 2011].

Effects on β-glucuronidase activity

Six groups of Sprague-Dawley rats were fed one of the following diets for 100 days: a basal high-fat diet (20% fat), the basal diet supplemented with 2.5 or 5% of linseed, the basal diet

supplemented with 2.5 or 5% of defatted linseed, or the basal diet with a daily dose of 1.5 mg of SDG. All rats were injected with a single dose of azoxymethane (15 mg/kg b.w.) one week before treatment. Urinary lignan excretion, an indicator of mammalian lignan production, significantly increased in both the linseed groups and in the low-dose defatted linseed group ($p<0.0003$, $p<0.0001$ and $p<0.0001$ respectively) compared to the control. The total activity of caecal β-glucuronidase significantly increased in a dose-dependent manner in both the defatted linseed groups and in the high-dose linseed group ($p<0.01$, $p<0.047$ and $p<0.0004$ respectively). Compared to control the number of aberrant crypts per focus was significantly reduced ($p<0.01$ to $p<0.04$) in the distal colon of the five groups of treated rats. Four microadenomas and two polyps were observed in the control group but none in the treated groups. The total activity of β-glucuronidase was positively correlated with total urinary lignan excretion ($r=0.280$, $p<0.036$, $n=60$), and negatively with the total number of aberrant crypts ($r=-0.330$, $p<0.010$, $n=57$) and the total number of aberrant crypt foci ($r=-0.310$, $p<0.018$, $n=57$) in the distal colon. There were no significant differences between linseed and corresponding defatted linseed groups [Jenab 1996].

Antidepressant effects
The antidepressant effect of SECO on ovariectomised mice was investigated in the forced swimming test and the tail suspension test. After intragastric administration for 14 consecutive days at doses of 5, 10 and 20 mg/kg, SECO at 10 mg/kg significantly ($p<0.01$) reduced the duration of immobility in these two models as compared to control. The effect was similar to the positive control imipramine. In addition, SECO at doses of 10 and 20 mg/kg substantially increased brain noradrenaline and dopamine levels in ovariectomised mice [Wang 2013].

Effects on BPH
Forty male Wistar rats were divided into five groups: untreated control; treatment with testosterone propionate (TP) to induce prostate enlargement; TP-treated groups fed diets containing either 5% or 10% milled linseed; and TP-treated group fed a diet containing 20 ppm finasteride. Co-administration of linseed or finasteride with TP significantly reduced prostatic VEGF, epithelial cell proliferation and RNA/DNA ratio, and also significantly ($p<0.05$) increased the serum testosterone and testosterone/estradiol ratio compared to treatment with TP alone [Said 2015].

Male Wistar-Unilever rats were randomly divided into four groups of 12 rats each: a negative control, a positive control receiving daily s.c. TP and two verum groups receiving daily s.c. injections of TP and either 0.5% or 1.0% of a lignan-rich extract from linseed hulls in their diet. Treatment started 2 weeks before the induction of BPH and was continued for 5 consecutive weeks. The influence of TP and the lignan-rich extract on body weight, food and water consumption, and enterolactone levels in serum and urine was examined after 5-weeks. In a dose dependent manner, the extract significantly inhibited TP-induced increase in prostate size in comparison with positive controls ($p<0.001$). Higher serum and urine levels of enterolactone correlated with the extract dose [Bisson 2014].

Anti-proliferative effects
The effects of linseed oil fed to female mice as 10% of their diet were compared to corn oil. The respective diets were fed for 3-8 weeks prior to subcutaneous injections of one of two syngeneic mammary tumour cell types (410 and 410.4). The growth of 410.4 mammary tumours was significantly lower in mice given linseed oil than in animals given corn oil ($p<0.05$). Linseed oil also significantly enhanced incorporation of n-3 fatty acids into tumours ($p<0.005$) and significantly reduced tumour prostaglandin E production ($p<0.005$) compared to corn oil [Fritsche 1990].

Supplementation of a high-fat diet (20% corn oil) fed to 70 female rats for 4 weeks with either linseed flour or defatted linseed (5% and 10%) reduced epithelial cell proliferation by 38.8-55.4% and nuclear aberrations by 58.8-65.9% in mammary glands, optimum effects being observed with 5% linseed flour [Serraino 1991].

Five groups of 7 male rats were fed the same diet supplemented in the same manner for 4 weeks following a single injection of azoxymethane at 15 mg/kg b.w.. In the descending colon of the supplemented groups, the total number of aberrant crypts and foci were significantly reduced ($p<0.05$) by 41-53% and 48-57% respectively. The labelling index (the number of labelled cells, or cells undergoing DNA synthesis, per 100 cells in the epithelia of crypts from each section of the rat colon) was 10-22% lower in these groups, except for the 5% linseed meal group [Serraino 1992a].

In a long-term experiment, two groups of 60 female rats were fed the same high-fat diet, in one group the diet was supplemented with 5% linseed flour. After 4 weeks, tumours were induced in 44 rats by a single dose of 5 mg of 7,12-dimethylbenz[a]anthracene. After an additional week, half of the the group fed the basal diet received the supplemented diet for 20 weeks, while half of the group previously supplemented received the basal diet only, in order to differentiate between initiation and promotional effects of supplementation. The group fed a linseed-supplemented diet only during the promotional stage of mammary carcinogenesis had a significantly smaller ($p<0.05$) tumour volume (66.7%) than all other groups, but also an increased tumour burden and number of tumours per group compared with the group fed the supplemented diet throughout the experiment. Feeding the basal diet at the initiation stage of tumour development resulted in a greater number of tumours occurring consistently over time. However, linseed supplementation at initiation and throughout the experimental period tended to reduce the number of tumours per tumour-bearing rat [Serraino 1992b].

After administration of a single dose of 5 mg of 7,12-dimethyl benz[a]anthracene, 5 groups of female rats (n=19-21) received either a basal diet or a diet supplemented with SDG (2200 nmol/day), 1.82% of linseed oil or 2.5 or 5% of linseed. After 7 weeks of treatment, the volume of established tumours was over 50% smaller in all treatment groups ($p<0.08$, $p<0.04$, $p<0.04$, $p<0.04$ respectively) whereas there was no change in the basal diet group. The number and volume of new tumours were lowest in the SDG ($p<0.02$) and 2.5% linseed ($p<0.07$) groups. Combined established and new tumour volumes were smaller in the SDG, 2.5 and 5% linseed groups ($p<0.02$) than in the linseed oil and basal diet groups [Thompson 1996].

White Leghorn hens received a 10% linseed-enriched or standard diet for 1 year. The incidence and severity of ovarian cancer were determined by gross pathology and histology in the two groups. Eggs were collected and analysed to determine omega-3 fatty acid levels. A significant reduction in the number of late stage ovarian tumours was detected in the linseed-fed hens ($p<0.05$). Incidence rates of ovarian cancer were not significantly different between the two groups. Linseed-fed hens' eggs incorporated significantly more omega-3 fatty acids compared to control ($p<0.05$) [Ansenberger 2010].

In a similar study, COX-1 and COX-2 localisation, protein and mRNA expression, and PGE2 and PGE3 concentrations in ovaries were also measured. The results demonstrated a significant reduction in the number of late stage ovarian tumours in the

linseed-fed hens compared to control ($p<0.05$). In correlation with decreased ovarian cancer severity, concentrations of PGE2 and expression of COX-2 were diminished in the ovaries of linseed-fed hens. PGE3 concentrations were below the level of detection [Eilati 2013].

Expression of highly up-regulated genes involved in the embryonic process of branching morphogenesis coincides with expression of E-cadherin in the ovarian tumour epithelium. Levels of expression of these genes in tumours from animals fed with a diet containing 10% flaxseed were reduced by 40-60%. E-cadherin and miR200 were both up-regulated in tumours from control-fed hens, whereas their expression was decreased by 60-75% in tumours from linseed-fed hens. mRNA levels were increased five-fold in tumours, with no significant difference between control-fed and linseed-fed hens [Hales 2014].

Athymic nude mice were orthotopically injected with oestrogen receptor negative breast cancer cells (MDA-MB-435). After 8 weeks mice were randomised and fed either a basal diet or the basal diet supplemented with either 10% linseed, SDG, linseed oil or combined SDG and linseed oil for 6 weeks. The SDG and linseed oil levels were equivalent to the amounts in the 10% linseed. Compared to the basal diet, the tumour growth rate was significantly lower ($p<0.05$) in the linseed, linseed oil and SDG + linseed oil groups, in concordance with decreased cell proliferation and increased apoptosis. Incidence of lung metastasis was reduced (16–70%) by all treatments, significantly ($p<0.05$) in the linseed and SDG + linseed oil groups. Distant lymph node metastasis was significantly ($p<0.05$) decreased by 52% only in the linseed oil group. Although the total metastasis incidence was significantly lowered by 42% ($p<0.05$) only in the SDG + linseed oil group, all treatment groups did not differ significantly from each other [Wang 2005].

Ovariectomised mice were treated with continuous release of 17β-oestradiol by pellets implanted s.c. that provided continuous release of E2 at serum concentrations of approx. 250 pmol/L, which is in the range of physiologic levels seen in mice during the oestrous cycle. MCF-7 tumours were established and mice were fed with basal diet or basal diet supplemented with 10% ground linseed; two groups fed the basal diet received daily injections with enterodiol or enterolactone (15 mg/kg b.w.). Linseed, enterodiol and enterolactone counteracted oestradiol-induced growth and angiogenesis in solid tumours. VEGF was significantly decreased in all intervention groups compared with the basal diet alone ($p<0.001$) [Bergman Jungeström 2007].

Five groups of eight Apc^{Min} mice were fed with control, corn meal, linseed meal, corn oil or linseed oil supplemented diets. Linseed significantly decreased ($p<0.05$) tumour multiplicity and size in the small intestine and colon as compared to control or corn-treated groups. COX-1 and COX-2 expression in the colon samples from the linseed group were significantly lower ($p<0.05$) as compared to the corn group [Bommareddy 2009].

Ovariectomised athymic mice with established MCF-7 tumours were fed a basal diet or basal diet supplemented with linseed oil (40g/kg) for 8 weeks. Compared with pre-treatment, linseed oil reduced tumour size by 33% ($p< 0.05$). Furthermore, linseed oil reduced tumour cell proliferation by 38% ($p<0.05$) and increased apoptosis by 110% ($p<0.01$). It also reduced epidermal growth factor receptor-2 (79%, $p<0.05$) and epidermal growth factor receptor (57%, $p=0.057$) expression. Insulin-like growth factor-1 receptor, vascular endothelial growth factor receptor, MAPK and phosphorylated Akt were not affected. Linseed oil significantly increased ($p<0.001$) serum ALA, eicosapentaenoic acid and docosahexaenoic acid [Truan 2010].

Antihypertensive activity

Thermoase-digested linseed protein hydrolysate samples and peptide fractions were sequentially tested in spontaneously hypertensive rats. The samples produced with 3% thermoase digestion showed the highest ACE- and renin-inhibitory activities. Whereas membrane ultrafiltration resulted in significant ($p<0.05$) increases in ACE inhibition by the <1 and 1–3 kDa peptides, only a marginal improvement in renin-inhibitory activity was observed for almost all samples. The protein hydrolysate samples and peptide fractions also lowered systolic blood pressure with the largest effect occurring after oral administration (200 mg/kg b.w.) of the 1–3 kDa peptide fraction of the 2.5% protein hydrolysate and the 3–5 kDa fraction of the 3% protein hydrolysate [Nwachukwu 2014].

Anti-inflammatory activity

In a murine model of acute lung injury and inflammation, mice were fed with normal or 10% linseed-supplemented diets for at least 3 weeks prior to challenge with hyperoxia (80% oxygen), intratracheal instillation of LPS or acid aspiration. Bronchoalveolar lavage was evaluated for white blood cells, neutrophils and proteins after a 24 h postintratracheal challenge of hydrochloric acid or LPS, or after 6 days of hyperoxia. Following hyperoxia and acid aspiration, bronchoalveolar lavage neutrophils decreased in linseed-supplemented mice ($p=0.012$ and $p=0.027$ respectively). In contrast, neither lung injury nor inflammation were ameliorated by linseed following lipopolysacharide instillation. Lung MDA levels were lower in hyperoxic mice than in unchallenged mice ($p=0.0001$) and decreased with linseed treatment following acid aspiration ($p=0.011$) [Kinniry 2006].

In male rats (n=32) circular, full thickness wounds with 7 mm^2 diameter were caused to both sides of the spine. Two concentrations of linseed oil (0.75 and 1.5%) were applied to the wounds as an ointment. Tissue samples were obtained at the end of 3, 7, 14 and 21 days. Treated animals showed significant reduction of inflammatory cells during re-epithelisation ($p<0.05$). Linseed oil significantly accelerated the wound healing process ($p<0.05$) [Farahpour 2011].

The anti-apoptotic and anti-inflammatory effects of a diet containing 10% linseed were evaluated in a mouse model of lung ischaemia/reperfusion injury (IRI) involving 60 min of ischaemia followed by 180 min of reperfusion. The mice fed linseed had significantly lower levels of caspases and decreased apoptotic activity compared with mice fed without linseed ($p=0.003$). Lung homogenates and bronchoalveolar lavage fluid analysis demonstrated significantly reduced inflammatory infiltrates in mice receiving the linseed diet ($p<0.001$). Additionally, linseed treated mice showed significantly increased expression of antioxidant enzymes and decreased markers of lung injury ($p<0.001$) [Razi 2011].

Male fa/fa and lean Zucker rats were fed with a control diet, and fa/fa rats were fed with an α-linolenic-acid-rich linseed oil supplemented diet for 8 weeks. Adipose tissue and serum were collected and analysed for cytokine (TNF-α, IL-10), haptoglobin, monocyte chemoattractant protein-1 (MCP-1) and adipokine (leptin, adiponectin) levels. Splenocytes were isolated and *ex vivo* mitogen-stimulated cytokine production was measured. Fa/fa rats receiving the linseed oil supplemented diet had 17% smaller adipocytes and 5-fold lower MCP-1 levels in adipose tissue than control. Adipose tissue levels of IL-10 were 72% lower in fa/fa rats fed the oil-supplemented diet compared to baseline, and their TNF-α levels decreased by 80% (equal to levels in lean Zucker rats fed the control diet) compared to fa/fa rats receiving the control diet. There were no changes in *ex vivo* cytokine production by splenocytes between intervention

fa/fa rats and control fa/fa rats. Macrophage infiltration was not different among the groups; however, fa/fa rats receiving the oil had less T-cell infiltration than those receiving control diet [Baranowski 2012].

Photoprotective effect
Sprague-Dawley male albino rats (n=21) were exposed to UV C light for 1 h twice a day for 4 weeks. Rats were divided into three groups as control, UV C and UV C + linseed oil orally (4 mL/kg b.w.). While MDA and protein carbonyl levels of the UV C group increased compared to control, their levels decreased in the UV C + linseed oil group compared with the UV C group in skin, lens and serum. Skin glutathione level decreased significantly ($p<0.05$) in the UV C and UV C + linseed oil groups. Glutathione peroxidase and SOD activities were lower in the UV C group, but higher in the UV C + linseed oil group in skin, lens and serum. While retinal apoptosis increased in both the UV C and the UV C + linseed oil groups, it was lower in the UV C + linseed oil group [Tülüce 2012].

Antioxidant effect
Adult male Wistar rats were pre-fed with a normal PUFA-enriched diet or a diet supplemented with 15% linseed oil for 10 days followed by a single i.p. dose of cisplatin (6 mg/kg b.w.). Serum/urine parameters, enzymes of carbohydrate metabolism and oxidative stress were analysed. The alterations caused by cisplatin treatment were ameliorated in rats fed with the linseed oil supplemented diet [Naqshbandi 2012].

Pharmacological studies in humans

Effect on blood glucose levels
Viscous types of dietary fibre may cause a delay in gastric emptying as shown in two studies with 11 and 7 healthy volunteers [Jenkins 1978; Holt 1979]. In these studies and in one involving 8 non-insulin-dependent diabetic volunteers [Jenkins 1976], it was demonstrated that addition of certain types of dietary fibre to the diet significantly decreased postprandial hyperglycaemia. Thus an improvement in the control of blood-glucose concentration might be expected [Jenkins 1976].

Oestrogenic effects
Quantitative urine assays in 62 women studied 4 times during one year showed a significant positive correlation between the intake of fibre and urinary excretion of lignans and phytoestrogens and the concentration of plasma SHBG [Adlercreutz 1987].

In an open, randomised, cross-over study involving 18 women with normal cycles, the effects of ingestion of linseed powder on the menstrual cycle were investigated. Each subject consumed her usual omnivorous, low fibre (control) diet for 3 cycles and her usual diet supplemented with linseed (10 g/day) for another 3 cycles. The second and third linseed cycles were compared to the corresponding control cycles. During the 36 control cycles, 3 anovulatory cycles occurred, compared to none during the 36 linseed cycles. Compared to ovulatory control cycles, the ovulatory linseed cycles were consistently associated with longer luteal phase (LP) lengths (mean 12.6 vs. 11.4 days; $p=0.002$). There were no significant differences between linseed and control cycles in concentrations of oestradiol or oestrone during the early follicular phase, midfollicular phase or LP. Although linseed ingestion had no significant effect on LP progesterone concentrations, LP progesterone/oestradiol ratios were significantly higher during the linseed cycles. Midfollicular phase testosterone concentrations were slightly higher during the linseed cycles. Linseed ingestion had no effect on early follicular phase concentrations of DHEA-S, PRL or sex hormone-binding globulin [Phipps 1993].

Clinical studies

Effect on gastro-intestinal complaints

Laxative effect
Dietary fibre such as linseed binds with water and swells to form a demulcent gel in the intestine. As water bound to the fibre is prevented from being absorbed in the colon, the faeces are softened and the volume of bowel contents increases [Schilcher 1986a; Brunton 1990; Teuscher 2016].

A decrease in transit time and increase of stool weight by physical stimulation of intestinal peristalsis with linseed have been demonstrated in two multicentric studies (n=108 and n=114) in patients suffering from constipation [Kurth 1976; Jens 1981].

Effect on gastro-intestinal complaints
The mucilage has been reported to have a palliative effect in patients with pain associated with gastro-intestinal problems [Schilcher 1986a; Teuscher 2016].

In an open pilot study 70 patients suffering from various functional upper abdominal complaints such as sensations of pressure and repletion, loss of appetite, nausea, vomiting and heartburn were treated with an aqueous linseed mucilage preparation (1:10) at a dosage of 8 × 25 g (including a small amount of excipients) per day. All except three patients experienced improvements. After 3 days the total symptom score had significantly decreased ($p<0.01$). Each individual symptom score decreased on average, the largest reductions being observed for the sensation of pressure (41.5%) and the sensation of repletion (36.8%). In global assessments by both patients and physicians the efficacy was rated as good or very good in most cases [Grützner 1997].

Effect on blood lipid levels
In a meta-analysis, 28 published studies were assessed according to the Jadad score. Linseed at a daily dose ranging from 20.0 to 50.0 g significantly ($p=0.04$) reduced total cholesterol (TC) and LDL-C by 0.12 mmol/L and 0.15 mmol/L respectively. The cholesterol-lowering effects were more apparent in females (particularly postmenopausal women), individuals with high initial cholesterol levels and in studies with higher Jadad scores. No significant changes were found in the concentrations of HDL-C and triglycerides [Pan 2009b].

In a randomised, cross-over trial, 22 men and 7 postmenopausal women with hyperlipidaemia who followed a National Cholesterol Education Program (NCEP) Step II diet received fibre-rich muffins containing either partially defatted linseed (approx. 50 g daily) or wheat bran as a control, both corresponding to approx. 20 g of fibre daily, for 3 weeks; the treatment phases being separated by at least 2 weeks. Linseed supplementation significantly reduced TC by 4.6% ($p=0.001$), LDL-C by 7.6% ($p<0.001$), apolipoprotein B by 5.4% ($p=0.001$) and apolipoprotein A-I by 5.8% ($p=0.070$) compared to the control, but had no effect on serum lipoprotein ratios. No significant effects were observed on serum HDL-C, serum protein carbonyl content or *ex vivo* androgen and progestin activity [Jenkins 1999].

Menopausal women were randomly assigned to consume 40 g linseed/day (n=101) or wheat germ placebo (n=98) for 12 months. Linseed significantly reduced serum TC by 0.20 ± 0.51 mmol/L ($p=0.012$) and HDL-C by 0.08 ± 0.24 mmol/L ($p=0.031$) compared with wheat germ placebo, whereas the reduction of LDL cholesterol by 0.13 mmol/L was borderline significant ($p=0.086$) [Dodin 2005].

Mild to moderately hypercholesterolaemic (≥5.1 to ≥9.8 mmol/L)

postmenopausal women (n=55) were randomly assigned to control, linseed or linseed + additional oat bran fibre groups. The participants in the linseed and linseed + fibre treatment groups consumed in total 29 g linseed per day. There was a significant decrease of approximately 7% ($p<0.05$) in the mean TC level after 3 months of consumption of linseed or linseed + fibre. No change in TC was observed for women in the control group. In both linseed groups LDL-C was significantly reduced by approximately 10% ($p<0.05$). The levels of HDL-C and triglycerides remained unaltered [Patade 2008].

In an open, randomised clinical trial, 30 haemodialysis patients with dyslipidaemia (triglyceride >200 mg/dL and/or HDL-cholesterol <40 mg/dL) received either 40 g/day ground linseed for 8 weeks or their usual diet without linseed. Serum concentrations of triglyceride ($p<0.01$), TC ($p<0.01$), LDL-C ($p<0.01$) and CRP ($p< 0.05$) decreased significantly in the linseed group at the end of week 8 compared with baseline, whereas serum HDL-C showed a significant increase ($p<0.01$) [Khalatbari 2013].

In a double-blind, randomised, placebo-controlled trial, the effects of a diet for 12 months with foods that contained either 30 g of milled linseed (n=58) or 30 g of whole wheat were examined in patients (n=52) with peripheral artery disease. Plasma lipids were measured at 0, 1, 6 and 12 months. Consuming linseed resulted in a 15% reduction of circulating LDL-C after 1 month ($p=0.05$). The concentration in the linseed group (2.1 ±0.10 mmol/L) tended to be less than in the placebo group (2.5 ±0.2 mmol/L) at 6 months ($p=0.12$), but not at 12 months ($p=0.33$). TC also tended to be lower in the linseed group than in the placebo group after one month (11 %, $p=0.05$) and 6 months (11 %, $p=0.07$), but not at 12 months ($p=0.24$) [Edel 2015].

An 8-week, randomised, double-blind, placebo-controlled study was conducted in 55 hypercholesterolaemic subjects, receiving placebo or the linseed lignan SDG at 300 or 600 mg/day. Significant ($p<0.05$ to <0.001) effects of SDG treatment were found for the decrease of TC, LDL-C and glucose concentrations, when compared to placebo as well as to baseline. At weeks 6 and 8 in the 600 mg SDG group, the decreases of TC and LDL-C concentrations were in the range from 22 to 24.9% respectively (all $p<0.005$ compared with placebo). For the 300 mg SDG group, the only significant differences from baseline were observed for decreases of TC and LDL-C. A substantial lowering of the concentrations of fasting plasma glucose was also noted in the 600 mg SDG group at weeks 6 and 8, especially in the subjects with baseline glucose concentrations ≥5.83 mmol/L (lowered by 25.6 and 25%; $p=0.015$ and $p=0.012$ respectively, compared with placebo). Plasma concentrations of SECO, enterodiol and enterolactone were all significantly raised in the groups supplemented with SDG. The observed cholesterol-lowering effects were correlated with the plasma concentrations of SECO and ED ($r = 0.128$-0.302; $p<0.05$ to <0.001) [Zhang 2008].

In a double-blind, randomised, placebo-controlled study, 30 hypercholesterolaemic men with TC levels of 4.65 to 6.21 mmol/L received SDG (20 or 100 mg/day) or placebo for 12 weeks. Subjects receiving 100 mg of SDG exhibited a significant ($p<0.05$) reduction in the ratio of LDL/HDL-cholesterol at week 12 compared to both baseline and placebo [Fukumitsu 2010].

In a 6-week, randomised, double-blind, placebo-controlled study, 37 subjects (13 men and 24 women; age: 54 ± 7 years; BMI: 29.7 ± 1 kg/m^2) consumed nutrition bars containing 3.0 g of α-linolenic acid and different amount of lignans (0.15 g vs. 0.41 g). The high-lignan bar decreased TC by 12% ($p=0.044$), LDL-C by 15% ($p=0.022$), and oxidised LDL by 25% ($p=0.035$). The lower lignan concentration tended to increase oxidised LDL by 13% ($p=0.051$). The difference between the effects of high-lignan vs. low lignan on oxidised LDL was significant ($p=0.004$) [Almario 2013].

Antihypertensive activity

In a meta-analysis of 15 trials (comprising 19 treatment arms) with 1302 participants following supplementation with various linseed products, significant reductions in both systolic blood pressure (SBP) (weighed mean difference: -2.85mmHg, $p=0.027$) and diastolic blood pressure (DBP) (weighed mean difference: -2.39mmHg, $p=0.001$) were shown. Stratification according to duration showed a greater effect on both SBP and DBP in the subset of trials with ≥12 weeks of duration (weighed mean difference: -3.10mmHg, $p=0.072$ and -2.62mmHg, $p=0.003$ respectively) vs. the subset treated for <12 weeks (weighed mean difference: -1.60mmHg, $p=0.413$, and -1.74mmHg, $p=0.202$, respectively). Reduction of SBP was significant with linseed powder (weighed mean difference: -1.81mmHg, $p<0.001$) but not oil (weighed mean difference: -4.62mmHg, $p=0.211$) or lignan extract (weighed mean difference: 0.28mmHg, $p=0.885$). However, DBP was significantly reduced with powder and oil preparations (weighed mean difference: -1.28mmHg, $p=0.031$, and -4.10mmHg, $p=0.003$, respectively), but not with lignan extract (weighed mean difference: -1.78 mmHg, $p=0.162$) [Ursoniu 2015].

In another meta-analysis including 11 studies (14 trials) involving 1004 participants, similar outcomes were found. Results indicated that linseed supplementation reduced SBP (-1.77mmHg; $p=0.04$) and DBP (-1.58mmHg; $p=0.003$). The results were not influenced by categorisation of participants with a higher baseline blood pressure (≥130mmHg). A significant improvement in DBP was observed in the subgroup consuming whole linseed (-1.93mmHg; $p<0.05$) and in the subgroup of studies with a duration of at least 12 weeks (-2.17mmHg; $p<0.05$) [Khalesi 2015].

In a parallel, single-blind trial, 75 overweight adolescents received 28 g/d of brown linseed, golden linseed or placebo for 11 weeks. The groups consuming brown and golden linseed showed a significant ($p<0.05$) reduction in diastolic blood pressure [Machado 2015].

In a prospective, randomised, double-blind, placebo-controlled trial, 110 patients with peripheral artery disease received 30 g of milled linseed or placebo daily for 6 months. SBP was approx. 10mmHg lower (–6.5% reduction; $p=0.04$), and DBP was approx. 7mmHg lower (–9.8% reduction; $p=0.004$), in the linseed group compared with placebo after 6 months. Patients with a SBP ≥140mmHg at baseline showed a significant reduction of 15mmHg in SBP ($p=0.04$) and 7mmHg in DBP ($p=0.004$) after intake of linseed. The antihypertensive effect was achieved selectively in hypertensive patients [Rodriguez-Leyva 2013].

Anti-inflammatory activity

In a randomised, double-blind, placebo-controlled crossover study, healthy postmenopausal women (n=22) consumed 500 mg/d of SDG or placebo daily for 6 weeks, separated by a 6-week washout period. A significant difference of approximately 15% ($p=0.028$) was observed for CRP concentration between SDG intervention period and placebo. Median CRP concentrations were 0.88 mg/L at baseline and 0.92 mg/L after SDG intervention period compared with 0.80 mg/L at baseline and 1.10 mg/L after placebo. No significant differences in IL-6, TNF-α, soluble intracellular adhesion molecule-1, soluble vascular cell adhesion molecule-1 and monocyte chemoattractant protein-1

were found between the SDG intervention and placebo periods [Hallund 2008].

Diabetic patients (26 men and 44 post-menopausal women) with mild hypercholesterolaemia completed a randomised, double-blind, placebo-controlled, cross-over trial receiving linseed-derived lignan (360 mg/day) or placebo for 12 weeks, separated by an 8-week wash-out period. Baseline to follow-up concentrations of CRP increased significantly within the placebo group (1.42 ± 0.19 vs. 1.96 ± 0.22 mg/L, p<0.001), but were comparatively unchanged in the lignan-supplemented group (1.67 ± 0.19 vs. 1.90 ± 0.26 mg/L, p=0.94); a significant mean difference was observed between treatments of -0.45 mg/L, p=0.021. This effect was confined to women (p=0.016). No between-treatment differences were found with regard to IL-6 or RBP4; although IL-6 concentrations increased significantly from baseline to follow-up in both groups (p=0.004 and p<0.001 following lignan and placebo treatments respectively) [Pan 2009a].

Patients with chronic renal failure undergoing haemodialysis therapy (n=160) were included in a randomised, double-blind, multicentre, placebo-controlled trial. The patients received linseed oil (1 g twice a day) or placebo (mineral oil, 1 g twice a day) for a period of 120 days. Inflammation was observed in 89 patients (61%) at the beginning of the study. There was a correlation between CRP and the body mass index (R_s=0.22; p=0.022) and HDL-cholesterol (R_s=–0.23; p=0.032). The CRP levels decreased significantly in the verum group compared to placebo (p<0.001). In the verum group inflammation disappeared in 33.3% of the patients, but only in 16.9% of the placebo group (p=0.04) [Lemos 2012].

Effect on blood glucose levels
In an 8-week, randomised, double-blind, placebo-controlled study, 55 hypercholesterolaemic subjects received either placebo, or SDG at 300 or 600 mg/day, in order to determine the effect on fasting glucose levels. A significant decrease in fasting plasma glucose concentrations was found in the 600 mg SDG group at weeks 6 and 8 compared with either placebo (p=0.019) or baseline. This decrease was greater in subjects with baseline glucose levels ≥5.8 mmol/L. At weeks 6 and 8 plasma glucose levels had decreased by 25.6% and 25.0% in the 600 mg SDG group compared with placebo (p=0.022 and p=0.021 respectively) and compared with baseline (p=0.003 and p=0.005 respectively) [Zhang 2008].

In a randomised, double-blind, placebo-controlled, cross-over trial, 73 type 2 diabetic patients with mild hypercholesterolaemia received SDG (360 mg per day) or placebo for 12 weeks, separated by an 8-week wash-out period. Of the participants, 68 completed the study. SDG significantly improved glycaemic control as measured by HbA1c (-0.10 ±0.65% vs. 0.09 ±0.52%, p=0.001) compared to placebo. However, no significant changes were observed on fasting glucose and insulin concentrations and resistance [Pan 2007].

In a randomised, cross-over study, overweight or obese men and postmenopausal women (n=25) with pre-diabetes consumed 0, 13 or 26 g ground linseed for 12 weeks. A significant decrease (p=0.036) in plasma glucose was shown for the 13 g treatment group (-2.10 ±1.66 mg/L) as compared to control (+9.22 ±4.44 mg/L). Insulin decreased in the 13 g group (-2.12 ±1.00 mU/L), but not in the 26 g (+0.67 ±0.84 mU/L) (p=0.021) and control (+1.20 ±1.16 mU/L) (p=0.013) groups [Hutchins 2013].

A total of 58 obese postmenopausal women were randomised to a single-blinded, parallel-group intervention with a daily intake of linseed mucilage (10 g) or placebo for 6 weeks. The intake of linseed mucilage led to a reduction in serum C-peptide and insulin release during an oral glucose tolerance test (p<0.05), and improved insulin sensitivity measured by the Matsuda index (p<0.05) [Brahe 2015].

Anti-tumour activity
In a systematic review including 2 randomised controlled trials, 2 uncontrolled trials, one biomarker study and 5 observational studies, linseed (25 g/day) increased the tumour apoptotic index (p<0.05) and decreased HER2 expression (p<0.05) and cell proliferation (Ki-67 index; nonsignificant) among newly diagnosed breast cancer patients when compared with placebo. The uncontrolled and biomarker studies suggested beneficial effects on cell proliferation, atypical cytomorphology and mammographic density, as well as a potential anti-angiogenic activity at doses of 25 g ground linseed or 50 mg SDG daily. Observational data suggest associations between linseed and decreased risk of primary breast cancer (adjusted odds ratio [AOR]=0.82; 95% CI=0.69-0.97), better mental health (AOR=1.76; 95% CI=1.05-2.94), and lower mortality (multivariate hazard ratio = 0.69; 95% CI=0.50-0.95) among breast cancer patients [Flower 2014].

In a multi-centre, randomised, controlled trial, 161 prostate cancer patients were assigned at least 21 days before prostatectomy to one of the following four groups: control (usual diet); linseed-supplemented diet (30 g/day); low-fat diet (<20% total energy); or linseed-supplemented, low-fat diet. Proliferation rates were significantly lower (p<0.002) among men assigned to the linseed groups. Median Ki-67 positive cells/total nuclei ratios (x100) were 1.66 (linseed-supplemented diet) and 1.50 (linseed-supplemented, low-fat diet) vs. 3.23 (control) and 2.56 (low-fat diet). No differences were observed between the groups with regard to side effects, apoptosis and most of the serological endpoints [Demark-Wahnefried 2008].

Pharmacokinetic properties

Pharmacokinetics in humans

Absorption
SDG undergoes metabolism principally to SECO, enterodiol and enterolactone in the human gastrointestinal tract. In the polarised Caco-2 cell system, lignans (100 µM) were added to acceptor or donor compartments and samples were taken at 2 h. Apical-to-basal permeability coefficients for SECO, enterodiol and enterolactone were 8.0 ± 0.4, 7.7 ± 0.2 and 13.7 ± 0.2 (x10-6) cm/s respectively, whereas efflux ratios were 0.8-1.2, consistent with passive diffusion. Permeation of SDG was not detected [Mukker 2014].

Distribution
In digested whole linseed, the bioaccessibility values (free lignan)/(total lignan) of SECO, enterodiol and enterolactone were 0.75%, 1.56% and 1.23% respectively. Conversely, in digested linseed flour, the bioaccessibility values of SDG, enterodiol and enterolactone were 2.06%, 2.72% and 1.04% respectively. The anaerobic count and short-chain fatty acids indicate that bacteria survival and carbohydrate fermentation occurred [Fuentealba 2014].

Metabolism
Three interrelated pharmacokinetic studies were performed in healthy postmenopausal women after oral intake of 25 to 172 mg of SDG. Steady-state lignan concentrations were obtained after daily intake for one week. Blood and urine samples were collected at timed intervals, and SECO, enterodiol and enterolactone concentrations measured. SDG was efficiently hydrolysed and converted to SECO. Serum concentrations increased after oral intake with t_{max} of 5-7 h and $t_{1/2}$ of 4.8 h.

Maximum serum concentrations of enterodiol and enterolactone were established after 12-24 h and 24-36 h respectively, and $t_{1/2}$ was 9.4 h and 13.2 h respectively. A linear dose-response-relationship was observed and SECO bioavailability correlated (r^2=0.835) with cumulative lignan excretion [Setchell 2014].

For metabolism studies, lignans (100 µM) were incubated with Caco-2 cells for a maximum of 48 h. Cell lysates and media were treated with β-glucuronidase/sulfatase, and lignan concentrations were determined. The extent of conjugation after 48 h was <3%, ~95%, ~90%, and >99% for SDG, SECO, enterodiol, and enterolactone respectively [Mukker 2014].

Elimination
The effects of linseed powder on urinary lignan and isoflavonoid concentrations were investigated in 18 premenopausal women in a randomised crossover study. Each woman consumed her usual omnivorous diet, except avoiding foods containing linseed or soy (high isoflavone content) for 3 menstrual cycles and her usual diet supplemented with linseed (10 g/day) for another 3 cycles, or vice versa. Three-day urine samples from follicular and luteal phases were analysed. Excretion of the two major mammalian lignans, enterodiol and enterolactone, increased with linseed supplementation from 1.09 ±1.08 and 3.16 ±1.47 to 19.48 ±1.10 and 27.79 ±1.50 µmol/day respectively (p<0.0002). Enterodiol and enterolactone excretion in response to linseed varied widely among the subjects (3- to 285-fold increase). There were no differences in excretion of isoflavonoids or the lignan matairesinol with linseed. Excretion was not altered by phase of the menstrual cycle or duration of linseed consumption [Lampe 1994].

As a sub-study of the above study, involving 13 women from the original 18 and the same dietary design, faeces were collected on days 7-11 of the last menstrual cycle in each diet period. Excretion of lignans (nmol/day) increased significantly with linseed intake, from 80.0 ± 80.0 to 2560 ± 3100 for enterodiol (p<0.01), from 640 ± 480 to 10,300 ± 7580 for enterolactone (p<0.01), and from 7.33 ±10.0 to 11.9 ±8.06 nmol/day for matairesinol (p<0.05). There were no differences in faecal excretion of isoflavonoids [Kurzer 1995].

In a randomised, cross-over study, 9 healthy young women supplemented their diets with 5, 15 or 25 g of raw or 25 g of processed (as muffin or bread) linseed for 7 days during the follicular phase of their menstrual cycles. Urine samples (24-hours) were collected at baseline and on the final day of supplementation. As an adjunct to the 25 g raw linseed arm, they consumed 25 g for an additional day. Blood and urine samples were collected at specific intervals and analysed for enterolactone and enterodiol. A dose-dependent increase in urinary lignan excretion in response to linseed was observed (r=0.72, p<0.001), and processing did not affect the quantity of lignan excretion. Plasma lignan concentrations were significantly greater than baseline (p<0.001) by 9 hours after linseed ingestion (29.35 and 51.75 nmol/L respectively). The total plasma AUC was higher on the 8th than on the 1st day (1840 and 1027 nmol·h/L, respectively) [Nesbitt 1999].

Preclinical safety data

Acute toxicity
No toxic effects of linseed were observed in a brine shrimp lethality bioassay [Mahmoud 1992].

Mutagenicity and carcinogenicity
Linseed did not show any mutagenic activity in the Ames test using Salmonella typhimurium strains TA 98 and TA 102 [Mahmoud 1992].

Reproductive toxicity
Linseed and linseed meal exerted reproductive changes in the offspring of rats, such as shortening of the anogenital distance and lengthening of oestrous cycles. However, maternal consumption of linseed or SDG during suckling did not affect reproductive indices in male or female offspring [Adolphe 2010].

There were no significant effects of exposing male or female offspring to SDG during suckling on any measured reproductive indices [Imran 2015].

Clinical safety data
No drug-related adverse effects were observed from treatment of 70 patients with functional upper abdominal complaints with an aqueous linseed mucilage preparation (1:10) at a dosage of 8 × 25 g (including a small amount of excipients) daily for 3 days [Grützner 1997].

Natural, heated and extruded fresh linseed were tested using prick-in-prick tests (PIP), SDS PAGE, immunoblots, immunoblot inhibition and Fourier Transform Infrared spectroscopy. PIP tests to linseed were positive in 5.8% of the 1,317 patients. Of the 77 PIP-positive patients, 73 were atopic. There was cross-reactivity with peanut, soybean, rapeseed, lupine and wheat as well as with rape pollen [Fremont 2010].

Participants aged 49-87 years were randomised in a double-blind trial to receive linseed lignan (543 mg/day) or placebo while completing a 6-month walking program. Participants (n=94) who completed the study were stratified by age (<65 years versus >65 years) and treatment category to determine whether older adults were more susceptible to adverse effects. After 6 months of treatment, average plasma glucose level (5.4 ± 0.6 mmol/L), SBP (127 ± 14mmHg), and DBP (80 ± 9mmHg) were within normal clinical range. Controlling for sex and body mass index covariates resulted in no differences between plasma glucose or blood pressure measurements between treatment or age groups (p>0.05). No incidents of hypoglycaemia or hypotension were observed during treatment [Billinsky 2013].

A case of anaphylaxis after intake of linseed was reported. Skin prick tests with linseed yielded positive results [Alonso 1996; Alvarez-Perea 2013].

Investigations in healthy women suggest that linseed may have an oestrogenic effect [Phipps 1993]. There is a lack of sufficient data about the safety of linseed in pregnancy [Basch 2007]. In accordance with general medical practice, the product should not be used during pregnancy without medical advice.

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

MALVAE FLOS

Mallow Flower

2016

DEFINITION

Mallow flower consists of the whole or fragmented dried flowers of *Malva sylvestris* L. or its cultivated varieties.

The material complies with the monograph of the European Pharmacopoeia [Malvae flos].

CONSTITUENTS

The main characteristic constituents are:

- Mucilage polysaccharides (6% to more than 10%; mean molecular weight 83,000 D) composed of neutral and acidic monosaccharide residues including galactose, rhamnose, arabinose, glucose and xylose as well as galacturonic acid and glucuronic acid [Classen 1998; Franz 1966; Rosik 1984; Karawya 1971; Blaschek 2014; Paris, Moyse 1967].

- Anthocyanins (6-7%), mainly malvidin 3,5-diglucoside, malvidin 3-glucoside, malvidin 3-(6''-malonylglucoside)-5-glucoside and delphinidin 3-glucoside with traces of petunidin and cyanidin glycosides [Blaschek 2014; Pourrat 1990; Takeda 1989].

- Flavonols such as quercetin-3-*O*-rutinoside (1.5%) and kaempferol-3-*O*-rutinoside (0.084%) [Barros 2012].

Other constituents include scopoletin [Tosi 1995], ursolic acid, phytosterols [Karawya 1979] and total tocopherol (0.017%) [Barros 2010].

CLINICAL PARTICULARS

Therapeutic indications
Dry cough; irritation of the oral, pharyngeal or gastric mucosa [Blaschek 2014; Nosal'ova 1994; Braun 1987].

Posology and method of administration

Dosage

Internal use
Adult dose: 1.5-2 g of the drug as an aqueous cold macerate or hot infusion, repeated if required up to a daily dose equivalent to 5 g of the drug [Blaschek 2014; Saller 1995].

External use
As a gargle, a 5% decoction [Van Hellemont 1986].

Method of administration
For oral administration or local application.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contra-indications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported. However, mucilages can reduce the absorption of other drugs taken simultaneously [Consolini 2010].

E/S/C/O/P MONOGRAPHS

Pregnancy and lactation
No human data available. In accordance with general medical practice, the product should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None known.

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties
The mucilage from mallow flower covers the epithelium, especially of the mouth and pharynx, affording protection from local irritations [Blaschek 2014; Braun 1987; Saller 1995].

In vitro experiments

Adhesion to buccal epithelium
A polysaccharide fraction (> 95% carbohydrate content) from mallow flower exhibited relatively weak adhesion to isolated porcine buccal membrane in comparison with the stronger bioadhesive effects of similarly-prepared polysaccharide fractions from marshmallow root or calendula flower [Schmidgall 2000].

Antioxidant activity
A methanolic extract showed antioxidant activity in a variety of tests: DPPH radical-scavenging activity, reducing power, inhibition of β-carotene bleaching and inhibition of lipid peroxidation [Barros 2010].

Mallow flower demonstrated dose-dependent increases in radical scavenging activity and inhibition of lipid peroxidation. The highest rate of free radical scavenging (43.5%) and the strongest inhibition of lipid peroxidation (18.8%) were obtained at a concentration of 0.20 mg/mL anthocyanins [Wang 2005].

Antibacterial and antifungal activity
A methanolic extract (not further specified) showed antibacterial activity against *Erwinia carotovora*, *Staphylococcus aureus*, *Streptococcus agalactiae* and *Enterococcus faecalis* with MIC values of 128, 192, 200 and 256 µg/mL, respectively. The extract showed a modest antifungal activity against *Candida kefyr* and *C. albicans* with an MIC range of 640 to 800 µg/mL [Razavi 2011].

In vivo experiments

Antitussive effects
The mucilage isolated from mallow flowers (*Malva sylvestris* ssp. *mauritiana*), and the acidic polysaccharide fraction from it (consisting of a rhamnogalacturonan), were administered orally to non-anaesthetized cats at 50 mg/kg b.w., in order to examine their antitussive effects. A surgically-implanted tracheal cannula served for mechanical stimulation of the airways as well as recording the side tracheal pressure on an electromanometer. Mucous membranes in the laryngopharyngeal and tracheobronchial areas were stimulated five times in succession with a nylon fibre and the effects were monitored 0.5, 1, 2 and 5 hours after administration. Both the mucilage and the rhamnogalacturonan fraction markedly reduced the number of cough efforts and the intensity of cough attacks (in both inspiration and expiration). The mucilage reduced cough frequency mainly from the laryngopharyngeal area, while the rhamnogalacturonan fraction was effective in both areas. Only the rhamnogalacturonan fraction influenced the intensity of maximum cough efforts. The effect of the mucilage and the rhamnogalacturonan fraction in suppressing the number of cough efforts was compared to that of the non-narcotic antitussive drugs prenoxdiazine (30 mg/kg) and dropropizine (100 mg/kg) and the narcotic drug codeine (10 mg/kg, as phosphate). Both herbal substances had a cough-suppressing effect higher than that of prenoxdiazine or dropropizine but lower than that of codeine [Nosal'ova 1994].

Effects on plasma lipids and free radicals
Albino rats fed a lipid rich diet received anthocyanins from mallow flower at 0.03, 0.04 and 0.05 g daily for 14 days. Plasma total cholesterol decreased by 19.7% at an anthocyanin dose of 0.04 g daily and triglycerides by 34.4% at an anthocyanin dose of 0.05 g daily [Wang 2005].

Other effects
A dry 95%-ethanolic extract administered i.p. at 50 mg/kg b.w. increased the survival rate of mice inoculated with *Escherichia coli*. The effect was attributed to stimulation of phagocytic activity of the reticulo-endothelial system [Delaveau 1980].

Pharmacokinetic properties
No data available.

Preclinical safety data
No data available.

Clinical safety data
No data available.

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

MARRUBII HERBA

2013

White horehound

DEFINITION

White horehound consists of the dried, entire or fragmented, flowering aerial parts of *Marrubium vulgare* L. It contains not less than 0.7 per cent of marrubiin ($C_{20}H_{28}O_4$; M_r 332.4) with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [White horehound].

CONSTITUENTS

The characteristic constituents are the labdane-type diterpenes marrubiin (0.12 to 1.0%) and marrubenol, metabolically derived from their precursors premarrubiin (0.13%) and premarrubenol during the growth period, as well as peregrinol or vulgarol; up to 7% tannins; up to 0.1% phenylethanoid esters, including acteoside, ballotetroside, forsythoside B, marruboside and arenarioside; essential oil (0.05 to 0.06%) consisting mainly of phenylpropanoids, mono- and sesquiterpenes; the hydroxycinnamic acids chlorogenic, caffeic, caffeoyl-L-malic acid and 1-caffeoylquinic acid; flavon- and flavonol glycosides, lactoylflavones; the methoxylated flavone ladanein; amines including choline (0.2%) and betonicine (0.3%) [Nawwar 1989; Sahpaz 2002a; Sahpaz 2002b; Martin-Nizard 2003; Belhattab 2006; Knöss 2006; Seitz 2007; Morteza-Semnani 2008; Blaschek 2009; Ahmed 2010; Alkhatib 2010; Zawislak 2011].

CLINICAL PARTICULARS

Therapeutic indications

Loss of appetite; dyspeptic complaints such as bloating and flatulence [Jänicke 2003; Schilcher 2007; Seitz 2007; Blaschek 2009].
Catarrh of the upper respiratory tract [Bradley 1992; Teuscher 2004; Schilcher 2007; Seitz 2007; Blaschek 2009].

Efficacy in these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adults:
4.5 g of the drug daily, or 1 to 2 g as an infusion three times daily [Bradley 1992; Jänicke 2003; Teuscher 2004; Barnes 2007; Schilcher 2007; Seitz 2007; Blaschek 2009].

Fluid extract (1:1, 20% ethanol): 1 to 4 ml three times daily [Bradley 1992; Jänicke 2003; Barnes 2007; Seitz 2007].

Tincture (1:5; 25% ethanol): 3 to 6 ml daily [Bradley 1992].

Pressed juice: 2 to 6 tablespoons daily [Jänicke 2003; Schilcher 2007; Seitz 2007; Blaschek 2009].

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.

Special warnings and special precautions for use
None required.

E/S/C/O/P MONOGRAPHS

Interaction with other medicaments and other forms of interaction
There are reports from a clinical trial with diabetic patients taking glibenclamide that consumption of aqueous white horehound extract was linked with minor symptoms of nausea, oral dryness or salivation, and dizziness. [Herrera-Arellano 2004].

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
See Interactions above.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro studies

Antioxidant activity
Aqueous, and methanolic extracts and the essential oil of white horehound have been shown to have free radical scavenging and antioxidant activities in various assays, including on ABTS- or DPPH-radicals, determination of ferric reducing/antioxidant power (FRAP) and the inhibition of linoleic acid peroxidation. In some of the studies the effects were attributed to the polyphenol content of the drug [VanderJagt 2002; Berrougui 2006; Katalinic 2006; Matkowski 2006; Wojdylo 2007; Dall´Acqua 2008, Kadri 2011; Pukalskas 2012.].

A 40%-methanolic dry extract (DER 25:1) inhibited the formation of conjugated dienes (CD) in a dose-dependent manner after incubation of human-LDL with $CuSO_4$. The lag phase before CD formation was significantly increased ($p=0.014$) and the maximum rate of oxidation decreased significantly ($p= 0.004$). The degradation of α-tocopherol and the electrophoretic mobility of LDL (both induced by oxidation) were attenuated. HDL-mediated cholesterol efflux from THP-1 macrophages was potentiated in a dose-dependent manner from 50 µg/ml ($p<0.05$) to 100 µg/ml ($p<0.01$) [Berrougui 2006].

Acteoside, forsythoside B, arenarioside, ballotetroside and caffeoyl-malic acid isolated from white horehound inhibited copper-initiated LDL oxidation with ED_{50} values of 0.46, 0.68, 0.64, 1.82 and 2.07 µM, respectively. There were ED_{50} values of 0.39, 0.45, 0.50, 0.72 and 1.04 µM for the inhibition of oxidation induced by 2,2´-azobis(2-aminopropane)dihydrochloride. Extra- and intracellular peroxidation in endothelial cells after incubation with minimally oxidized LDL was measured by the accumulation of thiobarbituric acid reactive substances (TBARS). At a concentration of 10 µM each compound significantly decreased the accumulation of TBARS ($p<0.001$) [Martin-Nizard 2003].

Endothelin-1 secretion in bovine aortic endothelial cells was shown to be significantly increased by treatment with LDL ($p<0.01$) and copper-oxidised LDL ($p<0.001$). Acteoside, forsythoside B, arenarioside and ballotetroside previously isolated from white horehound completely eliminated this effect. The increase in endothelin-1 gene expression after treatment with copper oxidised LDL was also reversed by these compounds ($p<0.05$) [Martin-Nizard 2004].

Vasorelaxant effects
An aqueous extract of white horehound (DER approx 6:1) given to spontaneously hypertensive rats at an oral dose of 80 mg/kg b.w. for five days, reduced KCl-induced contractions in subsequently isolated aorta by 19% ($p<0.05$). Noradrenaline-induced contractions were also decreased.Preincubation of aortic rings with the extract resulted in a dose-dependent inhibition ofKCl-induced contractions. Maximum effects were reached with 0.7 mg/ml and led to an 87% decrease in contraction of aortic rings of spontaneously hypertensive rats (EC50 0.14 mg/ml) and a 73% decrease in those of normotensive rats (EC50 0.19 mg/ml) ($p<0.05$). Calcium-induced contractions in KCl-depolarized aortic rings were markedly decreased by the extract. Contractions induced by noradrenaline were inhibited by 73% and 37% respectively, in aortic rings of spontaneously hypertensive and normotensive rats. [El Bardai 2001].

The contractile tension induced by KCl in isolated rings of the aorta and the mesenteric artery of rats treated orally with an aqueous extract (80mg/kg/day for 10 weeks) was significantly lower when compared to those of untreated rats ($p<0.05$). The effect disappeared in the presence of the NO synthase inhibitor L-NOarginine. Acetylcholine-induced relaxation of the mesenteric artery following contraction induced by noradrenaline was shown to improve [El Bardai 2004].

A dose-dependent inhibition of KCl-induced contractions in isolated rat aorta was observed after preincubation with an aqueous extract of white horehound. After fractionation of the extract the effect was most pronounced in a cyclohexane fraction with 61.2% inhibition at a concentration of 16 µg/ml and 100% inhibition at a concentration of 64 µg/ml. From this fraction marrubiin and marrubenol were isolated, significantly reducing the contractions, with IC_{50} values of 24 µM and 7.7 µM respectively ($p<0.05$) [El Bardai 2003a].

In aortic rings, after removal of the endothelium, a similar relaxant effect was observed for marrubenol with an IC_{50} of 11.8 µM and maximum inhibition of KCl-induced contractions of 93.4%. Marrubenol inhibited contractions induced by noradrenaline to a lesser extent, and was ineffective in the same experiment in the presence of the Ca^{2+} channel blocker nimodipine. In fura-2 loaded aorta, both the cytosolic Ca^{2+} concentration and the contractions were decreased by marrubenol in a dose-dependent manner. The decrease of the quenching rate of the fluorescence of the fluorescent marker fura-2 in the presence of Mn^{2+} suggested that the activity of marrubenol was caused by an inhibition of Ca^{2+} influx. The study demonstrated that marrubenol decreased Ca^{2+} influx in aortic smooth muscle cells and inhibited smooth muscle contraction by blocking L-type calcium channels [El Bardai 2003b].

Other effects
A methanolic dry extract from white horehound leaf significantly suppressed cell growth in the human colon adenocarcinoma cell line HCT-116 by induction of apoptosis at a concentration of 250 µg/ml ($p<0.05$). At 100 µg/ml the extract increased the expression of the pro-apoptotic protein NAG-1 [Yamaguchi 2006].

An ethanolic extract (not further specified) exhibited moderate activity on the viability of a murine neuroblastoma cell line as assessed with resazurin-almar blue indicator dye (LC_{50} 3.64 mg/ml) [Mazzio 2009].

An ethanolic dry extract of white horehound exhibited anti-

microbial activity against *Bacillus subtilis* in the XTT colorimetric assay [Al-Bakri 2007].

A dry acetone extract (yield 6.6%) led to 67.5% inhibition of acetylcholinesterase from the electric eel and 83.5% inhibition of butyrylcholinesterase from horse serum at dosages of 50 µg/mL [Orhan 2010].

A methanolic extract exhibited antibacterial activity against *Bacillus subtilis* and *Staphylococcus aureus* (MIC 100 mg/ml) as well as *Staphylococcus epidermidis* (MIC 200 mg/ml) [Masoodi 2008].

In an immunomodulation assay an extract prepared with phosphate-buffered saline (10 g drug/100 mL) increased the proliferation of mice splenocytes ($p<0.05$) as compared with concanavalin-A. The protein fraction of this extract reduced the mitogenic effect of concanavalin-A [Daoudi 2012].

Acteoside, forsythoside B and arenarioside isolated from white horehound showed COX-2 inhibition of 63.9%, 72.5% and 67.8% respectively, at a concentration of 1 mM. The IC_{50} values were 0.69, 0.49 and 0.61 mM. The compounds did not inhibit COX-1 [Sahpaz 2002a].

In endothelial cells, acteoside, forsythoside B, arenorioside, ballotetroside and caffeoylmalic acid (10 µM) significantly decreased the cytotoxicity of minimally oxidized LDL ($p<0.001$) [Martin-Nizard 2003].

Ladanein, isolated from white horehound, showed moderate cytotoxicity against the murine leukemia cell line DA1-3b/M2$^{BCR-ABL}$ and the human leukaemia cell lines K562, K562R and 697 with IC_{50} values of 10.4, 25.1, 38.0 and 38.0 µM, respectively. It remained without effect on human acute myeloid leukaemia cells MOLM13 and on human peripheral blood mononuclear cells from healthy volunteers [Alkhatib 2010].

In vivo studies

Gastroprotective effects
A methanolic leaf extract from white horehound (not further specified) and isolated marrubiin were tested in different models of gastric ulcer. Swiss mice received a single oral dose of 25, 50 or 100 mg/kg b.w. of the extract or 25 mg/kg marrubiin. In ulcers induced by ethanol/HCl, the extract at 50 and 100 mg/kg and marrubiin significantly reduced the ulcer lesion index ($p<0.01$). A significant decrease in the total area of lesions and the percentage of lesion area was observed but only at the highest dose of the extract and marrubiin ($p< 0.01$). In indomethacin/bethanecol-induced ulcers all doses of the extract and marrubiin led to a significant reduction of the total area of lesions, the percentage of lesion area and the ulcer lesion index ($p<0.01$). The total area of lesions and the percentage of lesion area were significantly improved by 50 and 100 mg/kg of the extract and marrubiin ($p<0.05$) as compared to the positive control cimetidin. The two higher concentrations of the extract and marrubiin significantly raised gastric pH and decreased the concentration of H^+ ions ($p<0.01$). Free gastric mucus in the tissue was enhanced in all treated groups ($p<0.01$). After pre-treatment with L-NAME it was concluded that the protective effects of the extract and marrubiin were related to NO synthesis [Paula de Oliveira 2011].

Analgesic effects
Marrubiin isolated from white horehound exhibited pronounced antinociceptive effects in different mouse models [De Jesus 1999]:

- Acetic acid-induced writhing was reduced by pretreatment with marrubiin administered intraperitoneally 30 minutes before the challenge in a range of doses. The effect was significant for up to five hours ($p<0.01$ up to four hours, $p<0.05$ at five hours). Co-treatment with naloxone did not affect the activity of marrubiin. The ID_{50} was 2.2 µmol/kg; for aspirin it was 133 µmol/kg and for diclofenac 38 µmol/kg.
- In the formalin-induced pain test, first phase nociception after 5 minutes (representing neurogenic pain) and second phase effects after 15 to 30 minutes (representing inflammatory pain) were registered. Both pain phases were significantly inhibited ($p<0.05$) in a dose-dependent manner following pretreatment of the animals with marrubiin (3 to 90 µmol/kg intraperitoneally or 90 to 900 µmol/kg orally) 60 minutes before the formalin injection.
- Capsaicin-induced neurogenic nociception was inhibited by pretreatment with marrubiin at intraperitoneal doses of 3 to 90 µmol/kg (ID_{50} 28.8 µmol/kg; maximum inhibition 76 %).
- Marrubiin administered intraperitoneally at 180 µmol/kg had no effect in the hot plate test.

Anti-oedematous effects
In a model of microvascular leakage in mouse ears, marrubiin administered intraperitoneally at 1-100 mg/kg exhibited a significant dose-dependent antioedematous effect as determined by extravasated Evans blue. The ID_{50} and maximal inhibition of oedema induced by carrageenan were 13.6 mg/kg and 63% ($p<0.01$) respectively; in histamine-induced oedema 13.8 and 73.7% ($p<0.01$); and in bradykinin-induced oedema 15.8 mg/kg and 70% ($p<0.01$). Oedema after treatment with compound 4880, serotonin or dextran was reduced by up to 46.9%, 49.3% and 32% ($p<0.01$), respectively. To determine the activity in neurogenic inflammation, microvascular extravasation of Evans blue was induced with capsaicin or substance P. For these agents maximal inhibition was 28% and 27.6%. In mice sensitized to ovoalbumin, the allergic oedema after rechallenge was reduced by 67.6% for marrubiin (100 mg/kg i.p.; $p<0.01$) as compared to a 69.8% reduction by dexamethasone (0.5 mg/kg i.p.) [Stulzer 2006].

Antihypertensive effects
An aqueous extract from white horehound (DER appr. 6:1) administered at an oral daily dose of 80 mg/kg b.w. for five days, significantly lowered the systolic blood pressure in spontaneously hypertensive rats ($p<0.05$) but not in normotensive rats. Urine output, as well as the excretion of electrolytes, creatinine and urea, remained almost unchanged in hypertensive and normotensive rats [El Bardai 2001].

Oral treatment of spontaneously hypertensive rats with an aqueous white horehound extract at 80 mg/kg b.w./day for 10 weeks resulted in a significant decrease in systolic blood pressure ($p<0.05$), similar to amlodipine at 10 mg/kg b.w./day. The extract reduced aortic but not mesenteric artery weight ($p<0.05$). [El Bardai 2004].

Hypoglycaemic effects
Oral administration of 300 mg/kg b.w. of an ethanolic extract of white horehound (not further specified) to alloxan-induced diabetic rats led to a significant decrease of the blood glucose level ($p<0.01$) [Novaes 2001].

A methanolic extract (DER approximately 8.3:1) was administered at a daily dose of 500 mg/kg b.w. for 28 days to male Wistar rats. Treatment started 11 days after induction of diabetes with streptozotocin. Blood glucose levels were significantly reduced on treatment days 14, 21 and 28 as compared to diabetic control and baseline (all $p<0.05$), and even slightly better than in the group treated with glibenclamide. Plasma insulin, muscle

glycogen and liver glycogen were significantly increased on day 28 as compared to diabetic control ($p<0.05$). Positive effects on plasma lipid profile after treament with the extract were observed: a 24% decrease in total cholesterol, a 27% reduction in LDL cholesterol and a 27% increase of HDL cholesterol ($p<0.05$ as compared to diabetic control). The treatment improved hepatic enzyme activity and nearly normalized glutathione peroxidase, glutathione reductase, glutathione-S-transferase, reduced glutathione and malondialdehyde levels (all $p<0.05$). In an oral glucose tolerance test the effect of the extract on the total AUC was similar to glibenclamide [Elberry 2011].

Alloxan-induced diabetic Wistar rats were treated with an aqueous extract of white horehound (6 g/25 ml, containing 5.1 mg flavonoids and 14.1 mg cinnamic acid derivatives per 100 mg dry weight; DER 8.3:1). Oral doses of 100, 200 and 300 mg/kg b.w.were administered twice daily for 15 days. From day 5 a significant decrease of blood glucose was observed at all doses as compared to diabetic control ($p<0.001$). The dose-dependent decrease in glycaemia was 50.75%, 61.06% and 62.55% respectively. No significant changes in body weight were observed for the animals treated with white horehound as compared to normal control. The increase in serum glucose, total lipids, triglycerides and total cholesterol in the diabetic rats was significantly reduced by the extract ($p<0.001$) at the end of the experiment. The effects were comparable to the positive control glibenclamide (5 mg/kg b.w.) [Boudjelal 2012].

A slight but not significant hypoglycaemic effect was observed in rats pretreated with an ethanolic dry extract from white horehound leaves (not further specified) at a single oral dose of 100 mg/kg b.w. received 30 min. after a glucose load of 2g/kg [Vergara-Galicia 2012].

Hepatoprotective effects
A terpenoid isolated from white horehound, *p*-menthane-5,6-dihydroxy-3-carboxylic acid, was administered orally to male Wistar rats at a dose of 50 mg/kg b.w. for 7 days after hepatotoxic challenge with CCl_4. The increase in SGOT, SGPT and ALP after intoxication was significantly reduced by the treatment ($p<0.01$, 0.01 and 0.05, respectively). The decreased level in total proteins was significantly increased ($p<0.05$). A recovery of histopathological changes to almost normal architecture of the hepatocytes after treatment with the compound was observed [Ahmed 2010].

Pharmacokinetic properties
No data available.

Preclinical safety data

Acute toxicity
After oral treatment of female rats with 2 g/kg b.w. of a methanolic extract from white horehound no signs of toxicity were observed after 30 minutes, during the first 4 hours after administration and over a follow-up period of 14 days [Paula de Oliveira 2011].

Repeated dose toxicity
Rats treated orally with an aqueous extract of white horehound at a dose of 80 mg/kg/day over a period of 10 weeks did not show any sign of adverse effects [El Bardai 2004].

Male Wistar rats receiving oral doses of 100, 250, 500 and 1000 mg/kg b.w. of a methanolic extract (DER approximately 8.3:1) for 3 weeks did not show any physical signs of toxicity during the experimental period [Elberry 2011].

Mutagenicity
A tincture of white horehound did not cause any mutagenic effect in *Salmonella typhimurium* strain TA98 in the Ames test [Schimmer 1994].

Clinical safety data

In a study with 21 diabetic patients treated with glibenclamide, an infusion of 1g white horehound three times daily was given for 21 days. Only minor side effects such as nausea, oral dryness, hypersalivation or dizziness were observed in five patients [Herrera-Arellano 2004].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

Front cover

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

MATRICARIAE FLOS

2020

Matricaria Flower

DEFINITION

Matricaria flower consists of the dried capitula of *Matricaria recutita* L.[1] [*Chamomilla recutita* (L.) Rauschert]. It contains not less than 4 mL/kg of blue essential oil and not less than 0.25% total apigenin 7-glucoside ($C_{21}H_{20}O_{10}$; M_r 432.4).

The material complies with the European Pharmacopoeia [Matricaria].

Fresh material may also be used provided that when dried it complies with the European Pharmacopoeia.

CONSTITUENTS

The main characteristic constituents are:

- the essential oil (0.3 – 1.5%): up to 50% of the sesquiterpenes (–)-α-bisabolol and its oxides A, B and C, bisabolonoxide A, up to 25% of cis- and trans-en-yne-dicycloethers (or spiroethers), spathulenol and matricin, which is converted to chamazulene on distillation (up to 15%).
- flavonoids (up to 6%), mainly flavone derivatives such as apigenin-7-glucoside and its acetyl esters (approx. 0.5%).

Other constituents include coumarins (herniarin and umbelliferone), phenolic acids and polysaccharides (up to 10%) [Ammon 1992, Zwaving 1982, Schilcher 1987, Ammon 1992, Füller 1993a, Carle 2014, Sticher 2015].

CLINICAL PARTICULARS

Therapeutic indications

Internal use

Symptomatic treatment of gastrointestinal complaints such as minor spasms, epigastric distension, flatulence and belching [Weiß 1982, Bisset 2001, Schulz 2004, Carle 2014].

External use

Minor inflammation and irritations of skin and mucosa, including the oral cavity and the gums (mouth washes), the respiratory tract (inhalations) and the anal and genital area (baths, ointments) [Weiß 1982, Glowania 1987, Saller 1990, Förster 1996, Bisset 2001].

Posology and method of administration

Dosage

Internal use

Adults:
As a tea infusion: 3 g of the drug to 150 mL of hot water, three to four times daily.
Fluid extract (1:2; 50% ethanol as preferred extraction solvent): 3 – 6 mL daily [Mills 2000, Carle 2014].
Dry extract: 50-300 mg three times daily [van Hellemont 1988, Keefe 2016, Mao 2016].
Elderly: Dose as for adults.
Children: Proportion of adult dose according to age or body weight.

External use

For compresses, rinses or gargles: 3-10% m/V infusion or 1% V/V fluid extract or 5% V/V tincture [van Hellemont 1988, Braga 2014, Carle 2010, Seyyedi 2014, Goes 2016].

[1] The correct name is *Matricaria chamomilla* L. (Kew Medicinal Plant Name Services)

E/S/C/O/P MONOGRAPHS

For baths: 5 g of the drug, or 0.8 g of alcoholic extract, per litre of water [Carle 2010].
For solid and semi-solid preparations: hydroalcoholic extracts corresponding to 3-10% m/m of the drug [Zwaving 1982, Schulz 2004].
For vapour inhalation: 10-20 mL of alcoholic extract per litre of hot water [Saller 1990].

Method of administration
For oral administration, local application and inhalation.

Duration of administration
No restriction.

Contra-indications
Sensitivity to matricaria or other members of the Compositae.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No harmful effects reported.

Effects on ability to drive and use machines
None known.

Undesirable effects
Rare cases of contact allergy have been reported in persons with known allergy to *Artemisia* species [Schilcher 1987]. Matricaria flower of the bisabolol oxide B-type can contain traces of the contact allergen anthecotulide [Schilcher 1987, Bisset 2001, Hausen 1992]. Matricaria possesses a much lower allergenic potential than other chamomile species and therefore allergic reactions to matricaria must be considered as extremely rare. Most of the described allergic reactions to matricaria were due to contamination with *Anthemis cotula* or related species, which contain high amounts of anthecotulide. However, in cases where matricaria contact allergy has been acquired, cross-reactions to other sesquiterpene lactone-containing plants are common [Hausen 1992, de Jong 1998].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Anti-inflammatory effects
Ethanolic (48% V/V) and isopropanolic (48% V/V) extracts inhibited 5-lipoxygenase, cyclooxygenase and the oxidation of arachidonic acid with IC_{50} values of 0.05 to 0.3%, while a supercritical carbon dioxide extract had an IC_{50} of 6 to 25 µg/mL for these activities. Investigation of individual constituents revealed that apigenin inhibited 5- and 12-lipoxygenase (IC_{50}: 8 and 90 µM respectively); chamazulene and (–)-α-bisabolol inhibited only 5-lipoxygenase (IC_{50}: 13 and 40 µM respectively); apigenin, cis-en-yne-spiroether and (–)-α-bisabolol inhibited cyclooxygenase (IC_{50}: 70-80 µM); only chamazulene had antioxidative activity (IC_{50}: 2 µM) [Ammon 1996].

Trans-en-yne-dicycloether inhibited the provoked degranulation of rat mast cells in concentrations above 0.1 mM [Miller 1996].

Apigenin markedly inhibited the transcriptional activation of cyclooxygenase (IC_{50}: 8.7 µM) and of nitric oxide synthase (IC_{50}: 3.1 µM) in lipopolysaccharide-activated macrophages [Liang 1999].

Matricin dose-dependently (10 – 75 µM) inhibited TNF-α and LPS-induced cell surface expression of ICAM-1 in HMEC-1 endothelial cells as well as TNF-α-induced NF-κB promotor activity (10 –100 µM) and the cytoplasm to nucleus translocation of NF-κB (10 – 75 µM). In contrast, chamazulene showed no activity [Flemming 2015].

A decoction (1:5) significantly ($p<0.0003$) and dose-dependently (5 – 20 µg/mL) inhibited luminol-amplified chemiluminescence of resting neutrophils and N-formyl methionylleucyl-phenylalanine- or phorbolmyristate acetate-stimulated neutrophils [Jabri 2016].

Antispasmodic effects
A hydroethanolic extract showed antispasmodic activity on isolated guinea pig ileum stimulated by various spasmogens. The ED_{50} (mg/mL) and the strength of activity relative to papaverine (= 1.0) were respectively 1.22 and 0.0011 with barium chloride, 1.15 and 0.0019 with histamine dihydrochloride, 2.24 and 0.00074 with bradykinin, and 2.54 and ca. 0.00062 with serotonin. Pure constituents were also investigated: with barium chloride, (–)-α-bisabolol (ED_{50}: 136 µg/mL) showed activity comparable to papaverine, while apigenin (ED_{50}: 0.8 µg/mL) was more than 3 times as active [Achterrath-Tuckermann 1980].

A methanolic (70%) dry extract demonstrated a dose-dependent (0.3 – 3 mg/mL) relaxation of spontaneous and low potassium-induced contractions in isolated rabbit jejunum. The extract (1 and 3 mg/mL) showed a Ca^{2+} antagonistic effect by shifting the concentration-response curves to the right, with a suppression of the maximum effect comparable to verapamil (0.03 and 0.1 µM) [Mehmood 2015].

Sedative effects
Apigenin competitively inhibited the binding of flunitrazepam to the central benzodiazepine receptor (Ki = 4 µM) but had no effect on muscarinic receptors, α1-adrenoreceptors or on the binding of muscimol to $GABA_A$ receptors [Viola 1995].

HPLC fractions of a methanolic extract were able to displace flunitrazepam from its receptors in rat cerebellar membranes, the ligand Ro 5-4864 from 'peripheral' benzodiazepine receptors in rat adrenal gland membranes and muscimol from GABA receptors in rat cortical membranes. The latter activity was mainly due to GABA present in the fractions [Avallone 1996].

Apigenin inhibited the binding of Ro 15-1788, a specific ligand for central benzodiazepine receptors, with an IC_{50} of 0.25 mM. Apigenin also reduced GABA-activated Cl^- currents on cultured cerebellar granule cells dose-dependently by 15 ± 3% (0.1 µM), 24 ± 2% (1 µM) and 32 ± 4% (10 µM). This effect was blocked by co-application of Ro 15-1788 [Avallone 2000].

Antimicrobial effects
Matricaria flower oil exerted a bactericidal effect against gram-positive bacteria and a fungicidal effect against *Candida albicans* at a concentration of 0.7% V/V. The oil was not active against gram-negative bacteria even in concentrations as high as 8% V/V [Aggag 1972].

An infusion, a hydroethanolic extract and pure herniarin showed

antimicrobial activity against various bacteria and fungi in the presence of near UV light [Ceska 1992, Mares 1993].

Other effects
In the MTT test, cell viability of human gingival fibroblasts treated with an ointment, containing 10% of a liquid extract, was significantly ($p<0.05$) less than that of the control [Martins 2009].

A decoction (1:5) significantly ($p<0.05$) and dose-dependently (1 – 2000 µg/mL) inhibited glucose absorption in isolated rat jejunum [Jabri 2017].

In vivo experiments

Anti-inflammatory effects
The anti-inflammatory effects of orally administered (–)-α-bisabolol have been demonstrated in carrageenan-induced rat paw oedema, adjuvant arthritis of the rat, ultraviolet-induced erythema of the guinea pig and yeast-induced fever of the rat [Jakovlev 1979].

In the carrageenan-induced rat paw oedema test the following ED_{50} values (mmol/kg) were obtained after oral administration: (–)-α-bisabolol 2.69, chamazulene 4.48, guaiazulene 4.59, matricin 2.69 and salicylamide 1.53 [Jakovlev 1983].

A dry extract prepared from infusion of 20 g of matricaria flower in 100 mL of 42% ethanol, applied topically at a dose of 750 µg per ear, inhibited croton oil-induced oedema of mouse ear by 23.4% compared to controls; benzydamine at 450 µg/ear showed a comparable inhibition of 26.6% [Tubaro 1984]. In the same test system, two isolated polysaccharides at a dose of 300 µg/ear inhibited oedema by 14% and 22% respectively [Füller 1993b].

BALB/c mice with experimentally induced atopic dermatitis (sensitized with 2,4-dinitrochlorobenzene) were treated with essential oil (3% in jojoba oil, 70 µL daily on the dorsal skin) for 4 weeks. The verum group showed a significantly ($p<0.05$) lower scratching frequency compared to controls (saline and jojoba oil vehicle). Serum IgE levels were significantly ($p<0.05$) lower at 4 weeks and histamine levels at 2 weeks [Lee 2010].

Hamsters with 5-fluorouracil-induced oral mucositis were treated twice daily for 9 days with an ointment containing 10% of a fluid extract. On day 5 of treatment, the levels of pro-inflammatory cytokines IL-1β ($p<0.05$) and TNF-α were lower than in untreated controls [Curra 2013].

Anti-ulcerogenic and wound healing effect
The development of ulcers induced in rats by indomethacin, stress or ethanol was inhibited by an orally administered extract with an ED_{50} of 1 mL per rat and by (–)-α-bisabolol with an ED_{50} of 3.4 mg/kg body weight. These substances also reduced healing times for ulcers induced in rats by chemical stress (acetic acid) or heat coagulation [Szelenyi 1979].

Rats with experimentally-induced tongue ulcers were treated twice daily with an ointment containing 10% of a fluid extract, or one of three different corticosteroid preparations, for 1, 3, 5, 7 or 14 days. Clinical and histological evaluation of the tongues revealed significantly ($p<0.05$) faster wound healing in the matricaria group when compared to both control (no treatment) and corticosteroid treatment (5 days versus 14 days) [Martins 2009].

Sixty minutes after oral treatment with a 37% ethanolic dry extract (5.65:1; 25-400 mg/kg b.w.), rats were given ethanol to induce gastric ulcers and sacrificed one hour later. The gastric ulcer index was calculated, MDA and GSH in whole blood and gastric tissue were measured. A dose of 200 mg/kg showed the greatest decrease in gastric lesions ($p<0.001$) while a dose of 50 mg/kg showed the strongest prevention of the increase in gastric tissue and blood MDA, and decrease in gastric tissue and blood GSH ($p<0.001$ and $p<0.01$ respectively) [Cemek 2010].

Male Wistar rats with a linear 3 cm incision on their back were treated topically with olive oil (control) or an extract (100 g comminuted flowers in 100 mL olive oil) twice daily for 20 days. Wound healing on days 5, 8 and 11 was significantly ($p<0.05$) better in the verum group. Complete wound closure was 4 days faster in the verum group than in control [Jarrahi 2010].

Rats with experimentally induced tongue ulcers were treated twice daily with 0.04 mL of an ointment (containing 10% of a fluid extract) for 3, 7 or 10 days. The animals were sacrificed and the tongues were examined with respect to the degree of inflammation, fibroblast count and wound size. Histometric analysis of re-epithelialization and percentage of collagen fibres of the lesion were also determined. After 10 days, treated animals showed significantly greater re-epithelialization and a higher percentage of collagen fibres than control ($p=0.008$ and $p=0.022$ respectively) [Duarte 2011].

Male Wistar rats were divided into 4 groups: normoglycaemic rats given verum treatment (ointment containing 10% of a liquid extract) or control (saline solution), and alloxan-induced diabetic rats given verum or control. After induction of oral ulcers by abrasion, the rats were treated twice daily for 10 days. On days 5 and 10 the ulcers were analysed by light microscopy, TUNEL assay and immunohistochemically (TNF-α). The histological score, the ulcer area reduction and the percentage of collagen deposition area were slightly better in the treated diabetic group compared to control [Oliveira 2016].

The wound healing activity of azulene has been demonstrated in studies on the thermally damaged rat tail [Deininger 1956] and of matricaria flower constituents in accelerated healing of experimental injuries [Zita 1955].

Sedative effects
A sedative effect of matricaria flower was demonstrated through prolongation of hexobarbital-induced sleep, reduction of spontaneous mobility and reduction of explorative activity in mice [Della Loggia 1981,1982].

Restriction stress-induced increases in plasma ACTH levels in normal and ovariectomized rats were decreased by administration of diazepam and inhalation of matricaria flower oil vapour. Inhaling the vapour induced greater decreases in plasma ACTH levels in ovariectomized rats than treatment with diazepam; this difference was not observed in normal rats. Furthermore, inhalation of the oil vapour induced a decrease in the plasma ACTH level that was blocked by pretreatment with flumazenil, a potent and specific benzodiazepine receptor antagonist [Yamada 1996].

Apigenin (25 and 50 mg/kg) significantly ($p<0.05$) reduced the time of latency in the onset of picrotoxin-induced (6 and 8 mg/kg) convulsions [Avallone 1996]. Apigenin also reduced locomotor activity after i.p. injection in rats (minimal effective dose: 25 mg/kg), but showed no anxiolytic, myorelaxant or anticonvulsant activity [Zanoli 2000].

Other effects
In an experimental model of polycystic ovary syndrome, virgin adult rats with oestradiol valerate-induced follicular cysts were

treated sixty days after induction with various doses (25, 50, 75 mg/kg i.p.) of a dry 70% ethanolic extract for 10 days. In the rats treated with 50 mg/kg, macroscopic and microscopic morphological examination of the ovarian and uterine tissues revealed a reduction of the cysts and an increase in the number of dominant follicles. Serum concentrations of oestradiol, LH and FSH were significantly ($p<0.05$) decreased in chamomile-treated groups compared to untreated cystic rats [Farideh 2010].

In the sister chromatid exchange assay, daunorubicin-induced damage in mice germ cells was dose-dependently inhibited by an essential oil up to 93.5% (5, 50 and 500 mg/kg b.w. p.o.) [Hernandez-Ceruleos 2010].

Male Wistar rats were fed with paraquat (5 mg/kg/day) with or without a dry 50% ethanolic extract (3.3:1; 50 mg/kg/day) for 7 days and then sacrificed. The extract significantly ($p<0.05$) reversed the paraquat-induced increases in lipid peroxidation and superoxide dismutase and the decrease in total antioxidant power in lung tissue [Ranjbar 2014].

Oral administration of a dry methanolic (70%) extract to mice at 150 and 300 mg/kg b.w. showed significant antidiarrhoeal and antisecretory effects against castor oil-induced diarrhoea and intestinal fluid accumulation ($p<0.01$ and 0.001 respectively), similar to the effects of cromakalim and loperamide. These effects were attenuated in animals pre-treated with K^+-channel antagonists glibenclamide or 4-aminopyridine [Mehmood 2015].

Male Wistar rats were pre-treated with a decoction (1:5; 25, 50 and 100 mg/kg b.w.) for 10 days and then intoxicated with an oral dose of ethanol (4 g/kg b.w.). The decoction significantly ($p<0.005$) inhibited the ethanol-induced increase of white blood cells and platelets. The pre-treatment also significantly ($p<0.005$) improved several ethanol-induced disturbances such as depletion of SOD, catalase, glutathione peroxidase (GPx) and thiol groups; increase of hydrogen peroxide, free iron and calcium levels [Jabri 2016].

Male Wistar rats were fed with a high-fat diet (HFD) with or without a decoction (1:5; 100 mg/kg b.w.) for 6 weeks. The decoction significantly ($p<0.05$) inhibited HFD-induced obesity; the increase in renal, hepatic and abdominal fat; the increase of serum triglycerides, total- and LDL-cholesterol; the increase of AST and ALT activities, and plasma urea and creatinine levels; the increase in renal and hepatic MDA levels; and the decrease of SOD, catalase, GPx, GSH and thiol groups [Jabri 2017].

Pharmacological studies in humans

Anti-inflammatory effects
In a comparative open study involving 20 healthy volunteers with chemically-induced toxic dermatitis, the smoothing effect on the skin of an ointment containing an extract was significantly ($p<0.01$) superior to that of 0.1% hydrocortisone acetate or the ointment base only [Nissen 1988].

In an open study on 12 healthy subjects, a cream containing an extract (20 mg/g) did not suppress UV-induced erythema but did reduce visual scores of skin redness in the adhesive tape stripping test ($p = 0.0625$) [Korting 1993]. In an analogous study, the cream produced 69% of the effect of a hydrocortisone-27-acetate ointment [Albring 1983].

In a randomized, double-blind study, 25 healthy volunteers with UVB light-induced erythema were treated with various matricaria flower preparations, hydrocortisone cream or the respective vehicle. Ranking the preparations according to visual assessment scores and mean values from chromametry, a cream containing a hydroalcoholic extract of matricaria flower gave the best result [Kerscher 1992].

Clinical studies

Anti-inflammatory effects
In a bilateral comparative study 161 patients with inflammatory dermatoses, who had been treated initially with 0.1% diflucortolone valerate, were treated during maintenance therapy with a cream containing 2% of an ethanolic extract (2.75:1; min. 10 mg/g essential oil and 3.5 mg/g α-bisabolol) or one of three alternatives: 0.25% hydrocortisone, 0.75% fluocortin butyl ester or 5% bufexamac. The therapeutic results with the extract were equivalent to those of hydrocortisone and superior to those of fluocortin butyl ester and bufexamac [Aertgeerts 1985].

In an open study on 98 cancer patients, an extract containing 50 mg of α-bisabolol and 150-300 mg of apigenin-7-glucoside per 100 g, applied three times daily, reduced oral mucositis caused by localized irradiation or systemic chemotherapy [Carl 1994].

In a phase III double-blind, placebo-controlled clinical trial involving 164 patients, a mouthwash containing an extract did not decrease 5-fluorouracil-induced stomatitis [Fidler 1996].

In a randomized, partially double-blind, comparison study, a cream containing 2% of an ethanolic extract (2.75:1; min. 10 mg/g essential oil and 3.5 mg/g α-bisabolol) was compared with a 0.5% hydrocortisone cream and placebo. Seventy-two patients with a medium-degree atopic eczema on both arms were allocated to one of the following groups (medication left arm/right arm): matricaria/hydrocortisone, matricaria/placebo, hydrocortisone/matricaria or placebo/matricaria. After 2 weeks of treatment the matricaria cream proved superior to the hydrocortisone cream and marginally superior to the placebo cream with respect to the symptoms pruritus, erythema and desquamation [Patzelt-Wenczler 2000].

In a dose response trial, 25 leukaemia patients (aged 20 to 30 years), with phlebitis resulting from i.v. chemotherapy treatment, were treated 3 times a day, until erythema was resolved, with compresses moistened with an infusion (5, 10, 20 or 40 g dried flowerheads in 400 mL water at 38°C; equivalent to doses of 1.25%, 2.5%, 5% and 10%; total flavonoid content: 0.02 to 0.19 mg/mL) or warm water as control. Phlebitis regression time was shortest in the 2.5% group. Regression time was significantly ($p<0.001$) less in the 1.25, 2.5 and 5% groups compared to control. A within group comparison showed a significantly shorter phlebitis regression time for the 2.5% group compared to the 1.25% ($p<0.01$) and 10% ($p<0.05$) groups [Reis 2011].

In a randomized controlled trial, the incidence and intensity of oral mucositis was assessed in 40 patients undergoing haematopoietic stem cell transplantation who received either routine care plus mouthwash containing a liquid standardised extract (10.7 mg/mL apigenin-7-glucoside) at 0.5%, 1% or 2% twice a day (until oral mucosa was re-established) or standard care alone. The mouthwash at 1% dosage significantly ($p=0.01$) reduced the incidence, intensity and duration of oral mucositis compared to control [Braga 2014].

In a randomized, triple-blind, placebo-controlled trial, 36 patients with recurrent aphthous stomatitis were treated for up to 3 weeks with 10 drops 3 times per day of a mouthwash containing either a tincture (not further specified) or placebo. The healing period (complete healing within 1 week), the number of ulcers (from day 4), as well as pain and burning sensation (from day 2) were significantly ($p<0.001$) lower in the verum group compared to placebo [Seyyedi 2014].

In a randomized, double-blind, placebo-controlled pilot study, 26 patients with severe carpal tunnel syndrome were treated with a night splint and topical application twice daily for 4 weeks with 5 drops of either matricaria oil (dried aqueous extract from 600 g flowers in 1 L sesame oil) or placebo oil. The verum group showed a significant improvement of symptomatic and functional status (p=0.019, p=0.016 respectively) compared to placebo, whereas electrodiagnostic parameters showed no significant changes between the groups [Hashempur 2015].

In a randomized, double-blind, placebo-controlled trial, 86 patients with mild and moderate carpal tunnel syndrome were treated with a wrist splint plus the same preparation or placebo (5 drops topically twice daily) for 4 weeks. Dynamometry, functionality and symptom severity score were significantly improved in the verum group compared to control (p=0.040, p=0.0001, p=0.017 respectively). Compound latency of the median nerve in the verum group was significantly (p=0.035) decreased compared to control [Hashempur 2017].

In a randomized, double-blind, placebo-controlled trial, 84 patients with knee osteoarthritis were treated topically three times daily with either the same oil preparation at a dose of 1.5 mL, a 1% diclofenac gel or placebo for 3 weeks. The oil significantly (p=0.001) reduced the use of paracetamol tablets as compared with diclofenac and placebo groups. There were no significant between group differences in pain, physical function and stiffness as determined by the WOMAC questionnaire [Shoara 2015].

In a randomized, double-blind, placebo-controlled trial, 30 patients with fixed orthodontic appliances suffering from gingival inflammation and plaque formation were treated with 15 ml of a mouthwash containing either 1% of an extract (not further specified), 0.12% chlorhexidine or placebo, twice daily for 15 days. The visible plaque index and gingival bleeding index were significantly ($p<0.05$) decreased in the matricaria group as compared with placebo, and were comparable to chlorhexidine. The matricaria and chlorhexidine groups also exhibited a significant (p=0.0001) reduction in dental biofilm compared to placebo [Goes 2016].

Antispasmodic effects
In an open multicentre study, 104 patients with gastrointestinal complaints such as gastritis, flatulence or minor spasms of the stomach were treated orally for 6 weeks with an extract (standardized to 50 mg α-bisabolol and 150-300 mg apigenin-7-glucoside per 100 g) at a daily dose of 5 mL. Subjectively evaluated symptoms improved in all patients and disappeared in 44.2% of patients [Stiegelmeyer 1978].

Wound healing effects
In an open study, 147 female patients episiotomized during childbirth were treated for 6 days with either an ointment containing 2% of an ethanolic extract (2.75:1; minimum 10 mg/g essential oil and 3.5 mg/g α-bisabolol) or a 5% dexpanthenol cream. The healing effect of the two preparations was comparable [Kaltenbach 1991].

In a randomized, double-blind, placebo-controlled study involving 14 otherwise healthy patients, weeping dermatoses following dermabrasion of tattoos were treated topically with a fluid extract (standardized to 50 mg of α-bisabolol and 3 mg of chamazulene per 100 g). After 14 days, the decrease in weeping wound area and the improvement in drying tendency were both significant ($p<0.05$) in the verum group [Glowania 1987].

In a randomized, open, comparison study, 120 patients with second degree haemorrhoids were treated with rubber band ligature alone, rubber band ligature with anal dilator and vaseline, or rubber band ligature with anal dilator and an ointment containing an extract of matricaria flower (not further specified). The last group showed the best results in amelioration of haemorrhage, itching, burning and oozing [Förster 1996].

Sedative effects
In a randomized, double-blind, placebo-controlled study, 57 patients with mild to moderate generalized anxiety disorder were treated with capsules containing either 220 mg of a standardised dry extract (1.2% apigenin; n=28) or placebo (n=29) once daily for the first week and twice daily for weeks 2 to 8. Patients with less than a 50% reduction in total HAM-A score (versus baseline) received 3 capsules daily in week 3 and 4 capsules daily in week 4, and if necessary 5 capsules from weeks 5 to 8. The verum group showed a significantly (p=0.047) greater reduction in mean total HAM-A score and a favourable change in the secondary outcomes measured [Amsterdam 2009].

In a randomized, double-blind, placebo-controlled study, 34 patients (aged 18 to 65) with a history of at least 6 months of primary insomnia (meeting DSM-IV criteria) were treated with 3 tablets of either a dry hydroethanolic extract (90 mg per tablet; 6:1 v/v; 70% ethanol; standardized to 2.5 mg of (-)-α -bisabolol and ≥ 2.5 mg of apigenin per tablet) or matching placebo, twice daily for 28 days. Sleep diaries were completed for the 7 days prior to treatment and for days 21 to 28, while secondary objectives were measured at baseline and day 28. While there were no significant between group differences, the verum group did show modest improvements in sleep latency, number of night-time awakenings and day-time functioning measures [Zick 2011].

A two-phase study involving 179 patients with moderate to severe generalized anxiety disorder (GAD-7 score ≥10) has been reported in three different publications: study design [Mao 2014], phase one [Keefe 2016] and phase 2 [Mao 2016]. The first phase involved an open study with all patients receiving 3 capsules of an extract daily for 8 weeks. Each capsule contained 500 mg of a dry hydroethanolic (70%; DER 4:1) extract (equivalent to 2 g of flower; corresponding to 6 mg of total apigenin-7-glucoside). The primary outcome was to identify responders at week 8, defined as those with ≥ 50% reduction in baseline GAD-7 score and final CGI-S score of 1 to 3 (normal to mild). Responders were given the extract for a further 4 weeks. Patients who still met the responder criteria at the end of week 12 were entered into the phase 2 randomized, double-blind, placebo-controlled study to assess time to relapse and relapse rate; patients continued to receive treatment with either the extract or placebo for a further 26 weeks. Non-responders were discontinued from the trial.

Of the 151 patients that completed the initial 8 weeks of treatment, 104 (58.1%) met the responder criteria; 23.5% of the subjects responded quickly, meeting the responder criteria after only 2 weeks of treatment. By week 8 there were also significant ($p<0.001$) reductions in GAD-7 and HAM-A scores, and several other secondary outcome scores. Of the 93 responders continuing to the phase 2 trial, 46 continued to receive the extract and 47 were switched to placebo. The extract led to a non-significant reduction in relapse of GAD symptoms compared to placebo: 15.2% of the extract group relapsed compared to 25.5% of the placebo group; mean time to relapse was 11.4±8.4 weeks for the extract compared to 6.3±3.9 weeks for placebo. However, compared to placebo the extract group experienced a significantly smaller increase in GAD-7 scores (p=0.0032) and better psychological well-being (p=0.013) [Mao 2014, 2016, Keefe 2016].

In a randomized, single-blind, placebo-controlled study, 60 nursing home residents over the age of 60, with a Pittsburgh

Sleep Quality Index (PSQI) of ≥ 5, were treated with 200 mg of a dried ethanolic (70%) extract (n=30) or placebo (n=30) twice daily for 28 days. PSQI was assessed immediately before treatment commenced (T1), 2 weeks after beginning treatment (T2), immediately after treatment finished (T3) and 2 weeks after completion of treatment (T4). The mean PSQI score was significantly ($p<0.05$) decreased in the verum group compared to control at T3 and T4, but not at T2 [Adib-Hajbaghery 2017].

Other effects

In a randomized, double-blind, controlled study, 90 students with premenstrual syndrome (PMS) received either 100 mg of an ethanolic extract (not further specified) or 250 mg of mefenamic acid, 3 times daily for 2 cycles (from day 21 of their cycle until the next onset of menstruation). A significant ($p<0.0001$) decrease in mastalgia was observed after the first and second cycles compared to baseline for chamomile (10.5±21.7% and 13.7±201.4%) and mefenamic acid (12.1±24.7% and 13.8±24.0%). There was no significant difference between the chamomile and mefenamic acid groups. The chamomile extract was significantly ($p<0.001$) more effective at reducing psychological symptoms of PMS than mefenamic acid [Sharifi 2014 A&B].

In a randomized, single-blind, placebo-controlled study, 64 patients with type 2 diabetes mellitus (aged 30 to 60 years) were treated with either a tea (3 g/150 mL hot water; n=32) or an equivalent amount of warm water as placebo (n=32), three times daily after meals for 8 weeks. Glycosylated haemoglobin ($p=0.03$), serum insulin ($p<0.001$), homeostasis model assessment index ($p<0.001$), total cholesterol ($p=0.001$), triglycerides ($p<0.001$) and LDL cholesterol ($p=0.05$) were significantly decreased compared to control after the treatment [Rafraf 2014].

The same study showed that total antioxidant capacity, superoxide dismutase, glutathione peroxidase and catalase activities were significantly ($p<0.05$) increased by 6.8%, 26.2%, 36.7% and 45.1% respectively, compared to control. There was also a significant ($p<0.001$) decrease in malondialdehyde adducts (MDA), a marker of hyperglycaemia, compared to baseline and to control [Zemestani 2016].

In a randomized, double-blind, placebo-controlled study, 80 children (aged 6 to 18; mean age for verum and placebo: 9.5±1.9 and 9.9±2.5 years respectively) with monosymptomatic nocturnal or daytime enuresis were treated topically for 6 weeks with either an aqueous extract evaporated in sweet almond oil, or sweet almond oil alone as placebo (6 drops on the perineal and suprapubic area before sleeping). The mean frequency of enuresis was significantly lower in the verum group as compared to placebo after 2, 4 and 6 weeks of treatment ($p<0.001$, $p=0.03$, $p<0.001$ respectively) [Sharifi 2017].

In a randomized, double-blind, placebo-controlled, cross-over study, 72 migraine patients without aura completed treatment with verum and placebo 'oleogels' (oil preparations mixed with colloidal silicon dioxide). The verum oleogel contained a preparation in which 200 g of flowers were combined with 2.5 L of water and the essential oil extracted and saved, the remaining filtered aqueous extract was then boiled in 167.5 mL of sesame oil until all water was evaporated; the remaining oil and essential oil were combined and then formulated into the oleogel [Zargaran 2017]. The placebo used 10% of the chamomile oil preparation in liquid paraffin and subsequently formulated into an 'oleogel'.

Patients applied 2 mL of one of the oleogels topically to the forehead, temporal area and behind the ears when a migraine attack started. After 2 treatments there was a 14-day washout period followed by a change from verum to placebo treatment or vice versa. Results from VAS questionnaires showed that pain, nausea, vomiting, photophobia and phonophobia were significantly ($p<0.001$) decreased after 30 min in the verum group compared to placebo [Zargaran 2018].

Pharmacokinetic properties

After cutaneous administration of [^{14}C](–)-α-bisabolol to mice, 82% of the radioactivity was found in the urine [Hahn 1987, Hölzl 1985].

Apigenin and luteolin were also readily absorbed by the skin. Skin penetration studies applying hydroethanolic solutions of apigenin and luteolin to the upper arms of 9 healthy, female volunteers gave steady state fluxes of 10.31 ng/min/cm² and 6.1 ng/min/cm² respectively [Merfort 1994].

After oral administration of apigenin-7-glucoside to rats, free apigenin was detected in the urine [Griffiths 1972a].

After oral administration of 40 mL of a hydroethanolic extract (containing 225.5 mg of apigenin-7-glucoside, 22.5 mg of apigenin, 15.1 mg of herniarin per 100 mL) to a female volunteer, no flavones could be detected in blood plasma nor in 24-hour urine, while herniarin was found in both (max. plasma concentration of ca. 35 ng/mL; 0.324 mg in 24-hour urine) [Tschiersch 1993].

In germ-free rats, no hydrolysis of flavone glycosides could be observed; obviously intestinal microflora can affect the cleavage of the glycosidic bonds [Griffiths 1972a,b]. Furthermore, orally administered apigenin was detected in the blood serum of animals [Redaelli 1980].

Preclinical safety data

The acute oral LD_{50} of matricaria flower oil in rats and the acute dermal LD_{50} in rabbits exceeded 5 g/kg. No irritant effects of the oil were observed after application to the skin of nude mice [Opdyke 1974].

In a 48-hour patch test in volunteers, matricaria oil neither caused skin irritation nor were there any discernible sensitization reactions or phototoxic effects. Matricaria oil has been granted GRAS status by FEMA and is approved by the FDA for use in food and cosmetics [Opdyke 1974].

The acute oral toxicity of (–)-α-bisabolol in mice and rats was very low, the LD_{50} being about 15 mL/kg. A six-week subacute toxicity study showed that the lowest toxic oral dose of (–)-α-bisabolol in rats and dogs was between 1 and 2 mL/kg. Oral doses up to 1 mL/kg of ((–)-α-bisabolol produced no discernible effects on the prenatal development of rats or rabbits. No malformations were found at any of the tested dose levels [Habersang 1979].

The acute intraperitoneal LD_{50} of *cis*- and *trans*-en-yne-dicycloether is 670 mg/kg [Ammon 1992]. In the Ames test, apigenin and an aqueous matricaria flower extract showed no mutagenic or toxic activity [Rivera 1994, Birt 1986].

No genotoxicity was found in mice after oral administration of essential oil up to 500 mg/kg b.w. [Hernandez-Ceruleos 2010].

Allergenicity

Based on the fact that matricaria flower generally contains no, or only traces of, the sesquiterpene lactone anthecotulide and that millions of people come into contact with matricaria flower daily, allergic reactions due to matricaria flower can be considered to be extremely rare [Hausen 1992, Rudzki 2000]. However, cross-reactions with other sesquiterpene lactone-containing plants are common [Hausen 1992]: 2 reports of a

patient allergic to *Artemisia vulgaris* mention severe anaphylactic reactions following ingestion of matricaria flower infusions and after eye washing with similar infusions [Sánchez 1992, Foti 2000]; 18 of 24 patients with Compositae allergy were also allergic to an ether extract of matricaria flower [Paulsen 1993] ; 11 of 14 patients with Compositae allergy were allergic to an aqueous extract of matricaria flower [de Jong 1998] ; 96 patients from 4800 showed contact hypersensitivity to an ethanolic matricaria flower extract [Dastychová 1992]; 3 case reports mention an allergic reaction to matricaria flower and extract [Rudzki 1998, Jensen-Jarolim 1998, Rodriguez-Serna 1998].

In a study of contact allergy performed with 540 type IV allergic patients, of whom some gave positive reactions to standard phytogenic allergens, none gave a positive reaction to an anthecotulide-free matricaria flower extract [Jablonska 1996].

In a study of 830 patients with contact dermatitis, only 1 patient had a positive reaction to a matricaria flower extract and cream. Even a patient who was highly sensitive to *Anthemis cotula*, and another with oral allergy syndrome and hypersensitive to many plants, tested negative [Rudzki 2000].

These studies demonstrate the importance of using anthecotulide-free matricaria flower.

A 38-year-old Caucasian man developed an episode of severe anaphylaxis with generalized urticaria, angioedema and severe dyspnoea one hour after consuming matricaria tea. Examination showed specific IgE against matricaria. Skin prick test and labial provocation test with matricaria were also positive [Andres 2009].

Clinical safety data
In one clinical trial involving 57 patients with mild to moderate generalised anxiety disorder more adverse events occurred in the placebo arm (22 versus 11 in the verum); 2 discontinued treatment: 1 for allergic reaction (placebo) and 1 for abdominal discomfort (verum) [Amsterdam 2009].

In a study involving 34 patients, no severe adverse events occurred. There was no significant difference between a dry extract and placebo [Zick 2011].

In a study with 40 patients, a mouthwash containing a liquid extract showed no adverse effects [Braga 2014].

In a study with 30 patients, a mouthwash containing 1% of an extract was well tolerated and showed no adverse effects [Goes 2016].

In 2 studies totalling 166 patients, the local application of a dried aqueous extract in sesame oil showed no adverse effects [Shoara 2015; Hashempur 2017].

In a study with 80 children, the local application of an aqueous extract evaporated in almond oil showed no adverse effects [Sharifi 2017].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

Front cover
Title page
Verso
Foreword and Preface
Notes for the Reader

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

MELISSAE FOLIUM

2013

Melissa Leaf

DEFINITION

Melissa leaf consists of the dried leaves of *Melissa officinalis* L. It contains not less than 1.0 per cent of rosmarinic acid ($C_{18}H_{16}O_8$; M_r 360.3), calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Melissa leaf].

Fresh material may be used provided that when dried it complies with the monograph of the European Pharmacopoeia.

CONSTITUENTS

The main constituents are: phenylpropanoids, including hydroxycinnamic acid derivatives such as caffeic and chlorogenic acids, and in particular rosmarinic acid (up to 4%); hydroxybenzoic acids; essential oil (0.05-0.4% V/m) containing monoterpenoid aldehydes, mainly geranial (citral a), neral (citral b) and citronellal; flavonoids including glycosides of luteolin, quercetin, apigenin and kaempferol; monoterpene glycosides; triterpenes including ursolic and oleanolic acids [Pellecuer 1981; Tittel 1982; Enjalbert 1983; Dorner 1985; Mulkens 1985; 1987a; 1987b; Koch-Heitzmann 1988; Mulkens 1988; Schultze 1989; Baerheim-Svendsen 1989; Lamaison 1991a; 1991b; Patora 2002; Karasova 2005; Mencherini 2007; Marques 2009; Mencherini 2009; Hänsel 2010].

CLINICAL PARTICULARS

Therapeutic indications

Internal use
Tenseness, restlessness and irritability; symptomatic treatment of digestive disorders such as minor spasms [Stahl-Biskup 2009; Fintelmann 2009].

External use
Herpes labialis (cold sores) [Wölbling 1984; Vogt 1991; Wölbling 1994; Koytchev 1999].

Posology and method of administration

Dosage

Oral use
1.5-4.5 g of the drug as an infusion, two to three times daily [Stahl-Biskup 2009; Fintelmann 2009]. Tincture (1:5 in 45% ethanol), 2-6 mL three times daily [Wölbling 1994; Brendler 2005]. Fluid extract (1:1 in 45% ethanol quantified to at least 500 µg/mL citral) 60 drops/day [Akhondzadeh 2003]. Other equivalent preparations.

Cutaneous use
Cream containing 1% of a lyophilised aqueous extract (70:1) two to four times daily [Wölbling 1984; Vogt 1991; Wölbling 1994; Koytchev 1999].

Method of administration
For oral or cutaneous use.

Duration of administration

Oral use
No restriction.

Cutaneous use in *Herpes labialis*
From prodromal signs to a few days after the healing of lesions.

E/S/C/O/P MONOGRAPHS

Contraindications
None reported.

Special warnings and special precautions for use
None required.

Interaction with other medicinal products and other forms of interaction
None reported.

Pregnancy and lactation
In accordance with general medical practice the product should not be taken orally during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antispasmodic activity
A hydroethanolic extract (30% ethanol; 1:3.5) from melissa leaf significantly inhibited histamine-induced contractions in isolated guinea pig ileum ($p<0.05$). The frequency and maximal force of spontaneous peristaltic movements were also decreased in comparison to solvent control [Heinle 2006].

In contrast, a similar extract (30% ethanol; 1:2.5-3.5) at concentrations of 2.5 mL and 10 mL/L did not show any significant antispasmodic activity when tested on acetylcholine- and histamine-induced contractions of guinea pig ileum [Forster 1980].

A hydroethanolic dry extract (ethanol-free lyophilisate; not further specified) at concentrations of 24 to 188 µg/mL led to minor but significant increased contractions in the fundus and corpus of guinea pig stomach ($p<0.05$). The contractile response in distal stomach motility in the antrum was more pronounced; at 94 µg/mL the mean increase in antral contraction amplitude was 177.3%. This effect was immediate, long-lasting and fully reversible after wash-out [Schemann 2006].

An aqueous dry extract produced a concentration-dependent relaxation in phenylephrine-precontracted thoracic aorta rings with intact endothelium from rats. This effect was abolished by L-N^G-nitroarginine methyl ester (L-NAME) and significantly reduced by glibenclamide and indomethacin ($p<0.05$). No relaxation was observed in de-endothelised phenylephrine-precontracted rings [Ersoy 2008].

Essential oil of melissa leaf showed spasmolytic activity when tested on isolated guinea pig ileum, rat duodenum and vas deferens, and on the jejunum and aorta of rabbits [Debelmas 1967; Wagner 1973]. It also had relaxant effects on guinea pig tracheal muscle (EC_{50}: 22 mg/L) and inhibited phasic contractions of an electro-stimulated ileal myenteric plexus longitudinal muscle preparation (EC_{50}: 7.8 mg/L) [Reiter 1985].

Essential oil of melissa leaf reduced contractions in isolated rat ileum induced by 80 mM KCl, 320 nM acetylcholine or 1.28 µM 5-hydroxytryptamine with IC_{50} values of 29 ng/mL, 20 ng/mL and 20 ng/mL respectively [Sadraei 2003].

Antiviral activity
Aqueous extracts exhibited antiviral activity against Newcastle disease virus, SemLiki forest virus, influenza viruses, myxoviruses, vaccinia and *Herpes simplex* virus [Kucera 1967; May 1978; Vanden Berghe 1985; König 1985].

An aqueous extract demonstrated antiviral activity against *Herpes simplex* virus type 1 (HSV-1; IC_{50} 0.025 µg/mL) and type 2 (HSV-2; IC_{50} 0.027 µg/mL), as well as against an acyclovir–resistant strain, in a plaque reduction assay on RC-37 cells. Treatment of the cells prior to infection resulted in a considerable inhibition of the adsorption of all three virus types. A reduction of intracellular virus replication was not observed [Nolkemper 2006].

An aqueous extract showed anti-HIV-1 activity (ED_{50}: 16 µg/mL). The active components in the extract were found to be polar substances. This extract also inhibited giant cell formation in co-culture of Molt-4 cells with and without HIV-1 infection and showed inhibitory activity against HIV-1 reverse transcriptase [Yamasaki 1998].

An infusion (10 g/100 mL) exhibited a concentration-dependent activity against the infection of HIV-I in T-cells, in primary macrophages and in tonsil histocultures. After incubation of prototypic X4 HIV-1_{NL4-3} with the extract (0.006 to 6%) and addition to human T-lymphoblastoid cell line Sup-T1, productive HIV-1 infection was assessed by the p24 concentration. The IC_{50} for HIV replication was 0.045%, the CC_{50} for Sup-T1 cells was 0.531%. HIV infection was also inhibited in primary human lymphoid aggregate culture and in monocyte-derived macrophages. No antiviral effect on target cells exposed to the extract prior to HIV challenge or on surface-bound virions was observed. A virion-fusion assay demonstrated that HIV-1 entry was impaired after pre-incubation of the virions with the extract [Geuenich 2008].

A methanolic and an aqueous extract (100 mg/mL; not further specified) of melissa leaf were among the most active extracts in an enzymatic assay and inhibited neuroaminidase with IC_{50} values of 0.64 mg/mL and 0.04 mg/mL respectively, as compared to zanamavir with an IC_{50} of 215 µM [Schwerdfeger 2008].

A liquid extract from melissa leaf (1:10; 65 % (V/V) ethanol) was investigated for inhibition of the cytopathogenic effect of *Herpes simplex* virus type 2 (HSV-2) in Vero cells (ATCC CCL-81). Vero cells were infected with the virus and after addition of the extract 48 hours of incubation followed. The extract exhibited a concentration-dependent inhibition of virus replication in infected cells with an IC_{50} between 0.1 and 0.2 mg/mL [Mazzanti 2008].

The infectivity of three different doses of HSV-2 in human larynx epidermoid carcinoma cells (Hep-2 ATCC CCL23) was reduced by the essential oil from melissa leaf (main constituents β-cubebene (15.4%) and β-caryophyllene (14.2%)) at 100 µg/mL [Allahverdiyev 2004].

In a plaque reduction assay in monkey kidney cells, the essential oil of melissa leaf was effective against HSV-1 and HSV-2 and reduced plaque formation when the viruses were pre-treated with the oil. The IC_{50} values were 4 and 0.8 µg/mL respectively. When the oil was applied to the host cells prior to infection, or during intracellular replication, plaque formation was not influenced [Schnitzler 2008].

Antimicrobial activity
Antibacterial activity against several bacteria was shown for aqueous and 50% ethanolic extracts, as well as for petroleum ether, chloroform and ethyl acetate fractions from a 70% methanolic extract [Kwon 2007; Mencherini 2007; Čanadanović-Brunet 2008].

A dichloromethane dry extract displayed antifungal effects against *Rhizopus stolonifer* [López 2007].

Melissa leaf essential oil was active against bacteria, fungi and yeasts [Larrondo 1995; Motiejunaite 2003; Anicic 2005; Mimica-Dukic 2004; Suschke 2007; Chao 2008; Inouye 2009; Hussain 2011].

Receptor-binding activity
Extracts (80% ethanol) of melissa leaf displaced [^{3}H]-(*N*)-nicotine and [^{3}H]-(*N*)-scopolamine from nicotinic and muscarinic receptors in homogenates of human cerebral cortical cell membranes (IC_{50} < 1 mg/mL). Choline, a weak nicotinic ligand (IC_{50}: 3×10^{-4} M), was found in the extracts at concentrations of 10^{-6} to 10^{-5} M. The most potent extract showed a high [^{3}H]-(*N*)-nicotine displacement value with an IC_{50} of 0.08 mg plant material/mL [Wake 2000].

In a similar study in human occipital cortex tissue, the IC_{50} for the displacement of [^{3}H]-(*N*)-nicotine and [^{3}H]-(*N*)-scopolamine from nicotinic and muscarinic receptors by a standardized extract (30% methanol; after evaporation the resulting soft extract was mixed with 10% of inert processing agents) were 11 mg/mL and 4 mg/mL respectively [Kennedy 2002].

In a further assay in human occipital cortex tissue using ethanolic (80%) extracts from different samples of melissa leaf, IC_{50} values of 0.18 to 3.16 mg/mL were determined for the displacement of [^{3}H]-nicotine, and 1.46 to 4.31 mg/mL for the displacement of [^{3}H]-scopolamine. A polar fraction of a methanolic extract containing terpenoids and phenolics gave IC_{50} values of 4.0 to 10.0 µg/mL for the displacement of [^{3}H]-nicotine and a fraction containing ionizable alkaline material provided IC_{50} values of 102.0 to 162.9 µg/mL for the displacement of [^{3}H]-scopolamine [Kennedy 2003].

Neither an aqueous nor a methanolic extract displaced flumenazil from the $GABA_A$ receptor in rat phaeochromocytoma (PC12) cells [López 2009].

The essential oil of melissa leaf inhibited the binding of [^{35}S]-t-butylbicyclophosphorothionate (TBPS) to the rat forebrain $GABA_A$ receptor channel with an IC_{50} of 40 µg/mL, but had no effect on N-methyl-D-aspartate, α-amino-3-hydroxy-5-methyl-4-isoxazolepropionate or nicotinic acetylcholine receptors. The oil led to a dose-dependent reversible inhibition of GABA-induced currents in primary cultures of rat cortical neurons [Abuhamdah 2008].

Melissa leaf oil decreased the binding of [^{3}H]-ketanserin to 5-HT_{2A} receptors, of [^{3}H]-8-hydroxy-N,N-dipropyl-2-aminotetralin to 5-HT_{1A} receptors, of [^{3}H]-pirenzepine to muscarinic receptors and of [^{35}S]-TBPS to the $GABA_A$ site channel and of [^{3}H]-clobenprobit to histamine H_3 receptors. The binding of [^{3}H]-muscimol at the $GABA_A$ receptor agonist site was increased as well as the [^{3}H]-flunitrazepam binding to the $GABA_A$ receptor in rat cortex synaptic membrane preparations. Effects were observed at concentrations of 0.1 and/or 1 mg/mL ($p<0.05$ to $p<0.001$) depending on the origin of the oil [Elliott 2007].

Antioxidant activity
Antioxidant and free radical scavenging properties have been reported for aqueous, hydromethanolic, hydroethanolic and methanolic extracts of melissa leaf in numerous different test systems [Van Kessel 1985; Verweij-van Vught 1987; Lamaison 1990; 1991a; 1991b; Ivanova 2005, Germann 2006, Schempp 2006, Speisky 2006, Bouayed 2007, Kwon 2007, López 2007, Mencherini 2007, Woydylo 2007, Dastmalchi 2008, Kirca 2008, Kulišić-Bilušić 2008, López 2009, Orhan 2009, Pereira 2009, Komes 2011, Spiridon 2011, Koksal 2011, Lin 2012]. An extract prepared by supercritical fluid extraction after removal of the essential oil was active against autoxidation and iron- or EDTA-mediated oxidation of linoleic acid [Marongiu 2004].

Rat phaeochromocytoma cells (PC12) were protected against H_2O_2 toxicity by 60 and 80 µg/mL of a methanolic extract as shown in the MTT and the LDH assay ($p<0.05$). A water extract was ineffective. Both extracts reduced ROS formation in the cells after co-incubation with H_2O_2 [López 2009].

Radical scavenging properties were determined in the DPPH assay for the essential oil of melissa [Mimica-Dukic 2004; Chung 2010].

The n-butanol fraction from a 70% methanolic extract of the flowering aerial parts of melissa showed activity in the DPPH assay, in the hydroxyl radical assay and in the lipid peroxidation system [Čanadanović-Brunet 2008].

Cholinesterase inhibitory effects
A 45% hydroethanolic extract inhibited acetylcholinesterase (AChE) in a time- and dose-dependent manner. In a bioactivity-guided fractionation of this extract the activity was attributed to rosmarinic acid derivatives [Dastmalchi 2009].

Inhibition of butyrylcholinesterase (BChE) by approximately 70% was observed with an essential oil from melissa leaf. The same preparation did not show any activity against AChE [Orhan 2008]. For a 75% ethanolic extract from melissa leaf the same group reported a 40% inhibition of AchE at a dose of 2 mg/mL [Orhan 2009].

A concentration of 100 µg/mL of melissa essential oil led to an 82.5% inhibition of AchE and a 96.1% inhibition of BChE [Chaiyana 2012].

In further studies no or very low acetylcholinesterase inhibition was exhibited by different extracts from melissa leaf [Ferreira 2006; Mukherjee 2007].

Insecticidal effects
A methanolic extract (DER 3.6:1) significantly ($p \leq 0.05$) affected larvae of *Spodoptera littoralis* at a dose of 0.5% (w/v) in an artificial diet. Medium insecticidal activity was shown with an LC_{50} of 3.74% (w/v) [Pavela 2004].

Larvicidal activity against West Nile virus mosquito *Culex pipiens* L. (3rd to 4th instar larvae) was shown by melissa essential oil (LC_{50}: 61.25 µg/mL and LC90 88.62 µg/mL) [Koliopoulos 2010].

Other effects
The viability of foetal hippocampal neurons from rats after treatment with a neurotoxic dose of 3,4-methylenedioxymethamphetamine (MDMA; 1200 µM) was significantly increased by co-treatment with 10 µg/mL of an aqueous melissa leaf extract ($p<0.05$). The increased caspase-3 activity and rate of apoptosis/necrosis after MDMA were reduced by the extract ($p<0.05$) [Hassanzadeh 2011].

An aqueous extract showed inhibitory activity (IC_{50} 0.43 mg/mL) against glutamic acid decarboxylase (GAD), whereas an

ethanolic extract was less active (IC_{50} 1.86 mg/mL). The inhibition of GABA transaminase (GABA-T) was more pronounced (IC_{50} 0.35 mg/mL for the aqueous and IC_{50} 0.79 mg/mL for the ethanolic extract) [Awad 2007].

In a bioactivity-guided approach an ethyl acetate, a methanol and a water extract resulted in an inhibition of GABA-T (IC_{50} 2.55, 0.55 and 0.82 mg/mL, respectively). Rosmarinic, ursolic and oleanolic acids were identified as active components [Awad 2009].

Human thyroid stimulating hormone (TSH)-induced adenylate cyclase activity was inhibited by a lyophilized aqueous extract in Chinese hamster ovary cells transfected with recombinant TSH receptor (87.1% inhibition at 500 µg/mL). A 64% inhibition of TSH binding to its receptor and a 23.9% inhibition of antibody binding to TSH were observed at the same concentration. cAMP production induced by thyroid stimulating antibody was also inhibited by the extract (45.4% inhibition) [Santini 2003].

The viability of mouse thymocytes after 18 to 20 hours incubation with three different doses of an aqueous extract was significantly increased to 109.9 ($p<0.001$), 118.6 ($p<0.0001$) and 112.8% ($p<0.05$) as compared to control [Drozd 2003].

Antiproliferative effects on HeLa cells and MCF-7 cells were observed with different fractions (petroleum ether, chloroform, ethyl acetate, *n*-butanol, water) from a 70% methanolic extract with IC_{50} values of 90 to 520 µg/mL for HeLa cells and 100 to 380µg/mL for MCF-7 cells. The water fraction had no effect on MCF-7 cells up to a concentration of 1 mg/mL [Čanadanović-Brunet 2008].

Melissa essential oil was shown to be cytotoxic against human keratinocytes (HaCaT) and human bronchial epithelial (BEAS-2B) cells with a CC_{50} of 0.0096% and 0.0391% (v/v) respectively, after 4 hours of incubation [Suschke 2007].

An essential oil of melissa demonstrated considerable nematicidal activity against *Meloidogyne incognita*, with EC_{50} values of 9.15 and 6.15 µL/mL after exposure for 24 and 96 hours respectively [Ntalli 2010].

In vivo experiments

Sedative effects
The sedative effect of a lyophilised hydroethanolic (30%) extract administered intraperitoneally to mice has been demonstrated by means of familiar (two compartment) and non-familiar (staircase) environment tests. The effect was dose-dependent up to 25 mg/kg body weight, the latter dose producing maximum effects. Low doses (3-6 mg/kg) of the extract induced sleep in mice treated with an infra-hypnotic dose of pentobarbital and also prolonged pentobarbital-induced sleep. At high doses (400 mg/kg) a peripheral analgesic effect in the acetic acid-induced writhing test, but no central analgesic effect was observed [Soulimani 1991; Soulimani1993].

Melissa essential oil administered intraperitoneally to mice had no effect in the staircase test nor was it active in prolonging pentobarbital-induced sleep [Soulimani 1991]. When administered orally to mice it showed sedative and narcotic effects at doses of 3.16 mg/kg and higher [Wagner 1973].

Anti-inflammatory effects
Oral administration of an aqueous extract to mice at doses of 50, 100, 200 and 400 mg/kg b.w. significantly ($p<0.05$) reduced histamine-induced paw oedema by 64.2, 45.7, 57.6 and 88% at three hours after challenge, respectively. In carrageenan-induced oedema the decrease was 47.6, 48.5, 29.4 and 40.3% respectively, significant ($p<0.05$) only for the two highest doses. At these doses the extract also showed significant antinociceptive effects in the writhing test (61.9, 70.3, 67.8 and 98.5% inhibition; $p<0.05$) and the formalin-induced paw licking test (83.1, 67.4, 73.6, 74.0% inhibition; $p<0.05$) [Birdane 2007].

Behavioural effects
A single oral dose (30, 100 or 300 mg/kg b.w.) of an ethanolic extract (yield 13%) administered to mice did not significantly affect indicators of anxiety in the elevated plus maze model. In contrast, repeat oral treatment for ten days resulted in significant effects at all doses in female mice ($p<0.05$) and at the highest dose in male mice ($p<0.05$). In the forced swimming test single dose administration remained without effect. After 10-day treatment the two higher doses in males, and all three doses in females, resulted in a significant reduction in immobility time during the last three minutes of the observation ($p<0.05$). A significant between-gender difference was found in immobility time ($p<0.01$)[Taiwo 2012].

In male albino mice oxidative stress in the brain was induced by addition of manganese to the drinking water for 90 days. This regimen was followed by co-administration of 100 mg/kg b.w./day of an aqueous hot water extract (corresponding to 30 mg plant material in 100 mL water) in the drinking water for a further 90 days. Co-treatment with the extract significantly ($p<0.05$) attenuated the manganese-induced increase in TBARS levels in the hippocampus and the striatum. The manganese-induced decrease in total thiol content in the hippocampus was completely restored by the extract. The increase in SOD activity in all brain structures after manganese was reduced by the extract, significantly only in the hippocampus ($p<0.05$); the increase in CAT activity after manganese was reduced only in the cortex ($p<0.05$) [Martins 2012].

A 30% ethanolic extract (16.62% hydroxycinnamic acids and 9.32% rosmarinic acid) was administered p.o. to mice at doses of 120, 240 and 360 mg/kg b.w. for 15 consecutive days. In the elevated plus maze test the two higher doses significantly increased the activity ratio and the latency ratios ($p<0.03$ and 0.004). The total activity over 24 hours, during the 12-hours light phase and the 12-hours dark phase, showed no significant difference. No changes were observed in the open field test and in the exploratory activity in the four-hole board [Ibarra 2010].

A 75% ethanolic extract did not demonstrate any effect on scopolamine-induced amnesia in mice [Orhan 2009].

An aqueous extract (DER 3:1) at doses of 25, 75, 150, 300 and 900 mg/kg or the essential oil at doses of 10, 25, 75, 150 and 300 mg/kg b.w. were administered i.p. to mice. In the test on spontaneous motor activity the essential oil did not show any activity. In contrast, the aqueous extract at doses of 75, 150 and 300 mg/kg significantly ($p<0.01$) reduced the motor activity by 49.6%, 46.6% and 66.4%, respectively. In the forced swimming test the aqueous extract caused a significant reduction in immobility ($p<0.01$) at all doses and a significant increase in climbing ($p<0.01$) as compared to control. The essential oil significantly reduced immobility ($p<0.01$) and increased climbing ($p<0.01$) at doses of 25, 75, 150 and 300 mg/kg in a dose-dependent manner. The swimming behaviour was increased dose-dependently as well, but significantly only at the highest dose ($p<0.01$) [Emamghoreishi 2009].

Hepatoprotective effects
Hyperlipidaemia induced in rats by a lipogenic diet and 3% ethanol per day for 42 days resulted in a significant increase of serum cholesterol, total lipids, alanine transaminase (ALAT),

aspartate transaminase (ASAT), alkaline phosphatase (ALP) and in the levels of tissue lipid peroxidation (LPO) ($p<0.0001$) as compared to control on a normal diet. The blood glutathione (GSH) levels were significantly decreased in hyperlipidaemic rats ($p<0.0001$). After two weeks on either a lipogenic or a normal diet, two groups received 2 g/kg b.w. p.o. of a dried hot water extract from melissa leaf daily for a further 28 days. The extract decreased the degenerative changes in the hepatocytes of hyperlipidaemic rats such as vacuolization, piknotic nuclei etc. and had no effect on normal rats as observed by light or electron microscopy. Serum cholesterol levels, serum total lipids, blood glutathione levels, serum ALT, AST, ALP and liver glutathione and lipid peroxidation remained unchanged in rats on a normal diet. After administration of the extract in hyperlipidaemic rats, serum cholesterol, total lipids, ALAT, ASAT, ALP and LPO were significantly ($p<0.0001$) reduced and blood GSH ($p<0.017$) as well as liver GSH ($p<0.0001$) increased at day 42 [Bolkent 2005].

In the same experiment several other parameters were investigated: serum triglycerides, serum uric acid and γ-glutamyltransferase were significantly reduced ($p<0.001$, <0.0001 and <0.0001 respectively) in hyperlipidaemic rats. Decreased catalase and paraoxonase activities in the hyperlipidaemic rats were elevated by the extract ($p<0.0001$). Mean skin total lipids, cholesterol, lipid peroxidation and non-enzymatic glycosylation levels, skin catalase, lactate dehydrogenase, glutathione peroxidase and myeloperoxidase elevated after the lipogenic diet were reduced. Skin glutathione and superoxide dismutase, which decreased in hyperlipidaemic rats, were increased by the extract [Sacan 2007].

Gastroprotective effects

An ethanolic liquid extract was tested for its potential anti-ulcerogenic activity against indomethacin-induced gastric ulcers in rats as well as for its antisecretory and cytoprotective activity. It showed dose-dependent anti-ulcerogenic activity at oral doses of 2.5-10 mL/kg associated with reduced acid output and increased mucin secretion, an increase in prostaglandin E_2 release and a decrease in leukotrienes. The effect on pepsin content was rather variable and did not seem to bear a relationship to the anti-ulcerogenic activity. The anti-ulcerogenic activity of the extract was also confirmed histologically. Cytoprotective effects of the extract could be partly due to its flavonoid content and to its free radical scavenging activity [Khayyal 2001].

A 30% ethanolic extract was administered orally to male Wistar rats one hour before challenge with indomethacin. The extract showed a pronounced anti-ulcerogenic effect at 5 and 10 mL/kg. Acidity, acid output and leukotriene content of gastic juice in pyloric-ligated rats were significantly reduced ($p<0.05$), pepsin content was hardly affected, whereas mucin and prostaglandin E_2 content were increased ($p<0.05$) as compared to the indomethacin-treated control group [Khayyal 2006].

Other effects

Topical treatment with a 1% ethanolic solution of the essential oil of melissa leaf applied to the shaved skin of guinea pigs had a repellent activity against *Anopheles stephensi* comparable to a 15% ethanolic solution of *N,N*-diethyl-*meta*-toluamide (Deet) [Oshagi 2003].

Mice were treated orally with an ethanolic extract (yield 13%) or rosmarinic acid in several different assays assessing anti-nociceptive activity. Abdominal contractions induced by i.p. injection of acetic acid were reduced by the extract in a dose-dependent manner, the effect was significant for doses between 30 mg and 1 g/kg b.w. ($p<0.01$ for 30mg/kg and $p<0.001$ for 100 mg, 300 mg and 1 g). Significant inhibition ($p<0.05$) of the neurogenic (0-5 min) and inflammatory (15-30 min) phases of formalin-induced licking were observed with the same dosages of extract. Glutamate-induced nociception was dose-dependently inhibited by the extract, with an ID_{50} of 198.54 mg/kg b.w. and an inhibition of 62% at 1 g/kg; the mean ID_{50} for rosmarinic acid was 2.64 mg/kg, with a 64% inhibition at 3 mg/kg. Locomotor activity was not influenced by the extract. Pretreatment with naloxone reversed the antinociception caused by morphine in the assay of glutamate-induced pain, but not that caused by the extract. In contrast, pretreatment with atropine reversed the antinociception after administration of the extract, and of pilocarpine and nicotine [Guginski 2009].

A dry extract (20% ethanol; 9:1) was administered orally to mice at daily doses of 50 or 200 mg/kg b.w. for 21 days. A control group received only the vehicle (distilled water). Serum corticosterone and GABA-T levels in homogenates of the subgranular zone of the hippocampal dentate gyrus (DG) were significantly decreased in a dose-dependent manner ($p<0.05$) as compared to control. Cell proliferation in the DG as shown by Ki67 immunohistochemistry was increased by 244.1% and 763.9% after 50 and 200 mg/kg respectively, relative to the control. In neuroblast differentiation in DG the treatment led to a dose-dependent and significant increase of doublecortin-immunoreactive neuroblasts with tertiary dendrites (211.4% and 387.4% relative to control; $p<0.05$). BrdU/calbindin D-28 k double labeled cells (integrated neurons into granule cells in DG) increased to 245% in the treatment group relative to the control [Yoo 2011].

In male BALB/c mice i.p. administration of an extract (60% methanol) at doses of 100, 300, 600, 900 and 1200 mg/kg b.w., 30 minutes before challenge with 90 mg/kg pentylenetetrazole i.p., significantly reduced the onset of general clonus ($p<0.01$ to 0.001), of myoclonic convulsion ($p<0.001$ for all doses) and of tonic-clonic convulsion ($p<0.05$ to 0.001) in a dose-dependent manner. The extract exhibited a bell-shaped protective effect against seizures and mortality (increasing dose-dependently up to 600 mg/kg and decreasing at 900 and 1200 mg) [Hariry 2011].

A dry extract (83% ethanol) was administered i.p. to male rats at a dose of 100 mg/kg b.w. daily for seven days, one hour before exposure to repeated restraint stress. Increased plasma levels of cortisol, malonyldialdehyde and protein carbonyl and cerebral nitric oxide exhibited in untreated animals were significantly reduced by the extract ($p<0.05$). The stress-dependent decrease in antioxidant defense systems was improved by the extract as shown by its influence on the cerebral level of reduced glutathione, glutathione-S-transferase and catalase as well as on plasma β-carotene and vitamins A, C and E [Ozkol 2011].

An aqueous extract was administered orally or subcutaneously to BALB/c mice for four days. On day 1 the animals underwent immunization with ram erythrocytes. On day 5 blood samples were taken for an active haemagglutination test in which no immunomodulating activity was observed irrespective of the route of administration. However, the number of splenocytes forming spontaneous E rosettes with ram erythrocytes was significantly increased with both routes of administration ($p<0.0001$) compared to control [Drozd 2003].

Male C57BL/ksJ-*db/db* mice received 0.0125 mg of melissa essential oil with their food for 6 weeks. Blood glucose levels decreased significantly after 3 weeks ($p<0.05$) and by up to 64.6% after 6 weeks ($p<0.001$) as compared to control. Serum insulin levels were significantly increased in comparison to control ($p<0.05$) at weeks 3 and 6. The essential oil also improved glucose tolerance as determined at week 6, with blood glucose levels in the treated animals significantly lower at 0, 15 and 120 min after glucose loading ($p<0.05$ to $p<0.001$). Body weight and

total fat content did not differ from control after 6 weeks. Gene and protein expression of hepatic glucose-regulating enzymes explained the decreased glucose concentrations by stimulation of hepatic GCK activity and a decrease of G6Pase and PEPCK. The mRNA expression of hepatic GLUT4 and SREBP-1c as well as of adipocyte GLUT4, PPAR-α, PPAR-γ and SREBP-1c was increased significantly ($p<0.05$ to $p<0.001$). After 6 weeks, plasma triacylglycerol concentrations were significantly lower ($p<0.05$) as compared to control. No significant differences were observed in plasma total cholesterol or HDL-cholesterol [Chung 2010].

Pharmacological studies in humans

A randomized, double-blind, placebo-controlled, crossover study was carried out in 20 healthy volunteers (mean age 19.2 years). The participants attended 4 days of treatment, receiving a single oral dose of either placebo or 300, 600 or 900 mg of a standardized extract (30% methanol; after evaporation the resulting soft extract was mixed with 10% of inert processing agents). Each treatment day was followed by a 7-day wash-out period. On each treatment day cognitive performance was assessed in a pre-dose testing session (baseline) and 1, 2.5, 4 and 6 hours after treatment using the Cognitive Drug Research computerised test battery and two serial subtraction tasks. Subjective mood was measured by Bond-Lader visual analogue scales. Significant improvement was observed for quality of attention at all times after a dose of 600 mg ($p = 0.0001$ to $p = 0.049$). Significant decreases in the quality of working memory and secondary memory were seen 2.5 and 4 hours after the higher doses ($p = 0.0005$ to $p = 0.05$). Reduction of working memory was more pronounced at 1 and 2.5 hours after the higher doses. Self-rated calmness was elevated significantly after 1 and 2.5 hours by the lowest dose ($p = 0.01$ to $p = 0.05$), while alertness was significantly reduced at all time points ($p = 0.001$ to $p = 0.05$) [Kennedy 2002].

A randomized, double-blind, placebo-controlled, cross-over study was carried out in 20 healthy volunteers (mean age 19.2 years). The participants attended 4 days of treatment, receiving a single oral dose of either placebo or 600, 1000 or 1600 mg of powdered melissa leaf, followed by a 7-day wash-out period. Cognitive performance and subjective mood were assessed by the Defined Intensity Stressor Simulation (DISS), which comprises a set of four concurrent cognitive and psychomotor tasks, on each treatment day in a pre-dose testing session (baseline) and 1, 3 and 6 hours after treatment. Significant improvement was observed for "quality of memory" at the last testing session after a dose of 600 mg ($p = 0.042$) and at 3 and 6 hours after 1600 mg ($p = 0.02$ and $p = 0.003$ respectively). Trends towards an improved performance were observed for the task "secondary memory factor" and some scores in "working memory factor". Significant decreases in the "speed of memory" were seen at all time points after the highest dose ($p = 0.0005$ to $p = 0.05$) and at 3 and 6 hours after treatment with 600 mg ($p = 0.001$ and 0.05 respectively). In the "rapid visual information processing task" significant effects on speed ($p = 0.007$) and accuracy ($p = 0.05$) in terms of false-positive responses were observed. Self-rated calmness was elevated at all time points after the highest dose ($p = 0.05$ to $p = 0.01$) [Kennedy 2003].

In a similar study, 18 healthy volunteers received a dry extract (30% methanol) at single oral doses of 300 or 600 mg extract or placebo. The effects on mood and cognitive performance were assessed by DISS. The three treatments were separated by washout phases of seven days. The higher dose of the extract ameliorated the negative mood effects of the DISS, significantly increased the self-ratings of calmness ($p<0.02$) and reduced those of alertness as compared to placebo. No modulation of the mood effects were seen after the lower dose, but this dose was associated with increased speed and accuracy of mathematical processing [Kennedy 2004].

Improvements in parameters linked to oxidative stress were measured in radiology staff members (occupationally exposed to chronic low-dose ionizing radiation) before and after treatment with an infusion of melissa. The participants (n=55) took the infusion (1.5 g in100 mL) twice daily for 30 days. At the end of treatment plasma superoxide dismutase, glutathione peroxidase and catalase were significantly increased ($p<0.0001$). Significant decreases were observed in plasma myeloperoxidase ($p<0.006$) and lipid peroxidation ($p<0.0001$). Plasma 8-OH-2-deoxyguanosine, as a measure of DNA damage, was significantly reduced ($p<0.001$) [Zeraatpishe 2011].

A 1% ethanolic solution of melissa essential oil protected human skin against *Anopheles stephensi*. The efficacy, based on the number of bites as compared to control, was 60 % [Oshagi 2003].

Clinical studies

In a randomized, double-blind, placebo-controlled, multicentre study, patients (n=42) with mild to moderate Alzheimer´s disease (score of ≥ 12 on the cognitive subscale of Alzheimer´s disease assessment scale (ADAS-cog) and ≤ 2 on the clinical dementia rating CDR) received 60 drops/day of either a 45% ethanolic (1:1) extract from melissa leaf (quantified to at least 500 µg/mL citral) or placebo for 16 weeks. At the endpoint, in the 35 patients who completed the trial (verum n=20, placebo n=15), a significantly better outcome for cognitive function was observed for verum treatment as compared to placebo ($p< 0.001$ for ADAS-cog and CDR) [Akhondzadeh 2003].

In an open study, 20 patients meeting the DSM-IV-TR criteria for primary diagnosis of anxiety disorders and sleep disturbances received 300 mg of a hydroalcoholic dry extract (standardized to more than 15% hydroxycinnamic acid derivatives and more than 7% rosmarinic acid) twice daily for 15 days. The patients were evaluated with the Free Rating Scale for Anxiety (for anxiety and related symptoms) and the Hamilton Rating Scale for Depression (to assess insomnia) at baseline and at the end of the study. The Clinical Global Impression-Improvement (CGI) scale was used for measurement of the overall clinical improvement in anxiety disorders and sleep disturbances. Total anxiety manifestations were reduced significantly by 18% ($p<0.01$). Agitation decreased by 35%, tension by 18% and hyperactivity as well as motor disturbances by 10% each. Anxiety-associated symptoms such as psychosomatic symptoms, eating problems, fatigue, intellectual disturbance and feeling of inferiority, declined in total by 15% ($p<0.01$). Initial insomnia (difficulty falling asleep) decreased by 53%, middle insomnia (waking during the night) by 45% and delayed insomnia (early morning waking) by 28%; the total reduction was 42% ($p<0.01$). Based on the CGI improvement a positive treatment response was experienced by 19 of 20 patients for anxiety disorders and by all patients for insomnia [Cases 2011].

A double-blind, randomized, placebo-controlled, multicentre trial was performed in patients with Alzheimer´s disease (mean age 85.6 years) associated with severe agitation (score ≥ 39 on the Cohen Mansfield Agitation Inventory). The patients were randomized to one of 3 groups: verum oil and placebo tablets (n=35), donepezil (5 mg/day increasing to 10 mg/day after one month orally) and placebo oil (n=35), or placebo oil and placebo tablets (n=36). A lotion containing either 200 mg of melissa essential oil (verum) or sunflower oil (placebo) was massaged into the skin of the hands and upper arms of the patients twice daily. No signficant differences in the Pittsburgh

Agitation Scale, the Barthel Scale of Activities in Daily Living or the Neuropsychiatric Inventory were observed compared to baseline after 4 and 12 weeks of treatment and between the three groups. A significant difference between melissa and donepezil was seen in quality of life measured with the Blau QOL Scale: a significantly lower QOL occurred in the donepezil group (p=0.033) at week 12 [Burns 2011].

A 4-week multicentre, double-blind, placebo-controlled study involved 72 patients of mean age 78.5 years with clinically significant agitation in the context of severe dementia. The patients were treated topically twice daily with a lotion containing 10% of melissa essential oil, providing a daily total of 200 mg of the oil (n = 36), or a placebo lotion (n = 36). Lotion was gently applied to the patient's face and both arms as an aromatherapy treatment. Changes in agitation were determined by the Cohen-Mansfield Agitation Inventory (CMAI) score. Improvements in the CMAI total score (35% reduction in the verum group and 11% in the placebo group) were significantly greater in the verum group ($p<0.0001$). A 30% improvement in CMAI score was attained by 21 subjects in the verum group compared to only 5 in the placebo group ($p<0.0001$). Quality of life indices measured by Dementia Care Mapping also improved significantly in the verum group; compared to the placebo group the percentage of time spent socially withdrawn was reduced ($p<0.005$) and time engaged in constructive activities increased ($p<0.001$) [Ballard 2002].

In a multicentre, open, controlled study involving 115 patients, a cream containing 1% of a lyophilised aqueous extract from melissa leaf (70:1) significantly reduced the healing time of cutaneous *Herpes simplex* lesions ($p<0.01$). It also significantly extended the intervals between recurrences of infection compared to other external virustatic preparations containing idoxuridine and tromantidine hydrochloride ($p<0.01$) [Wölbling 1984; Wölbling 1994]. These effects, particularly a significant reduction in the size of lesions within 5 days ($p = 0.01$), were confirmed in a multicentre, double-blind, placebo-controlled study on 116 patients [Vogt 1991; Wölbling 1994].

A randomized, double-blind, placebo-controlled study was carried out using a cream containing 1% of a melissa leaf dry extract (70:1) standardized in terms of antiviral potency. Sixty-six patients with a history of recurrent *Herpes simplex* labialis (at least four episodes per year) were treated topically; 34 of them with verum cream and 32 with placebo. The cream was applied to the affected area 4 times daily over 5 days. A symptom score (ranging between 0 and 9), derived by combination of the severity ratings for complaints, size of affected area and number of blisters on day 2 of therapy, was used as the primary target parameter. There was a significant difference ($p<0.05$) in scores for the primary target parameter between treatment groups: verum 4.03 ± 0.33 (3.0); placebo 4.94 ± 0.40 (5.0); values given are the mean ± SEM (median) of the symptom scores on day 2. The significant difference in symptom scores on the second day of treatment is of particular importance because the complaints in patients suffering from *Herpes labialis* are usually most intensive at that time [Koytchev 1999].

Pharmacokinetic properties

After incubation with an extract, a dose-dependent absorption of rosmarinic acid as a marker for melissa leaf was shown *ex vivo* using the everted gut sac technique, and *in vitro* in the Caco-2 cell model [Kelber 2006].

Preclinical safety data

A hydroethanolic melissa extract (50% ethanol), a juice of fresh melissa, rosmarinic acid and a sulphated triterpene, in a solution of phosphate buffer (PBS), were tested on reconstituted human epidermis, a model validated to classify skin irritants. Compared to the control (PBS) group, after 15 min exposure to the test solutions and a period of 42 hours of recovery, no decrease in epidermis viability was observed as measured in the MTT assay or in trans-epithelial electrical resistance, a measure for the barrier function of the epithelium. No increased release of IL-1α occurred as compared to control [Mencherini 2009].

Melissa essential oil did not cause any symptoms of irritation at a concentration of 25% when applied to chorioallantoic membrane. The endpoint of evident haemorrhage was seen after 5 min. incubation with 35% of the oil [Suschke 2007].

Mutagenicity
A tincture (ethanol 70%, 1:5) of melissa leaf gave negative results in the Ames test using *Salmonella typhimurium* TA 98 and TA 100 strains with or without metabolic activation [Schimmer 1994]. No genotoxic effects from a 20% tincture of melissa leaf were detected in a somatic segregation assay using the diploid strain *Aspergillus nidulans* D-30 [Ramos Ruiz 1996].

Male CF-1 mice were treated orally with either an extract (45% ethanol; 1:5) at 250 and 500 mg/kg b.w. per day, or an infusion (0.6 g of the drug in 20 mL) at 100 mg solid matter/kg b.w. per day for 14 days prior to an i.p. injection of saline or the alkylating agent methylmethansulfonate (MMS; 40 mg/kg b.w.). Neither genotoxic nor mutagenic effects were demonstrated in the blood and bone-marrow of animals treated with the melissa extracts plus saline compared to the negative control, as evaluated in the comet assay and the micronucleus test . After both doses of the extract a significant decrease in MMS-induced DNA damage was observed ($p<0.05$ to 0.001) in the comet assay. In the micronucleus test the higher dose of the extract significantly decreased the number of polychromatic erythrocytes after challenge ($p<0.05$), thus suggesting an antimutagenic effect [Cassettari de Carvalho 2011].

Clinical safety data

After single doses of 300 and 600 mg of a 30% methanolic extract, administered to healthy volunteers (n=18), no adverse effects were observed [Kennedy 2004].

No significant differences in side effects were observed between verum (n = 21; 60 drops per day of a 45% ethanolic (1:1) extract) and placebo during a 16 weeks trial. Only agitation was more common in the placebo group (p=0.03) [Akhondzadeh 2003].

In a double-blind, placebo-controlled, randomized trial in Alzheimer patients, after topical application of a lotion containing melissa essential oil (n = 35; 200 mg of the oil twice daily) two serious adverse events (not further specified) were reported [Burns 2011].

No adverse effects on the skin of four volunteers were observed during the study and for one month after the topical application of a 1% ethanolic solution of melissa essential oil [Oshagi 2003].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me, on behalf of my colleagues in ESCOP, to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

MENTHAE PIPERITAE FOLIUM 2019

Peppermint Leaf

DEFINITION

Peppermint leaf consists of the whole or cut dried leaves of *Mentha × piperita* L. The whole drug contains not less than 12 mL/kg of essential oil. The cut drug contains not less than 9 mL/kg of essential oil.

The material complies with the monograph of the European Pharmacopoeia [Peppermint Leaf].

Fresh material may also be used, provided that when dried it complies with the monograph of the European Pharmacopoeia.

CONSTITUENTS

The main active component is essential oil (0.5-4%), of which the principal constituent is usually menthol, in the form of (-)-menthol (30.0-55.0%) with smaller amounts of stereoisomers such as (+)-neomenthol (2.5-3.5%) and (+)-isomenthol (approx. 3%), together with menthone (14.0-32.0%), isomenthone (1.5-10.0%), menthyl acetate (2.8-10.0%), 1,8-cineole (3.5-8.0%), limonene (1.0-3.5%), menthofuran (1.0-8.0%), pulegone (max 3.0%) and other monoterpenes. Small amounts of sesquiterpenes, notably β-caryophyllene, germacrene D and viridoflorol [Lawrence 1993; Peppermint Oil; Stahl-Biskup 2011, 2016].

Various flavonoids including luteolin and its 7-glycosides, rutin, hesperidin, eriocitrin and highly oxygenated flavones; phenolic acids such as rosmarinic acid and lithospermic acid and small amounts of triterpenes [Croteau 1973; Hoffmann 1984; Litvinenko 1975; Jullien 1984; Barberan 1986; Duband 1992; Hänsel 2010; Guédon 1994; Fecka 2007].

CLINICAL PARTICULARS

Therapeutic indications

Symptomatic treatment of digestive disorders such as dyspepsia, flatulence and gastritis [Demling 1969; Forster 1980; Forster 1983; Bradley 1992; Hänsel 2010; Stahl-Biskup 2016]. In these indications, the efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adults: As an infusion, 1.5-3 g of the drug to 150 mL of water, three times daily [Bradley 1992; Stahl-Biskup 2016]. Tincture (1:5, 45% ethanol), 2-3 mL, three times daily [Bradley 1992].
Elderly: Dose as for adults.
Children from 4 years of age, daily dose as infusions only: *4-10 years*: 3-5 g; *10-16 years*: 3-6 g [Dorsch 2002].

Method of administration
For oral administration.

Duration of administration
If symptoms persist or worsen, medical advice should be sought.

Contra-indications
Known hypersensitivity to peppermint or to menthol.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

E/S/C/O/P MONOGRAPHS

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties
The pharmacological actions of peppermint leaf are largely, but not exclusively, attributable to the essential oil; other components such as flavonoids also appear to play a role [Bradley 1992; Stahl-Biskup 2016]. Pharmacodynamic data relating to the essential oil are given in the monograph on Peppermint Oil.

In vitro experiments

Antispasmodic activity
An extract (ethanol 30%; not further specified) exhibited antispasmodic activity at concentrations of 2.5 and 10.0 mL/L, causing significant and dose-dependent increases in ED_{50} values for acetylcholine- and histamine-induced contractions of isolated guinea pig ileum ($p<0.01$ and $p<0.0005$ respectively for histamine-induced contractions), and a significant decrease in the maximum possible contractility ($p<0.05$ and $p<0.001$ respectively for histamine-induced contractions). The effect of the extract at 10.0 mL/L corresponded to that of 1.6 µg/L of atropine [Forster 1980]. A similar peppermint leaf extract inhibited carbachol-induced contractions of isolated guinea pig ileum [Forster 1983].

A total flavonoid fraction from peppermint leaf, dissolved in water so that 1 mL corresponded to about 0.5 g of dried leaf, inhibited barium chloride-induced contractions of isolated guinea pig ileum [Lallement-Guilbert 1970].

Antimicrobial activity
A methanolic extract (not further specified) inhibited growth of *Candida albicans* with a MIC value of 7 µg/mL [Höfling 2010].

A dichloromethane fraction of a methanolic extract (not further specified) showed inhibitory activity against *Giardia lamblia* trophozoites with an IC_{50} of 0.75 µg/mL after 48 hours of incubation compared to metronidazole with an IC_{50} of 0.8 µg/mL after 24 hours of incubation. In an adherence inhibition assay the same fraction at a concentration of 1 µg/mL significantly ($p<0.01$) reduced adherence of trophozoites on coverslips after 48h [Vidal 2007].

Three aqueous extracts (not further specified) significantly ($p<0.01$) reduced the growth of *Chlamydia pneumoniae* in the range of 51.2-69.5% of rifampicin activity (at a dose of 9 ng/sample). The IC_{50} values ranged between 98 und 224 µg/mL [Kapp 2013].

Antiviral activity
An aqueous extract (not further specified) exhibited activity against HSV-1 and HSV-2 with IC_{50} values of 0.041 µg/mL and 0.227 µg/mL respectively, in a plaque reduction assay using RC-37 cells. Plaques were reduced by > 90% for HSV-1 and HSV-2 and > 85% for an acyclovir-resistant strain of HSV-1. Effects were time-dependent and best results were observed after two hours of incubation prior to the infection. The effective concentrations were far below cytotoxic concentrations (EC50 =107 µg/mL) [Nolkemper 2006].

An infusion (10 g/100 mL) added to HIV-1 virions prior to infection of cells led to a concentration-dependent reduction of HIV-1 virion replication in Sup-T1 T-cells ($IC_{50}=0.190 \pm 0.124\%$ [1%=1mL stock-solution/100mL culture medium]), C8166 T-cells ($IC_{50}=0.026 \pm 0.016\%$) and primary human lymphoid aggregate culture (HLAC) from tonsil tissue ($IC_{50}=0.666 \pm 0.156\%$) monitored by p24 ELISA. These concentrations did not affect cell viability. Extracts were active against infection of virions carrying diverse envelopes (X4 and R5 HIV-1), but not against non-enveloped adenovirus. The extract induced an increase of the virion's density [Geuenich 2008].

Other effects
Acetonitrile and methanolic extracts (not further specified) showed radical-scavenging activity in DPPH assay with IC_{50} values of 0.24 mg/mL and 0.21 mg/mL respectively [Dorman 2009].

A chloroform and an ethyl acetate extract (not further specified) were tested for their cytotoxicity against cervical adenocarcinoma (HeLa), breast adenocarcinoma (MCF-7), T-cell lymphoblast (Jurkat), urinary bladder carcinoma (T24), colon adenocarcinoma (HT-29), pancreatic adenocarcinoma (MIAPaCa-2), normal lung fibroblast (IMR-90), and kidney epithelial (HEK-293) cells using the Annexin-V-FITC/PI assay. Both extracts showed significant increases ($p<0.01$) in the apoptotic index within all cancer cell lines. No effect was observed in normal IMR-90 and HEK-293 cells [Jain 2011].

In vivo experiments

Choleretic effects
In experiments with cannulated dogs, peppermint tea (0.4 g/kg b.w.) increased the secretion of bile [Steinmetzer 1926]. Flavonoids, as well as the essential oil, contribute to this action [Pasechnik 1966; Pasechnik 1966b; Hänsel 2010].

Mixed flavonoids from peppermint leaf (optimum dose 2 mg/kg) showed choleretic activity in dogs [Pasechnik 1966]. Flavomentin, a flavonoid preparation from peppermint leaf, stimulated bile secretion and the synthesis of bile acids in dogs at doses of 0.5-6 mg/kg (optimum 2 mg/kg) [Pasechnik 1966b].

In experiments with cannulated rats, intravenous injection of a peppermint tea at 0.5 mL/rat or a flavonoid preparation (corresponding to a dose of 3.3 g of peppermint leaf per kg b.w.) proved effective in increasing the amount of bile acids [Lallement-Guilbert 1970].

Anti-ulcerogenic effect
Oral pre-treatment of rats with an ethanolic liquid extract (not further specified) at 2.5-10 mL/kg b.w. dose-dependently protected against oral indometacin-induced gastric ulcers (80% protection at 10 mL/kg); this was confirmed histologically. The extract also had gastric antisecretory and cytoprotective effects; compared to rats treated intraperitoneally with indometacin (10 mg/kg), analysis of the gastric contents of animals pre-treated orally with the extract indicated reduced acid output, an increase in PGE_2 release and a decrease in leukotrienes (all $p<0.05$ at 2.5 mL/kg) [Khayyal 2001].

Antinociceptive effects
An aqueous extract (not further specified) administered i.p. at doses of 200 mg/kg and 400 mg/kg b.w. to albino mice

significantly ($p<0.01$) lowered acetic acid-induced abdominal writhing. There was no significant difference between the two doses. In a hot-plate test, the extract at both doses significantly ($p<0.001$) increased the latency to a response to thermal stimulation compared to controls (20.2% and 17.1% protection respectively) [Taher 2012].

In a similar experiment, a dry extract (ethanol 80%; not further specified) administered orally at 200 mg/kg or 400 mg/kg b.w. to mice significantly reduced acetic acid-induced writhing ($p<0.01$ and $p<0.001$ respectively) as well. The response time of mice to thermal stimulation in the hot-plate test also increased significantly 45 and 60 minutes after i.p. administration of the extract at 400 mg/kg ($p<0.01$ and $p<0.001$ respectively) [Atta 1998].

Anti-inflammatory activity
A dry extract (ethanol 80%; not further specified) showed anti-inflammatory activity against acute and chronic inflammation in rodents. After oral administration, it reduced xylene-induced ear oedema in mice (acute model) by 49% at 200 mg/kg and 50% at 400 mg/kg b.w. (both $p<0.05$). After i.p. administration in the cotton pellet granuloma test in rats (chronic model), only the higher dose of 400 mg/kg had a significant inhibitory effect ($p<0.01$) [Atta 1998].

Sedative effects
A dry aqueous extract (not further specified), administered orally to mice at single doses of 300 or 1000 mg/kg b.w., caused weak sedative effects in several tests: hexobarbital-induced sleep, exploratory behaviour, spontaneous motility and motor coordination. The same extract had a significant diuretic effect in mice at 100 and 300 mg/kg ($p<0.05$), but not at 1000 mg/kg [Della Loggia 1990].

Effects on blood lipid profile
An aqueous extract (not further specified) at a dose of 250 mg/kg b.w. administered orally to rats with fructose-induced hyperlipidaemia significantly ($p<0.05$) decreased elevated body weight and levels of glucose, serum cholesterol, triglycerides, VLDL, LDL as well as the atherogenic index and increased the level of serum HDL. The extract also significantly ($p<0.05$) increased the activity of SOD as well as the concentration of GSH and significantly ($p<0.05$) decreased lipid peroxidation, as shown by a reduced level of TBARS [Badal 2011].

Antiallergic effects
An extract of leaves and stems previously depleted of essential oils by steam distillation (ethanol 50%; not further specified) reduced experimentally increased histamine release by compound 48/80 from peritoneal mast cells of male Wistar rats with an IC_{50} value of 4.72 µg/mL (95% confidence interval 2.54 – 7.65 µg/mL). A fraction of the extract, administered orally at doses of 300 and 1000 mg/kg, significantly ($p<0.01$) decreased sneezing, nasal rubbing and dye leakage induced by an antigen. No significant effect was seen in sneezing and nasal rubbing induced by histamine [Inoue 2001].

Tumour-preventive effects
Male albino mice were divided into 3 groups. The first group (n=8) received no treatment; in the second and third groups (n=36 each) the mice had the ventral and dorsal surfaces of their tongues painted 3 days a week for 9 weeks with the carcinogens 7,12-dimethylbenz[a]anthracene (DMBA) and formaldehyde (starting on day 9); the third group were additionally treated at the same time with an aqueous extract (not further specified) at an oral dose of 1 g/kg b.w. The extract non-significantly reduced dysplastic cellular changes in the tongue epithelium by 61% and inhibited tumour incidence by 100% as compared to group 2 in histological analysis. Immunohistochemical evaluation after 6 weeks showed significantly ($p\leq0.001$) reduced expression of caspase 3 in the extract treated group compared to group 2 [Kasem 2014].

Protective effects against irradiation
Adult male Swiss albino mice were treated orally with an aqueous extract (not further specified) at a dose of 1 g/kg b.w. per day for three days and subsequently exposed to whole-body gamma-irradiation (8 Gy). Ten days after irradiation, pretreatment with the extract showed significant increases ($p<0.001$) in total erythrocyte and leucocyte counts, haemoglobin concentration and haematocrit value compared to irradiation only. Glutathione levels in blood and liver were significantly elevated ($p<0.005$ and $p<0.001$ respectively) in the extract + irradiation group in contrast to the irradiation only group [Samarth 2003].

Irradiated mice showed significantly ($p<0.001$) decreased levels of pronormoblasts and normoblasts of the erythroid series as well as increased levels of leucoblasts and myelocytes compared to normal values, whereas these irradiation-caused changes in blood values were significantly ($p<0.001$) reduced by pre-treatment with the above-mentioned extract [Samarth 2007].

Under the same conditions, the testicles of extract-pretreated, irradiated mice showed normal testicular morphology with regular arrangement of germ cells and a slight degeneration of seminiferous epithelium. There was a significant decrease in the testicular weight of mice exposed to radiation ($p<0.001$) compared to the group treated with distilled water only. Extract pre-treatment plus irradiation led to significantly ($p<0.001$) elevated testicular weight compared to the irradiation only group, 14 days after irradiation. A significant decrease of lipid peroxidation ($p<0.001$) and of acid phosphatase ($p<0.01$) and a significant increase of alkaline phosphatase ($p<0.001$) were also observed in testicular tissue fourteen days after irradiation as compared to irradiated mice without pre-treatment [Samarth 2009].

Swiss albino mice treated orally with an aqueous extract (not further specified) at a dose of 1 g/kg b.w. per day for seven days and subsequently exposed to whole-body gamma-irradiation (6 Gy) showed significantly ($p<0.05$) reduced expression of p53 and up-regulation of Bcl2, as well as significantly ($p<0.05$) reduced levels of G2/M and G0/G1- Phase, and a significantly ($p<0.05$) elevated level of S-phase in CNS cells, compared to an irradiation only group. Concentration of brain DNA, RNA, GSH and SOD significantly ($p<0.05$) increased in the extract-treated irradiated group in contrast to irradiated mice [Hassan 2013].

Other effects
An aqueous extract (not further specified) was administered orally to albino mice at a dose of 1 g/kg b.w. per day for 10 days prior to sodium arsenite intoxication and continuously for 30 days afterwards. Treatment with the extract significantly ($p<0.001$) ameliorated the sodium arsenite-induced decrease in body and liver weight after 30 days. The extract significantly ($p<0.001$) lowered the sodium arsenite-induced enhancement of ALP, acid phosphatase (ACP), SGOT, SGPT and lipid peroxidation. Sodium arsenite-induced declines in LDH activity and GSH level were raised significantly ($p<0.001$) by the extract [Sharma 2007].

An extract (ethanol 70% (V/V); not further specified) at a dose of 100 mg/kg b.w. per day administered orally for seven weeks to female Balb/c mice previously infected with *Schistosoma mansoni* caused significantly ($p<0.05$) increased serum levels of IL-10, INF-γ, IgG2a and IgE and a significant ($p<0.05$) decrease in egg counts in the faeces and intestine, compared to control [Dejani 2014].

Male rabbits were divided into 4 groups (n=6 each) and treated daily for 21 days with either saline (i.m.), gentamicin (80 mg/kg b.w. i.m.), an ethanolic extract (not further specified; 200 mg/kg b.w. p.o.) or the extract and gentamicin together. The significant increases ($p<0.05$ to $p<0.0001$) in the levels of serum creatinine, blood urea nitrogen, serum uric acid and urinary protein in the gentamicin group compared to control were significantly ($p<0.05$ to $p<0.0001$) decreased in the groups receiving the extract. Creatinine clearance, serum potassium and serum calcium levels were significantly ($p<0.05$ to $p<0.0001$) increased in both extract groups compared to the group treated with gentamicin only. Additionally, the extract did not reduce the antimicrobial activity of gentamicin [Ullah 2014].

An aqueous infusion (not further specified) showed antimutagenic activities against hydrogen peroxide in the Somatic Mutation and Recombination Test (SMART) in wings of *Drosophila melanogaster* [Romero-Jimenez 2005].

Pharmacological studies in humans

The carminative action of extracts (not further specified) is due to a reduction in tonus of the oesophageal sphincter, enabling release of entrapped air [Demling 1969].

The metabolic ratio of N-acetyltransferase-2 was significantly ($p<0.05$) reduced after six days by an aqueous extract (2 g dry leaves/200 mL water; not further specified) administered twice daily to healthy volunteers. The extract had no significant influence on the activity of CYP 1A2, CYP 2A6, xanthine oxidase and UDP-glucuronosyltransferase-1A1 and -1A6 [Begas 2017].

Pharmacokinetic properties

Pharmacokinetic data relating to the essential oil are given in the monograph on Peppermint Oil.

Preclinical safety data

After oral administration of an extract (not further specified) to mice (n=12) as a single dose at 4000 mg/kg b.w., none of the animals died and none showed macroscopic signs of toxicity over a 7-day period of observation [Della Loggia 1990].

An infusion (20 g/L) was provided to male Wistar albino rats (n=12) instead of drinking water for 30 days. Histological analysis of kidney tissue showed tubular epithelial cells with slight hydropic degeneration and epithelial cells with pycnotic nuclei and eosinophilic cytoplasm. Moderate tubular dilatation and enlargements in Bowman capsules were observed [Akdogan 2003].

In the same experimental setup, the infusion caused significantly ($p<0.01$) decreased plasma testosterone levels, whereas LH and FSH levels significantly ($p<0.05$) increased. Histological analysis showed changes in germinal epithelium and spermatogenesis arrest. Johnsen testicular biopsy score significantly decreased ($p<0.01$) [Akdogan 2004a].

In a similar trial, the same infusion caused a significant ($p<0.05$) decrease in serum iron and ferritin levels and a significant ($p<0.01$) increase in unsaturated iron-binding capacity [Akdogan 2004b].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

MENYANTHIDIS TRIFOLIATAE FOLIUM 2013

Bogbean Leaf

DEFINITION

Bogbean leaf consists of the dried, entire or fragmented leaves of *Menyanthes trifoliata* L. The material complies with the monograph of the European Pharmacopoeia [Bogbean Leaf].

CONSTITUENTS

The main characteristic constituents are iridoid glycosides - approx. 1% of bitter substances including the iridoid loganin and the seco-iridoids foliamenthin, dihydrofoliamenthin, menthiafolin and sweroside. Maximum concentrations of bitter substances were recorded during flower-bud initiation [Hänsel 1966; Battersby 1968; Gessner 1974; Maksimova 1980; Steinegger 1988; Junior 1989; Wagner 1996; Martz 2009]. Flavonol glycosides such as isoquercitrin, hyperoside and rutin [Krebs 1957; Lebreton 1973; Mel'chakova 1976; Bohm 1986; Wagner 1996], as well as trifolin [Krebs 1958]. Chlorogenic acid and other phenolic acids such as caffeic, ferulic, sinapic, vanillic and protocatechuic acids [Herrmann 1959; Ciaceri 1972; Swiatek 1986]. Coumarins - scopoletin (6-methoxy-7-hydroxycoumarin), scoparone (6,7-dimethoxycoumarin) and braylin [Ciaceri 1972; Adamczyk 1990].

Other constituents include ascorbic acid, tannins [Pamakstyte-Jukneviciene 1971; Maksimova 1980], polysaccharides [Kuduk-Jaworska 2004], polypeptides [Lindholm 2002] and phytosterols [Popov 1969]. The alkaloid gentianine has been reported [Steinegger 1951; Rulko 1969] but may be an artefact [Cordell 1981].

CLINICAL PARTICULARS

Therapeutic indications

As a bitter [BHP 1996; Bruneton 1999] in loss of appetite, peptic discomfort and atonic dyspepsia [Schilcher 2007], as well as for gall bladder and biliary tract disorders [Sweetman 2007].

Posology and method of administration

Dosage

Dried powdered leaf
0.5-2.0 g two to three times daily [BHP 1976; Steinegger 1988; Blaschek 2007].

Cut drug
0.5-1 g as an infusion in 150 mL boiling water taken half-an-hour before meals [Steinegger 1988; Bisset 1994; Blaschek 2007; Wichtl 2009].

Liquid extract (1:1; 25% ethanol)
1-2 mL; two to three times daily [BHP 1976; Steinegger 1988].

Tincture (1:5; 45% ethanol)
1-3 mL; three times daily [BHP 1976; Steinegger 1988; Blaschek 2007].

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.
Not recommended in cases of diarrhoea, dysentery or colitis [BHP 1976; Steinegger 1988; Blaschek 2007].

Special warnings and special precautions for use
None required.

E/S/C/O/P MONOGRAPHS

Interaction with other medicaments and other forms of interaction
None reported. Due to their structure and low content the coumarins are presumed not to interact with anticoagulants [Williamson 2009].

Pregnancy and lactation
In accordance with general medical practice, the product should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Can irritate the stomach and induce vomiting in sensitive individuals [Steinegger 1988; Blaschek 2007].

Overdose
May lead to nausea, vomiting and diarrhoea [Blaschek 2007].

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties
Bogbean leaf is required to have a minimum bitterness value of 3000.

In vitro experiments

Antibacterial activity
A 70%-ethanolic extract (1:5) [Moskalenko 1986] and an aqueous extract [Brantner 1994] of bogbean leaf showed activity against various microorganisms including strains of *Staphylococcus aureus, Bacillus subtilis* and *Escherichia coli*. Using the microdilution broth method MIC values (mg/mL, calculated as the dry residue) were 25.7, 29.4 and 25.7 respectively [Brantner 1994].

Anti-inflammatory activity
Aqueous extracts (0.2 mg/mL) from bogbean leaf produced a low percentage inhibition of prostaglandin biosynthesis (22%) in comparison with 1 µg/mL of indomethacin (88%) and 76 µg/mL of quercetin (96%). In the PAF-exocytosis assay the aqueous extracts (0.25 mg/mL) also produced a low inhibition (35%) when compared to 100 µM of the PAF-inhibitor BN 52021 [Tunón 1995].

Enzymatic activation of iridoid glycosides with β-glucosidase yield an active hydrolysed-iridoid product (H-iridoid). H-loganin prepared from loganin (1mM) preincubated with enzyme (0.5 mM) (iridoid:enzyme=1.0:0.5V/V) showed significant inhibition of thromboxane B_2 formation in intact HEL cells at 10, 50 and 100 µM ($p<0.05$) compared to vehicle only. Significant inhibitory activities were recorded on COX-1 (IC_{50} value of 3.55 µM; $p<0.05$) compared to aspirin (7.23 µM), against PGE_2 at 50 and 100 µM ($p<0.05$) and suppression of TNFα (IC_{50} value of 154.6 µ M; $p<0.05$) compared to vehicle (DMSO) [Park 2010].

Immunomodulatory activity
Tests using human blood-derived lymphocytes and granulocytes showed that some polysaccharide fractions isolated from bogbean leaf were strongly immunostimulatory, while other fractions were potent immunosuppressive and anti-inflammatory agents [Kuduk-Jaworska 2004].

Maturation of human dendritic cells (DCs) in the presence of a lyophilised aqueous extract of *Menyanthes trifoliata* (50 µg/mL) did not affect expression of the surface molecules but reduced the ratio of secreted IL-12p40/IL-10, compared with cells matured in the absence of extracts. Allogeneic $CD4^+$ T cells co-cultured with DCs matured in the presence of an aqueous extract secreted less IFN-γ, IL-10 and IL-17 than $CD4^+$ T cells co-cultured with DCs matured without an extract ($p<0.05$) [Jonsdottir 2011].

In vivo experiments

Anti-inflammatory activity
When applied topically, some of the phenolic acids present in bogbean leaf have shown anti-inflammatory activity against tetradecanoylphorbol acetate (TPA)-induced mouse ear oedema (protocatechuic acid, 71.6% inhibition, $p<0.001$; ferulic acid, 71.0% inhibition, $p<0.001$) [Fernandez 1998].

Loganin applied topically (in acetone or 80% aqueous ethanol) at 1 mg/ear inhibited TPA-induced mouse ear oedema by 76.8%. The effect of oral administration at 100 mg/kg b.w. was minimal and short-lived, with maximum activity at 3 hours (n = 6) [Recio 1994].

Oral administration of loganin to type 2 diabetic *db/db* mice (n=6 or 10) at a dose of 100 mg/kg b.w. daily for 8 weeks significantly reduced liver weight ($p<0.01$), hepatic glucose ($p<0.05$), triglycerides ($p<0.01$) and total cholesterol levels ($p<0.01$) compared to control mice receiving vehicle only; 20 mg/kg had no significant effect. Levels of biomarkers (TBARS and ROS) associated with oxidative stress in the liver and kidney were also evaluated. Both 20 and 100 mg/kg loganin significantly reduced TBARS and ROS ($p<0.01$) in liver, while in the kidneys both dose levels reduced ROS ($p<0.01$) but only the higher dose reduced TBARS ($p<0.05$) [[Yamabe 2010].

In a continuation of the experiment the effects on diabetic *db/db* mice receiving loganin (20 or 100 mg/kg b.w./day p.o.) were compared with vehicle-treated *db/db* and non-diabetic *m/m* mice. Administration of loganin at both dose levels led to a reduced food intake (g/day) by *db/db* mice compared to vehicle-only controls ($p<0.05$). With 100 mg/kg b.w. a lowering in serum glucose ($p<0.01$) and an elevation of leptin ($p<0.05$) were observed. Diabetic oxidative stress was significantly up-regulated in the liver of *db/db* mice and loganin (100 mg/kg) administration decreased expressions of hepatic proteins Nox-4 ($p<0.01$) and $p22^{phox}$ ($p<0.05$). Hepatic levels of ROS and TBARS were higher in *db/db* mice in comparison to *m/m* mice. Loganin administration at both dose-levels down-regulated hepatic protein expression of NF-κB, COX-2 and iNOS. At a dose of 100 mg/kg loganin led to a significantly reduced expression ($p<0.05$) of the anti-inflammatory factor Nrf-2 [Park 2011].

Pharmacokinetic properties
No data available for bogbean leaf.

A study using rats (n = 5) examined the tissue distribution of loganin. After a single oral dose of 20 mg/kg b.w. the highest level was found in kidney tissue, followed by stomach, lung and small intestine. Peak levels in most tissues were attained at 90 minutes. No long-term accumulation of loganin was found in rat tissues. The results indicated that the kidney was the major distribution tissue of loganin in rats [Li 2006] and can have a nephroprotective effect [Jiang 2011].

Preclinical safety data

Mutagenicity
Extracts from bogbean leaf have been evaluated in the Ames mutagenicity test using *Salmonella typhimurium* strains TA98 and TA100 (with and without activation by S9 mix). Tinctures

(1:5, ethanol 60% and 70%) and a fluid extract (1:1, ethanol 25%) gave negative results with TA100 and also with TA98 (without activation), but showed weak mutagenicity with TA98 activated by S9 mix. An undefined dry extract showed weak mutagenicity with TA98, both without and with activation [Schimmer 1994].

Clinical safety data
No data available.

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

MILLEFOLII HERBA

2021

Yarrow

DEFINITION

Yarrow consists of the whole or cut, dried flowering tops of *Achillea millefolium* L.s.l. It contains not less than 2 mL/kg of essential oil and not less than 0.02 per cent of proazulenes, expressed as chamazulene ($C_{14}H_{16}$: M_r 184.3), both calculated with reference to the dried drug.

Fresh material may also be used, provided that when dried it complies with the above definition.

Note: The above definition differs slightly from the current monograph for Yarrow/Millefolii herba in the European Pharmacopoeia [Yarrow, Ph. Eur], which defines the botanical source as *Achillea millefolium* L. (without "s.l.", i.e. sensu latiore). Since flowering tops of the hexaploid plant "*Achillea millefolium* L." do not contain proazulenes [Kubelka 1999], a requirement for a minimum content of proazulenes would be unattainable from that particular species.

Various taxa from the *A. millefolium* group are used for medicinal purposes [Jurenitsch 2013]. Extensive pharmacobotanical and phytochemical investigations have led to greater understanding of the *A. millefolium* group and shown that only a few species fulfil the quantitative requirements of the Pharmacopoeia, the most important one being the tetraploid *A. collina* [Saukel 1992a,b; Kubelka 1999; Rauchensteiner 2002].

CONSTITUENTS

The main characteristic constituents (depending on the particular species within the *A. millefolium* group) are:

- Essential oil (0.2-5.9%) containing variable amounts of the main components: α- and β-pinene, 1,8-cineole, sabinene, camphor, borneol, β-caryophyllene and germacrene D [Lawrence 1984, Héthelyi 1989, Hachey 1990, Kokkalou 1992, Figueiredo 1992, Hofmann 1992, Michler 1992, Rohloff 2000, Orth 2000, Rauchensteiner 2002, Benedek 2008, Raal 2012, Chou 2013, Stevanovic 2015, Soltani Howyzeh 2019, Farhadi 2020].

- Sesquiterpenes (appr. 0.5%) [Kastner 1995, Glasl 1999a]:

  Proazulene sesquiterpenes (up to 0.2%) of the guaianolide type [Benedek 2008], which degrade to chamazulene, e.g. 8α-tigloxy-, 8α-angeloxy- and 8α-acetoxy-artabsin, which dominate in *A. asplenifolia* [Kastner 1992, Todorova 2006], *A. roseo-alba* [Kastner 1991], *A. collina* [Schröder 1994, Trendafilova 2006], *A. ceretanica* [Glasl 1999b] and *A. asiatica* [Narantuya 1999, Glasl 2001], but are not present in *A. millefolium* or *A. pannonica* [Kubelka 1999].

  Chamazulene carboxylic acid [Stahl 1954, Imming 2001, Ramadan 2006].

  Non-azulogenic sesquiterpenes of the guaianolide type, e.g. rupicolins [Zitterl-Eglseer 1991], 3-oxa-guaianolides [Schröder 1994], achillinin-type guaianolides [Li 2011, 2012a], 1,10-secoguaianolides [Li 2012b], matricarin derivatives (e.g. achillin, leucodin) [Glasl 2002, Farooq 2012], 1,4-endoperoxides [Rücker 1992, 1994], eudesmanolides [Glasl 1999a, Zhang 2015], longipinanes [Kubelka 1999], germacranes [Kubelka 1999, Ulubelen 1990, Mustakerova 2002, Todorova 2007], achimillic acids [Tozyo 1994].

- Flavonoids (up to 0.8%), mainly flavone- and flavonol-*O*-glycosides, e.g. apigenin 7-*O*-glucoside, luteolin 7-*O*-glucoside, rutin, as well as flavone-*C*-glycosides, e.g. schaftoside and isoschaftoside; polymethoxy derivatives of 6-hydroxy-flavones and -flavonols in leaf exudates [Guédon 1993, Valant-Vetschera 1988, 1994, Kasaj 2001a,b,c, Benedek 2007a; 2008; Benetis 2008].

- Phenolic acids, mainly dicaffeoylquinic acids (DCQA; up to 1.5%) such as 3,5- DCQA (0.3 to 0.8%), 4,5-DCQA, 1,5-DCQA and 3,4-DCQA [Tunón 1994, Benedek 2007a, 2008].

Other constituents include betaines, e.g. stachydrine and betaine [Mehlführer 1997]; amino acids [Goldberg 1969, Petlevski 2002]; protein-carbohydrate complexes [Goldberg 1969]; triterpenes and sterols [Chandler 1982]; tannins [Ivancheva 2000]; thiophenes [Tosi 1991]; carotenoids (mainly lutein) [Kukui 2001]; coumarins (0.35%); polyacetylenes [Teuscher 2016]; tocopherols [Dias 2013]; lignans and terpenoids [Liu 2017]; N-alkylamides [Veryser 2017]; polysaccharides [Freysdottir 2016].

CLINICAL PARTICULARS

Therapeutic indications

Internal use
Loss of appetite; dyspeptic disorders such as mild spasmodic complaints in the abdominal region [Teuscher 2016].

Supportive treatment of spasm associated with dysmenorrhea [Jenabi 2015].

External use
Supportive treatment of small wounds; mild inflammations of the skin and mucous membranes [Jurenitsch 2013, Miranzadeh 2014; 2015, Teuscher 2016, Hajhashemi 2018]; as an insect repellent [Tunón 1994, Thorsell 1998, Jaenson 2006].
In the form of hip baths: spasms of the small pelvis (pelvic congestion) [Jurenitsch 2013, Teuscher 2016].
In these indications, the efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Internal use
Adults: Three to four times daily, 2-4 g of the drug as an infusion; other corresponding preparations [Jurenitsch 2013, Teuscher 2016].

External use
2-4 mL of tincture (1:5, 45% ethanol); 2-4 mL of fluid extract (1:1, 25% ethanol); as a hip bath, 100 g of the drug to 20 litres of water [Jurenitsch 2013].

Elderly: dose as for adults.

Children from 3 to 12 years under medical supervision only: proportion of adult dose according to body weight.

Method of administration
For oral administration and local application.

Duration of administration
No restriction.
If symptoms persist or worsen, medical advice should be sought.

Contra-indications
Known allergy to plants of the Asteraceae family.

Special warnings and special precautions for use
Several cases of yarrow-induced allergic contact dermatitis have been reported [Diepgen 1989, Stingeni 1999, Paulsen 2001].

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available.
In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Several cases of contact allergy have been reported [Diepgen 1989, Paulsen 2001, Compes 2006].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antimicrobial activity
A 95% methanolic extract inhibited 15 different strains of *Helicobacter pylori* with MICs in the range 1.56-100 µg/mL [Mahady 2005].

A lipophilic extract (ether-hexane-methanol 1:1:1, DER approx. 11:1) exhibited bactericidal and fungicidal activity against *Staphylococcus aureus, Escherichia coli, Pseudomonas aeruginosa, Salmonella enteritidis, Aspergillus niger* and *Candida albicans* [Stojanovic 2005].

Extracts from different origin (Sardinia, Portugal) obtained by supercritical CO_2 extraction were tested for their antifungal activities against yeasts, dermatophytes and *Aspergillus* species. The extracts showed the highest activity against dermatophytes such as *Trichophyton rubrum, T. mentagrophytes, Microsporum gypseum* and *Epidermophyton floccosum*, with MIC values ranging from 0.32-1.25 µL/mL [Falconieri 2011].

In a study on cariogenic bacteria, a 50% ethanolic extract demonstrated an MIC value of 12.5 µg/mL for *Lactobacillus rhamnosus* [Kermanshah 2014].

Significant ($p<0.05$) antifungal activity of essential oil from flowers against *Aspergillus nidulans* A757//UT448 was observed at 0.25 and 0.5 µL/mL [de Sant´Anna 2009].

The growth of nine different Gram positive and Gram negative bacteria was inhibited by essential oils from two different locations with MICs between 12.6 and 112 µg/mL. The best effect was observed against *Staphylococcus epidermidis* [Mazandarani 2013].

The essential oil (5 µL/well) of *A. millefolium* subsp. *millefolium* Afan. exhibited activity against 5 different bacteria in the agar well diffusion assay with the best effect against MRSA [Sevindik 2016].

Chamazulene-free oils of yarrow (*A. millefolium* ssp. *millefolium* and *A. millefolium* ssp. *pannonica*) at a concentration of 5% V/V showed antimicrobial activity against *C. albicans, Proteus vulgaris* and *Salmonella typhimurium* [Karamenderes 2002].

Anti-inflammatory activity
A 20% methanolic extract (DER 2.8:1) as well as the flavonoid and the dicaffeoyl-quinic acid fractions thereof inhibited human neutrophil elastase with IC_{50} values of 23, 20 and 72 µg/mL respectively. The activity on matrix metalloproteinase-2 and -9 was insignificant (IC_{50} values between 600 and 900 µg/mL) [Benedek 2007b].

At 50 µg/mL, a hydroethanolic extract (not further specified) moderately inhibited COX-2 and leukotriene biosynthesis [Kopeinig 2010].

A methanolic extract (yield 21%, containing 9.7% flavonoids and 11.8% dicaffeoylquinic acids) at 100 µg/mL significantly ($p<0.05$) attenuated the effect of IL-1β on NFκB activation in human umbilical vein endothelial cells [Dall'Acqua 2011].

Dendritic cells (DCs) matured under addition of an aqueous extract (yield 3%) at 1, 10 or 50 µg/ml secreted significantly ($p<0.05$) less IL-12p40 as compared to DCs matured without extract. Addition of the extract at 50 or 100 µg/mL during maturation significantly ($p<0.05$) increased secretion of IL-10. The ratio of IL-12p40/IL-10 was reduced, while secretion of IL-6 and IL-23 remained unchanged. Co-culture of DCs matured in the presence of the extract with allogeneic CD4+ T cells decreased IL-17 secretion but did not affect IFN-γ and IL-10 secretion by the CD4+ T cells [Jonsdottir 2011].

Lactone fractions from chloroform extracts of *A. asplenifolia*, *A. collina* and *A. distans* at 500 µg/mL caused 98%, 91.6% and 94.5% inhibition, respectively, of the respiratory burst activity of human neutrophils, which was higher than the inhibition by indomethacin of 72.2% [Choudhary 2007].

In LPS-stimulated THP-1 monocytes, a polysaccharide fraction resulted in a dose-dependent significant increase of the secretion of IL-1β, IL-8, IL-10, IL-12p40, IL-23 and TNF-α (all $p<0.001$) at 100 µg/mL. A tendency to an increase was observed for IL-6 and IL-27. In unstimulated THP-1 cells the compounds had no effect on these cytokines. The LPS-induced nuclear concentration of NF-κB in THP-cells was decreased, but IκBα remained unchanged [Freysdottir 2016].

Dilutions of an essential oil from leaves at 1:50, 1:100 and 1:200 moderately stimulated H_2O_2 and TNF-α production in peritoneal macrophages ($p<0.05$) without causing an overproduction of these compounds [Lopes 2005].

In LPS-stimulated RAW 264.7 macrophages, steam-distilled essential oil significantly ($p<0.05$) decreased cellular NO concentration at 20, 40 and 80 µg/mL in a dose-dependent manner. At these doses, superoxide anion production, lipid peroxidation and GSH concentration were reduced as well (all $p<0.05$). The oil protected the macrophages against LPS-induced DNA damage. Decreased activities of SOD, CAT and glutathione peroxidase (GPx) showed that these enzymes were not involved in this effect. In contrast, the down-regulation of iNOS, COX-2, TNF-α, IL-6 and heme oxygenase-1 expression was shown to contribute to the effects [Chou 2013].

A 78% inhibition of LPS-induced NO production in RAW 264.7 macrophages was observed with essential oil at 45 µg/mL [Ladan Moghadam 2017].

Chamazulene demonstrated dose-dependent inhibition of 5-LOX-mediated leukotriene B_4 synthesis in rat peritoneal nucleophilic granulocytes (IC_{50}: 15 µM) and in a cell-free system (IC_{50}: 10 µM). Inhibition of chemical peroxidation of arachidonic acid metabolites in a cell-free peroxidation system was also demonstrated (IC_{50}: 2 µM) [Safayhi 1994].

Chamazulene carboxylic acid inhibited COX-2 by 43.5% at 50 µM, comparable to the effect of the COX-2 inhibitor nimesulide (50% at 50 µM), whereas COX-1 was only minimally inhibited (17.4% at 50 µM) [Ramadan 2006].

Gastrointestinal effects
Bile flow in the isolated perfused rat liver was dose-dependently increased by a fraction containing 48.8% of dicaffeoylquinic acids and 3.4% of luteolin 7-*O*-glucuronide at concentrations of 10-40 mg/L. The choleretic effect was two- to threefold greater than that produced by cynarin ($p<0.01$) [Benedek 2006].

The aqueous fraction from a 50% methanolic extract (yield 7.8%) was tested for contractile activity on isolated gastric antrum strips from mice and humans. The fraction caused a dose-dependent effect with an EC_{50} of 617.5 µg/mL and a maximal contractile effect of 89.2% at 30 mg/mL in the mouse model and of 581.4 µg/mL and 97.7% respectively in the human model. The contractions remained unaffected by tetrodotoxin and hexamethonium, but were abolished by atropine. Choline was shown to be responsible for the effect [Borrelli 2012].

Radical scavenging and antioxidant effects
Infusions of various *Achillea* species protected human erythrocytes and leucocytes against hydrogen peroxide-induced oxidative damage. This was shown by increased CAT, SOD and GPx activities as well as by reduced glutathione content of the cells and a decrease in lipid peroxidation [Konyalioglu 2005].

A macerate (40% ethanol) at 5.5 and 11 µg/mL significantly ($p<0.05$) suppressed H_2O_2 production in isolated rat heart mitochondria as compared to control [Trumbeckaite 2011].

In human gastric epithelial AGS cells, pre-incubation with a 70% ethanolic extract at 100 µg/mL significantly ($p<0.01$) suppressed ROS generation induced by *Helicobacter pylori* infection [Zaidi 2012].

The activity of an 80% ethanolic extract corresponded to 12 g and 11.7 g rosmarinic acid equivalents/L in the ferric reducing antioxidant power assay and in the iron (III) to iron (II) reducing assay respectively [Mekinić 2013].

Chloroform and methanol extracts from aerial parts and inflorescences resulted in IC_{50} values between 2.7 and 3.1 µg/mL in the DPPH assay and between 2.3 and 3.0 µg/mL in the ABTS assay [Bhat 2014].

Lipid peroxidation induced by sodium nitroprusside in mice brain homogenates was determined by the increase of MDA, which was significantly ($p<0.001$) inhibited in a dose-dependent manner by a methanolic and an ethanolic extract at 250, 500 and 1000 µg/mL [Barut 2017].

The EC_{50} values of DPPH scavenging were 43.4 µg/mL for an ethanolic extract and 40.3 µg/mL for a 50% ethanolic extract [García-Risco 2017].

An aqueous and an ethanolic extract inhibited DPPH radicals with IC_{50} values of 20.4 and 18.1 µg/mL respectively [Guz 2019].

Steam-distilled and non-distilled plant material from yarrow was extracted with solvents of different polarity and the resulting fractions were tested for radical scavenging activity (NBT/hypoxanthine superoxide, DPPH$^{\bullet}$ and $^{\bullet}$OH/luminol chemiluminescence methods) and antioxidant activity (β-carotene bleaching test). Most of the fractions had radical

scavenging properties, whereas antioxidant activity of all the extracts was very low or undetectable [Parejo 2002].

In human platelets, a protective effect on proteins against damage induced by peroxynitrite was observed with a purified fraction containing carbohydrates and polyphenols from an alkaline extract (yield 6.6%). The fraction inhibited the tyrosine nitration and reduced the level of carbonyl groups with IC_{50} values of 115 and 100 µg/mL respectively [Saluk-Juszczak 2010].

An ethylacetate fraction prepared from a methanolic extract exhibited radical scavenging effects with 55.1% inhibition at 40 µg/mL, 97% at 20 µg/mL and 85.5% at 100 µg/mL against DPPH, ABTS and superoxide anion radicals respectively. The reduction of lipid peroxidation was 36.6% at 10 µg/mL [Sevindik 2015].

An essential oil (*A. millefolium* subsp. *millefolium* Afan.) strongly reduced the DPPH$^{\bullet}$ radical (IC_{50}: 1.56 µg/mL) and had a hydroxyl radical scavenging effect in the Fe^{3+}-EDTA-H_2O_2 deoxyribose system (IC_{50}: 2.7 µg/mL). It also inhibited non-enzymatic lipid peroxidation of rat liver homogenate (IC_{50}: 13.5 µg/mL) [Candan 2003].

B16 melanoma cells were stimulated with melanocyte stimulating hormone (MSH). The essential oil restored the MSH-induced changes in lipid peroxidation and the levels of superoxide anion, GSH, SOD, CAT and GPx in a dose-dependent manner. The changes were significant ($p<0.05$) for all parameters at 10 and 20 µg/mL [Peng 2014].

An essential oil demonstrated an IC_{50} value of 12.5 µg/mL in the carotene bleaching assay and an EC_{50} of 13 µg/mL in the ferric reducing power assay. Lipid peroxidation was inhibited with an IC_{50} of 78.5 µg/mL [Ladan Moghadam 2017].

Spasmolytic activity
An extract (5.5:1, 70% methanol) inhibited both spontaneous and K^+-induced contractions in isolated rabbit jejunum. Incubation with the extract shifted the concentration-response curves of Ca^{++} to higher concentrations. The effects were comparable to those of verapamil [Yaeesh 2006].

Extracts of different polarity showed dose-dependent relaxant activity on carbachol-induced contractions of rat tracheal rings. The hexane extract was most active (EC_{50}=412.5 µg/mL; positive control theophylline EC_{50}=51 µg/mL) and acted as a non-competitive antagonist on muscarinic receptors. The NO/cGMP pathway contributed to the relaxation of the tracheal smooth muscle and the Ca^{2+} influx blockade into the smooth muscle cells was identified as the most important mechanism. The sesquiterpene lactones leucodin and achillin were shown to be responsible for the observed activities [Arias-Durán 2020].

A flavonoid fraction (10.2% total flavonoids) dose-dependently decreased the force of contractions in isolated guinea-pig ileum. Apigenin and luteolin were much more potent than their respective glycosides. Contractions caused by histamine were significantly ($p<0.05$) decreased by the flavonoid fraction. The spasmolytic effect was caused mainly by inhibition of calcium influx [Lemmens-Gruber 2006].

Oestrogenic effects
A methanolic extract and a fraction thereof showed oestrogenic activity in recombinant MCF-7 cells expressing oestrogen receptor (ER) α and transfected with luciferase transporter gene. The lowest effective concentrations were 8.57×10^{-5} mg/mL and 2.8×10^{-4} mg/mL respectively ($p<0.01$). In a test for α or β ER preference using SK-NBE cells, the maximum activity of the 10% methanolic extract was achieved at 6.19×10^{-5} mg/mL on ER α and 2.48 × 10–4 mg/mL on ER β [Innocenti 2007].

A significant ($p<0.05$) increase in the proliferation of vascular smooth muscle cells was observed with 20 µg/mL of a methanolic extract (yield 21%, containing 9.7% flavonoids and 11.8% dicaffeoylquinic acids). The effect was abolished by the ER antagonist ICI 182.780 [Dall'Acqua 2011].

In a human ER α yeast assay, an essential oil showed antioestrogenic activity and at 0.1 µl/mL reduced the oestradiol-mediated activity by 77.2% [Contini 2020].

Antiproliferative and cytotoxic effects
At 50 µg/mL, chloroform and methanolic extracts from aerial parts and inflorescences showed cytotoxicity against cancer cell lines: THP leukaemia cells were inhibited by 58-99%, PC-3 prostate cancer cells by 20-77%, MCF-7 breast cancer cells by 46-98% and OVCAR-5 ovary cancer cells by 19-99%. The chloroform extracts were more active than the respective methanol extracts [Bhat 2014].

Antiproliferative effects on MIA PaCa-2 human pancreatic cancer cells were shown for an extract obtained by supercritical fluid extraction (SFE; IC_{50}: 31.5 µg/mL) and an ethanolic extract (IC_{50}: 65.0 µg/mL) [García-Risco 2017].

An extract (80% ethanol, not further specified) inhibited the growth of the human cancer lines NCI-H460 (non-small cell lung cancer) and HCT-15 (human colorectal adenocarcinoma) with GI50 values of 187.3 and 70.8 µg/mL respectively. At 100 µg/mL, the extract caused significant ($p<0.05$) reductions in cell viability of 55% and 82% respectively. The extract led to alterations in the cell cycle and increased apoptosis levels in both cell lines. The p53 and p21 expression in NCI-H460 cells (which have wild type p53) increased, while XIAP levels in HCT-15 cells (with mutant p53) were reduced [Pereira 2018].

In a study comparing different extraction methods, a supercritical fluid extract from leaves was most active on MIA PaCa-2 cell viability with an IC_{50} of 31.4 µg/mL and an LC_{50} of 70.6 µg/mL. A significant ($p<0.001$) induction of late apoptosis was observed at 70 and 100 µg/mL of the extract. In a three-dimensional model, the extract at 50 and 70 µg/mL significantly reduced size ($p<0.0001$) and numbers ($p<0.001$) of cancer spheroids. Pretreatment with the extract at 25 µg/mL potentiated the effect of various concentrations of 5-flourouracil ($p<0.05$ to 0.001). The activity against PANC-1 human pancreatic cancer cells was less pronounced [Mouhid 2018].
An additional study showed that this extract significantly ($p<0.05$) downregulated Sterol Regulatory Element Binding Transcription Factor (SREBF1) at 70 µg/mL in MIA PaCa-2 cells. The expression levels of two downstream targets of SREBF1, namely fatty acid synthase and stearoyl-CoA desaturase were significantly inhibited in MIA PaCa-2 and PANC-1 cells ($p<0.001$ to 0.0001) [Mouhid 2019].

The water-soluble fraction from a hydroalcoholic extract had a cytotoxic effect on B16 mouse melanoma cells, inhibiting cell proliferation at 0.05-0.1 mg/mL [Trouillas 2003].

A chloroform fraction from a methanolic extract at 10 µg/mL exerted an 88.9%, 53.9% and 21.4% inhibition of proliferation of HeLa, MCF-7 and A-431 carcinoma cell lines respectively. In an activity-guided approach, centaureidin was isolated as the most active component with IC_{50} values of 0.082 µM for HeLa, 0.125 µM for MCF-7 and 0.354 for A-431 cells [Csupor-Löffler 2009].

Cholinesterase inhibiting effects
A hexane macerate (yield 1.96%) from *A. millefolium* L. subsp. *pannonica* inhibited acetylcholinesterase and butyrylcholinesterase with IC_{50} values of 27.2 and 6.4 µg/mL respectively. An ethanolic macerate (yield 3.8%) showed only butyrylcholinesterase inhibition (IC_{50} 49.6 µg/mL) [Kurt 2018].

An n-butanol fraction from a methanolic extract demonstrated inhibitory activity against acetylcholinesterase (51.3% at 25 µg/mL). The inhibition of butyrylcholinesterase was less pronounced (23.5%) [Sevindik 2015].

Other effects
A 5% m/V hot water infusion significantly ($p<0.001$) shortened recalcification time (a test of blood coagulation) in human plasma to 43% of that of 0.9% sodium chloride. The flowering herb had the highest haemostyptic activity, whereas pressed juice significantly ($p<0.05$ to $p<0.001$) prolonged blood coagulation [Sellerberg 2000].

An ethanolic extract moderately inhibited the human cytochrome P450 enzymes CYP3A4, CYP19 and CYP2C19 by 25%, 43% and 63% respectively [Scott 2006].

An extract (70% ethanol, yield 18%) caused a concentration-dependent inhibition of atrial force and rate in spontaneously beating guinea-pig atrial tissues (EC_{50} 1.4 and 1.5 mg/mL respectively). In isolated rabbit aortic rings, the extract relaxed contractions induced by phenylephrine and K^+ with EC_{50} values of 2.8 and 3.1 mg/mL respectively. In guinea-pig tracheal strips, carbachol- and K^+-induced contractions were inhibited (EC_{50} 2.7 and 2.6 mg/mL respectively) [Khan 2011].

Punch biopsies from full-thickness abdominal skin from a 60-year-old female donor were treated with a water extract (not further specified) for 72 hours. Changes in the expression pattern of three epidermal differentiation markers were visualized by immunostaining. The markers were significantly improved by addition of 0.5% extract to the cultivation medium as shown by the staining intensity: filaggrin from 56.9 to 62.7 ($p<0.05$), cytokeratin 10 from 34.7 to 70.8 ($p<0.001$), transglutaminase-1 from 35.6 to 22.6 ($p<0.001$). A significant difference ($p<0.05$) was also measured in the average depth of staining between control (68.5 µm) and biopsies treated with the extract (52 µm), which was closer to the distribution usually observed in young skin biopsies. As compared to control, a significantly thicker epidermis was observed in treated biopsies (97.9 vs. 86 µm; $p<0.05$) [Pain 2011].

A methanolic extract (not further specified) showed anti-plasmodial activity against the chloroquine-resistant *Plasmodium falciparum* strain W2 with an IC_{50} of 44.6 µg/mL [Vitalini 2011].

In isolated rat heart mitochondria, a macerate (40% ethanol) induced a dose-dependent reduction in State 3 respiration rate without any changes in the integrity of the inner mitochondrial membrane. Under use of pyruvate+malate as substrate this decrease was significant ($p<0.05$) at the highest dose of 33 µg/mL. With succinate as substrate, significant ($p<0.05$) reduction was observed at 11, 22 and 33 µg/mL of the extract. State 2 and State 4 respiration rate remained unchanged upon treatment with the extract [Trumbeckaite 2011].

Pretreatment of 3T3-L1 adipocytes with a 70% ethanolic extract at 100 µg/mL significantly ($p<0.05$) increased PPARγ mRNA relative expression fivefold compared with control. The increase was also approximately fivefold compared to the expression induced by pioglitazone as positive control. The effect correlated with overexpression of GLUT4 (about two-fold; $p<0.05$ with respect to control), resembling the one of pioglitazone. In RINm5F cells, the extract (200 µg/mL) significantly increased insulin secretion and promoted intracellular $[Ca^{2+}]$ rise ($p<0.05$ as compared to control), both to a similar extent as glibenclamide (400 µM) [Chávez-Silva 2018].

Matrix metalloproteinases (MMP)-1, -8 and -13 were inhibited by a methanolic extract at 2, 5, 10, 25 and 50 µg/mL. The inhibition was 67.2 to 81.2% for MMP-1, 72.0-73.5% for MMP-8 and 77.9 to 89.2% for MMP-13 [Gonulalan 2019].

A methanolic extract at 100 µg/mL resulted in a significant ($p<0.0001$) activation of the gene expression mediated by the electrophile response element [Papadi 2019].

MSH-induced melanin production and cellular tyrosinase activity in B16 melanoma cells were significantly ($p<0.05$) reduced by steam-distilled essential oil at 5, 10 and 20 µg/mL. The decrease in melanin production by the oil was regulated by restoration of MHS-induced changes of protein levels of several kinases of the MAPK family [Peng 2014].

In vivo experiments

Anti-inflammatory effects
A dry 80% ethanolic extract, administered orally at 100 mg/kg, inhibited oedema in the carrageenan-induced rat paw oedema test by 29% ($p<0.05$) compared to 45% by indomethacin at 5 mg/kg ($p<0.01$) [Mascolo 1987].

Infusions of *A. aspleniifolia* (diploid, rich in proazulenes) and *A. pratensis* (tetraploid, free from proazulenes) were extracted with dichloromethane and ethyl acetate to yield dry fractions of low (terpenoids), intermediate (flavonoids) and high polarity. When applied topically in the croton oil ear test in mice, the lipophilic fractions and the dry aqueous infusion from *A. asplenifolia* showed higher activity than those from *A. pratensis* [Della Loggia 1992].

In similar experiments with infusions and fractions from *A. asplenifolia*, *A. collina*, *A. x roseoalba*, *A. setacea* and *A. pratensis*, lipophilic fractions of the proazulene-containing taxa showed higher anti-oedematous activity (≥ 50% reduction at concentrations of 270-485 µg/ear) than the proazulene-free taxa [Kastner 1993a]. Several main sesquiterpene lactones of these taxa produced inhibitory effects comparable to that of matricin [Kastner 1993b; Rohloff 2000].

After removal of chloroform-soluble components from yarrow, the water-soluble components were extracted and fractionated for evaluation in the yeast-induced mouse paw oedema test. At 40 mg/kg b.w. various fractions reduced inflammation by 10-35%, compared to 44% and 26% respectively, for the same doses of indomethacin and phenylbutazone [Goldberg 1969].

In another mouse paw oedema test, oral administration of dichloromethane-soluble fractions from an infusion (250 mg/kg) and a decoction (500 mg/kg) (*A. collina*) inhibited inflammation by 21% and 40% respectively [Pavlescu 1995].

A germacrane sesquiterpene from *A. pannonica* dose-dependently inhibited croton oil-induced ear oedema in mice (ID_{50}: 0.40 µmol/cm^2). At a concentration of 0.75 µmol/cm^2 it inhibited the oedematous response to an extent (61%) greater than that of an equimolar dose of indomethacin (43%). Its effect on granulocyte recruitment at the site of inflammation (61% inhibition) was also greater than that of equimolar indomethacin (51%) [Sosa 2001].

In the mouse ear inflammation test, topical application of chamazulene carboxylic acid at 1 µM per ear resulted in 38% inhibition of oedema after 6 hours ($p<0.05$). After oral administration at 300 mg/kg b.w. only 17% inhibition was observed in the carrageenan-induced rat paw oedema test [Ramadan 2006].

Spasmolytic effects
Spasmolytic activity of an ethanolic extract from *A. collina* was demonstrated in mice after oral administration at 500 mg/kg b.w.; it delayed intestinal transit by 43% [Pavlescu 1995].

Gastroprotective effects
Seven days after induction of chronic gastric lesions in rats by acetic acid, a hot water extract (approx. 3:1) was administered orally at 100 or 300 mg/kg/day for 7 days. Compared to controls a significant and dose-dependent healing effect was observed ($p<0.05$, ED_{50}: 32.4 mg/kg). When the same treatment started 1 day after injection of acetic acid, it did not prevent the formation of gastric ulcers. Oral pre-treatment with the extract one hour before induction of acute gastric lesions by ethanol had a dose-dependent protective effect ($p<0.05$, ED_{50}: 936 mg/kg). Gastric lesions induced by indomethacin one hour after subcutaneous administration of the extract were significantly reduced ($p<0.05$) only by 2000 mg/kg [Cavalcanti 2006].

A 90% ethanolic macerate (yield 17.4%) was administered orally to female Wistar rats at 30, 100 and 300 mg/kg one hour before induction of acute gastric lesions with ethanol. The extract at all doses significantly ($p<0.001$) reduced the lesion area by 35%, 56% and 81% respectively. The treatment restored decreased GSH levels (300 mg/kg; $p<0.05$) and SOD activity (all doses; $p<0.05$) in the gastric mucosa. Oral treatment with 1 and 10 mg/kg twice daily for 7 days significantly reduced the volume of gastric ulcers induced by acetic acid by 43% ($p<0.05$) and 65% ($p<0.001$) respectively. In histological analyses, regeneration of the gastric mucosa was observed. GSH levels were restored to baseline ($p<0.001$) at 10 mg/kg, and SOD activity was improved ($p<0.05$ at both doses). Increased myeloperoxidase activity was also decreased by 68% at 10 mg/kg [Potrich 2010].

An aqueous fraction from a 50% methanolic extract (yield 7.8%) dose-dependently stimulated gastric emptying in male Swiss mice at 10 mg/kg i.p. ($p<0.01$ vs. control) and 30 mg/kg i.p. ($p<0.001$) with an EC_{50} value of 6.2 mg/kg. Delayed gastric emptying in cisplatin-treated mice was significantly improved at all doses (1, 3, 10 and 30 mg/kg i.p.; $p<0.01$ to $p<0.001$ compared to cisplatin; EC_{50} 1.6 mg/kg) [Borrelli 2012].

Antidiabetic effects
Streptozotocin-induced diabetic Wistar rats received an extract (80% ethanol, not further specified; 100 mg/kg/d i.p.) for 14 days. The extract improved the decreased body weight and serum insulin as well as increased blood glucose levels in diabetic animals. Serum insulin levels were significantly ($p<0.05$) higher at days 10 and 14 and reached normal values. Blood glucose levels were significantly ($p<0.05$) reduced at days 10 and 14. A significant ($p<0.05$) increase in body weight was observed at the end of the study (day 14). Elevated iNOS and IL-1β expression in pancreatic tissues of diabetic rats were significantly ($p<0.05$) reduced by the extract. No differences between normal control rats and normal rats receiving the extracts were observed in any of the parameters at all time points (days 3, 7, 10 and 14) [Zolghadri 2014].

Normoglycaemic CD1 mice were treated orally with 100 µg/kg b.w. of an extract (70% ethanol; yield 18.6%) 30 min before receiving 2 g/kg glucose in an oral glucose tolerance test. The extract significantly ($p<0.05$) decreased the percentage variation of glycaemia at 0.5 and 1 h as compared to control. In a similar sucrose tolerance test, compared to control the reduction was significant ($p<0.05$) over three hours and slightly better than the positive control acarbose. In mice with streptozotocin (STZ)-induced Type-2 diabetes, the extract at 33, 100 and 330 mg/kg significantly decreased the glucose levels starting at 30 min. This reduction sustained for 7 h ($p<0.05$ for all doses at all time points compared to control) and was similar to glibenclamide (3 mg/kg) as positive control [Chávez-Silva 2018].

An aqueous dry extract (1:10) was administered orally at doses of 10, 30, 90 and 270 mg/kg b.w. to STZ-induced diabetic Balb/c mice for 20 days. Increased fasting blood glucose levels after STZ were significantly ($p<0.05$) reduced at days 7, 13 and 20, with the two highest doses being more effective than glibenclamide. The same effects were observed for creatinine and urea levels, where the two highest concentrations restored the levels to normal control. Decreased red blood cell parameters were significantly ($p<0.05$) improved by all treatments. Increased platelets and white blood cell counts in STZ mice were significantly ($p<0.05$) reduced by all extract doses. The improvements in red and white blood cell counts reached normal values with the two highest doses. Histopathological signs of renal hypertrophy were ameliorated by the extract [Zangeneh 2018].

Streptozotocin-induced diabetic rats were treated with an extract (70% ethanol, not further specified; 25 and 100 mg/kg b.w./day p.o.) for 28 days. The extract at both doses alleviated the decreased body weight gain of diabetic rats. Significant dose-dependent improvements of the increased levels of fasting blood glucose, AST, ALT, LDL-, total cholesterol and triglycerides were observed ($p<0.001$ to $p<0.013$). The reduced HDL levels in diabetic rats were elevated significantly at both doses ($p<0.05$ and $p<0.006$, respectively). All effects of the higher dose were comparable to 250 mg/kg/day metformin as positive control [Rezaei 2020].

Hepatoprotective effects
The anti-hepatotoxic activity of dry extracts of varying polarity was evaluated in rats treated with carbon tetrachloride or paracetamol. Liver function was assessed by the levels of ALT and AST. Intraperitoneal administration of the extracts at 50 mg/kg reduced ALT/AST levels by 50-96% in carbon tetrachloride-treated animals and 41-91% in paracetamol-treated animals ($p<0.05$) [Graf 1995].

An extract (5.5:1, 70% methanol) at 150, 300 and 600 mg/kg b.w. i.p. exerted a protective effect against D-galactosamine + LPS-induced hepatitis in mice, significantly ($p<0.05$) and dose-dependently reducing plasma ALT and AST levels in treated animals compared to controls. Assessment of liver histopathology revealed an absence of congestion and focal necrosis in treated animals, with a dose-dependent improvement in cellular swelling and the number of apoptotic cells. Pre-treatment with the extract reduced mortality from 100% to 40% [Yaeesh 2006].

Effects on blood pressure
Intravenous administration of an extract (70% ethanol, yield 18%) to normotensive rats under anaesthesia at 1, 3, 10, 30 and 100 mg/kg b.w. caused a dose-dependent decrease of mean arterial blood pressure (MAP) between 8.3 and 45.0% [Khan 2011].

A 90% ethanolic extract (yield 17.39%) was administered orally to male Wistar rats at various time points before the measurement of MAP. At 3 hours after administration of 100 and 300 mg/kg, significant reductions (13 and 14 mm Hg respectively; $p<0.01$) in MAP were observed. The dichloromethane fraction from this extract at 20 mg/kg led to a reduction of 10 mm Hg at the same

time point. Artemetin, as a major compound in this fraction, dose-dependently decreased MAP by up to 11.5 mm Hg at 1.5 mg/kg i.v. At 0.75 mg/kg i.v. it significantly ($p<0.01$) reduced the hypertensive response to angiotensin I whereas it increased the average duration of bradykinin-induced hypotension. The compound (1.5 mg/kg p.o.) decreased plasma angiotensin converting enzyme (ACE) by about 37% and vascular ACE by up to 63% as compared to control [de Souza 2011].

Other effects

Addition of 0.5%, 1% and 1.5% yarrow to the diet of broilers resulted in significantly better feed conversion rates ($p<0.01$ compared to control). No significant differences were observed in the final body weight. The gastrointestinal tract weight, relative to body weight, significantly ($p<0.01$) increased [Norouzi 2015].

No changes were observed in relative uterus weights of immature female rats after oral administration of an aqueous extract (1:2.5) at 0.6 and 1.2 g/kg daily for 3 days in comparison with vehicle-treated animals. In oestrogen-treated rats the extract (1.2 g/kg/day p.o.) was unable to block the uterotrophic action [Dalsenter 2004].

A decoction (corresponding to 6 to 12 mg drug/kg i.p.) was administered to female Wistar rats during late proestrus or diestrus. Doses of 8, 10 or 12 mg/kg reduced conflict behaviour during late proestrus ($p<0.05$ at all doses). During diestrus, 12 mg/kg showed a significant reduction of conflict behaviour ($p<0.05$) [Molina-Hernandez 2004].

Cutaneous lesions were induced in female Balb/c mice by intradermal injection of *Leishmania major* promastigotes. Topical treatment with an extract (80% ethanol, not further specified) twice daily for 6 weeks started 35 days after infection. A control group received meglumine antimoniate (0.02 mL/g i.p. once daily for 20 days). The mean ulcer size at the end of the study was significantly ($p<0.006$) reduced by 43.3% with the extract when compared to the control group that exhibited a 22.6% increase in ulcer size [Nilforoushzadeh 2008].

A hydroalcoholic extract (not further specified) was evaluated for antinociceptive effects in male Swiss mice. In animals treated orally with 500 and 1000 mg/kg b.w. significant ($p<0.001$) inhibition of abdominal contortions, by 65% and 23% respectively, was observed in the writhing test. No activity of the extract was seen in the hot plate test or in immediate or late responses in the formalin test. Motor activity, motor coordination and intestinal transit of charcoal remained unchanged [Pires 2009].

An extract (90% ethanol, yield 17.4%) was tested for anxiolytic effects in male albino Swiss mice. In the elevated plus-maze test, the extract at single oral doses of 300 or 600 mg/kg resulted in significantly longer time spent in the open arms and a higher number of entries into the open arms ($p<0.05$ to $p<0.01$ as compared to vehicle). The effects were slightly stronger than those of 0.75 mg/kg diazepam. Doses of 30 and 100 mg/kg remained without effect. After treatment for 25 days similar effects were observed ($p<0.01$ to $p<0.001$). In the marble-burying test acute ($p<0.05$) and chronic treatment ($p<0.01$ and $p<0.001$) at all doses reduced the number of marbles buried compared to the vehicle group. Neither treatment regimen demonstrated any effect in locomotor activity in the elevated maze assay. The extract did not induce changes in [3H]-flunitrazepam binding [Baretta 2012].

Male NMARI mice received an aqueous extract (not further specified) at doses of 50, 250, 500 or 1000 mg/kg i.p. daily for 20 days. The treatment did not affect activity levels in the novel object recognition test. The extract did not decrease body weight or cause death [Ayoobi 2013].

Wistar rats received an infusion (35 g fresh leaves/L) at 1 mL/100 g via gavage 2 hours before, simultaneously or 2 hours after i.p. administration of cyclophosphamide. Chromosome aberrations induced by cyclophosphamide were reduced by 68.1% by pretreatment with the extract, by 68.5% under simultaneous administration and by 67.1% with post-treatment [Düsman 2013].

The diuretic activity of extracts and fractions and the underlying mechanisms of activity were evaluated in male Wistar rats. An aqueous extract (AEAM) at 125, 250 and 500 mg/kg, a 90% ethanolic extract (HEAM, yield 17.4%) at 30, 100 and 300 mg/kg as well as a dichloromethane subfraction (DCM) at 10 and 30 mg/kg were administered orally, hydrochlorothiazide (HCTZ; 10 mg/kg) served as a positive control. Conductivity, pH and density of the urine remained unchanged with all treatments. AEAM did not affect urinary volume or electrolyte excretion. Similar to HCTZ, increased diuresis was observed with HEAM at 300 mg/kg from 4 to 8 hours (between 30 and 60%; $p<0.05$ to 0.001) and with DCM at 30 mg/kg at 8 hours ($p<0.01$) as compared to control (vehicle only). Both treatments increased the excretion of Na^+ and K^+. The diuretic effect of DCM was abolished by the bradykinin B2 receptor antagonist HOE-140 and by indomethacin, a COX inhibitor ($p<0.001$) [de Souza 2013].

In male Wistar rats, urolithiasis was induced by ethylene glycol (EG) for 30 days. An 80% ethanolic extract (not further specified) was administered orally from day 15 until day 30 at 200 mg/kg (group C) and 400 mg/kg (group D). Group E was treated with the extract at 200 mg/kg from day 1 to day 30. Group A received tap water and group B EG only. At day 30, the increased urinary oxalate concentration found in group B was significantly reduced in groups C and D ($p<0.04$) and in group E ($p<0.02$ compared to groups C and D). The improvement of the decreased urinary citrate concentration after EG was significant in groups D and E ($p<0.03$ and 0.015 respectively, compared to group B). The mean number of calcium oxalate deposits was significantly higher in all EG-treated groups ($p<0.05$ as compared to group A) and was above 40 in group B only. Treatment with the extract resulted in a significant reduction to 20.1 ($p<0.001$, group C), 16.4 ($p<0.01$, group D) and 14.3 ($p<0.004$, group E) as compared to group B [Bafrani 2014].

An aqueous extract (not further specified) was administered to male C57BL/6 mice 24 hours after induction of experimental autoimmune encephalomyelitis (EAE) at 40, 200 and 400 mg/kg daily for 21 days. Behavioural disabilities were determined by a score system for different stages of paralysis and started in the EAE group on day 13.2 with the maximum score of 3.4 on day 17 after induction. In the groups receiving the low or the high dose of the extract, first disabilities were seen on day 18 and day 17, respectively, with significantly lower scores compared to the EAE group ($p<0.014$ and $p<0.021$). With the medium dose, no disabilities were observed until day 21. The body weight was significantly decreased in EAE on day 21 as compared to day 1 ($p<0.003$), but unchanged in any other group. In the brain, the extract caused decreases of demyelinated lesions at all doses and of inflammatory cells with the two higher doses ($p<0.013$ and 0.01). Decreased serum levels of the cytokine TGF-β in EAE were improved with the extract, significant ($p<0.026$) at the highest dose [Vazirinejad 2014].

The mean daily energy intake of male Wistar rats was recorded over ten days. The animals then received a 70% methanolic extract at 50 mg/kg (group 1), 100 mg/kg (group 2) and 150 mg/kg (group 3) daily for 7 days by gavage. In groups 1 and

2 the mean energy intake significantly ($p<0.001$) increased as compared to that during the observation period. In contrast, in group 3 the intake decreased significantly ($p<0.001$). The total energy intake during 24 hrs after extract administration at doses of 50 and 100 mg/kg also displayed a significant ($p<0.05$) increase compared to control. In a second experiment, no significant changes of plasma ghrelin levels were measured at 0, 0.5, 1, 2 and 4 hours after administration of 100 mg/kg extract [Nematy 2017].

Male Wistar rats were treated for 48 days with nicotine alone (0.2 and 0.4 mg/kg/day i.p.) or combined with oral administration of an extract (70% methanol, not further specified, 120 mg/kg/day). The decreased sperm count and motility as well as the percentage of immature sperm following nicotine administration were improved by the extract. The percentage of dead sperm after high dose nicotine (HNic) was diminished significantly ($p<0.05$). In the serum, the extract reduced the adverse effects of HNic on FSH, LH and testosterone concentrations and on SOD levels. LDH levels were significantly ($p<0.05$) decreased by the extract as compared to both nicotine groups and control. Total NO and MDA in testes tissues were improved with the extract. The tubule differentiation index as well as oedema and atrophy in seminiferous tubules after nicotine were almost restored to control, and other histological parameters were improved by the extract [Hallaj Salahipour 2017].

In a very similar experiment with widely consistent results, the extract also significantly ($p<0.05$) reduced the increased epididymal sperm apoptosis after nicotine. In this study the extract alone was administered as well and did not cause changes in any of the measured parameters as compared to control [Hasanzadeh Khosh 2017].

In a xenocraft model, male athymic Nude-Foxn1nu mice were subcutaneously injected with MIA PaCa-2 cells. After 15 days at an average tumour volume of 100 mm^3, intragastric treatment with a supercritical fluid extract (1 g/kg 3 times per week for 15 days) started. A significant reduction in tumour growth compared to control was observed from day 10 ($p<0.05$ to $p<0.001$). At the end of the study, tumour weight was significantly ($p<0.05$) lower and tumour volume decreased by 28.7%. No differences were seen in body or liver weights. The number of Ki-67 positive cells and the expression levels of SREBF1 in the tumours of mice treated with the extract decreased compared to control, indicating a reduction in proliferation of tumour cells [Mouhid 2019].

Fractions from an ethanolic extract and several constituents of the extract showed repelling properties against the mosquito *Aedes aegypti*. A solution or suspension of each test substance in 70% ethanol was applied to 42 cm2 of the test person's skin. All fractions of the extract as well as stachydrine and homostachydrine, caffeic, chlorogenic and salicylic acids, pyrocatechol and other compounds had distance- and contact-repelling effects comparable to that of *N,N*-diethyl-*m*-toluamide (DEET). Mixtures of effective single substances showed additive effects [Tunón 1994, Thorsell 1998].

Pharmacological studies in humans

A randomized, double-blind, placebo-controlled trial was performed in women (n=20; 47 to 68 years) with skin phototype I to III. After browning of the skin with dihydroxy-acetone on four areas on the forearm, treatment started twice daily for seven consecutive days with I) a water-in-oil preparation (pH 5.5; placebo), II) placebo with addition of 2% extract (pH 5.5; not further specified), III) placebo with addition of 3% glycolic acid (pH 3.5; positive control), IV) no treatment (negative control). The mean epidermal turnover time was 19.5 ± 14.4 days for the negative control, 16.4 ± 13.9 days for the placebo, 12.9 ± 6.1 days for the extract and 12.3 ± 4.3 days for glycolic acid.

In a second randomized, double-blind, placebo-controlled, split-face trial with the same preparations, 63 women aged 48–67 with crow's feet grade 3 to 6 were enrolled for a treatment twice daily for 56 days. Group 1 applied the preparation with 2% extract to one half of the face and the preparation with 3% glycolic acid to the other side. Group 2 used the preparation with 2% extract and placebo on the two halves of the face respectively. In group 1, the wrinkle grade with the extract was significantly reduced by 14% and with glycolic acid by 12% as compared to baseline (both $p<0.001$). In group 2, wrinkle grade decreased with the extract compared to baseline and to placebo ($p<0.01$ and 0.05 respectively). A reduction in pore appearance (21% with the extract, 19% with glycolic acid) was observed in group 1 (both $p<0.001$, compared to baseline). In group 2 the same reduction was seen, also significant compared to placebo ($p<0.05$). Skin softness was significantly improved in group 1 by 31% with the extract and by 28% with glycolic acid (both $p<0.001$) and in group 2 by 24% compared with baseline ($p<0.001$) and by 19% compared with placebo [Pain 2011].

Four different extracts (DER 1:5) were prepared: I) by maceration of yarrow with 96% ethanol followed by addition of olive oil or sunflower oil under removal of ethanol (E1 and E2) or II) by maceration with olive oil or sunflower oil (E3 and E4). In a double-blind study in 23 volunteers, skin irritation was induced by treatment of the forearm with 8% sodium lauryl sulphate. The participants applied the preparations twice daily for 7 days on specified areas of the irritated skin. The decrease in skin hydration after irritation was improved to basal values by E3 and E4 after 3 days, and with E1 and E2 it took 7 days. The lauryl sulphate-induced increase in skin surface pH was restored to basal values by all preparations after 3 days and after 7 days. A significant ($p<0.05$) improvement compared to untreated irritated skin was observed with E3 and E4. The erythema index (EI) as a measure of skin surface inflammation significantly declined with E1 and E2 after 3 days ($p<0.05$ as compared to untreated, irritated skin). E3 and E4 improved the EI after 7 days [Tadić 2017].

In a field experiment, an extract (ethylacetate, DER 1:4) showed a significant repellent effect ($p<0.03$) against various mosquitos [Jaenson 2006].

Clinical studies

Thirty-one patients with chronic kidney disease were included in a randomized, placebo-controlled trial and received either 1.5 g of powdered yarrow flowers 3 days a week for 2 months (n=16) or placebo (n=15). At the end of the study, plasma levels of nitrite and nitrate were decreased in the verum group from 0.82 ± 0.51 µmol/L to 0.63 ± 0.42 µmol/L and 50.55 ± 17.92 µmol/L to 44.09 ± 17.49 µmol/L respectively, but increased in the placebo group [Vahid 2012].

In a randomized, double-blind, controlled study, cancer patients with chemotherapy-induced oral mucositis (OM; n=56) gargled four times daily for 14 days with either 15 mL of a solution (1.4 g lidocaine, 224 mg dexamethasone, 35g sucralfate/L diphenhydramine solution; control) or a 50/50 mixture of this solution combined with a distillate (for 20 L distillate, 10 kg of yarrow flowers were boiled with 50 L water). The severity of OM was assessed three times before and at days 7 and 14 after the intervention. The mean severity score of OM was 2.39 ± 0.875 in both groups at the start of the study. In the yarrow group, severity was significantly ($p<0.001$) decreased to 1.07 ± 0.85 and 0.32 ± 0.54 at days 7 and 14 respectively. In contrast, the severity significantly ($p<0.001$) increased to 2.75 ± 0.87 and 2.89 ± 0.956 respectively in the control group [Miranzadeh 2014; 2015].

A randomized, double-blind, placebo-controlled study assessed the effectiveness of a tea (4 g/300 mL water three times daily) on the relief of primary dysmenorrhea in women aged 19 to 23 years. The participants took verum (n=45) or placebo (n=46; teabags contained starch) for 3 days from the first menstrual day to the third menstrual day, for 2 cycles, and rated the severity of their menstrual pain using a VAS. The mean change in pain score was significantly greater after verum as compared to placebo after 1 month ($p<0.001$) and after 2 months ($p<0.0001$) [Jenabi 2015].

The efficacy of an ointment containing 5% of a dried extract (90% ethanol) on episiotomy wound healing was studied in primiparous women (n=35) in a randomized, double-blind, controlled trial. Control groups received either no treatment (n=35) or a placebo ointment (n=35). The ointments were applied to the episiotomy wound twice a day for 10 days from day 2 after delivery. The healing process (redness, ecchymosis, oedema, discharge and wound dehiscence) as well as the pain level (assessed by a VAS) were investigated on days 7, 10 and 14 after delivery. A significant improvement in pain level was observed on day 7 when treatment was compared with no intervention ($p<0.05$) and on day 10 when compared to placebo and no intervention ($p<0.05$ and $p<0.01$ respectively). Significant ($p<0.05$) differences between the groups were seen in reduction of redness at days 7, 10 and 14, and of ecchymosis at days 7 and 10. Oedema was significantly ($p<0.05$) reduced on days 7 and 10 as compared to no intervention [Hajhashemi 2018].

In a triple-blind, randomized, placebo-controlled study, 75 patients with multiple sclerosis received either a dried aqueous extract (250 mg corresponding to 2 g drug or 500 mg corresponding to 4 g per day) or placebo for one year as add-on therapy. As compared with placebo, the annualized mean relapse rate was significantly lower ($p=0.003$ for 250 mg and $p=0.013$ for 500 mg), the time to a first relapse significantly longer ($p=0.013$ for 250 mg and $p=0.039$ for 500 mg), and the paced auditory serial addition task was significantly increased ($p=0.025$ and $p=0.009$ for 250 and 500 mg respectively). In the group receiving the higher dose, the changes from baseline to 12 months of the expanded disability status scale, of the multiple sclerosis functional composite and of the volume of T2 lesions were significantly better ($p=0.001$, 0.003 and 0.004 respectively) than placebo. The mean score of Word-pair learning test decreased ($p=0.037$) after 1 year compared to placebo. A significant decrease in depression was observed ($p=0.033$ at month 6 and $p=0.046$ at month 12) after the lower dose [Ayoobi 2019].

Pharmacokinetic properties

Proazulenic sequiterpene lactones, such as matricin and others, have been shown to be precursors of chamazulene carboxylic acid. When matricin was taken by 3 healthy volunteers as a single oral dose of 500 mg in aqueous suspension, plasma concentrations of chamazulene carboxylic acid, determined 75-90 minutes after ingestion, ranged from 0.9 to 2.2 µg/mL [Ramadan 2006].

Preclinical safety data

Single dose toxicity

Yarrow dry extracts of varying polarity (chloroform, methanol or water) were non-toxic in mice; the intraperitoneal LD_{50} was determined as 1.5 g/kg b.w. [Graf 1995].

According to a safety assessment for its use in cosmetics, the oral and subcutaneous LD_{50} values in mice of a yarrow extract (2% yarrow in propylene glycol and water) were both determined as 1 g/kg b.w. Alcoholic extracts of dried leaves and stalks of yarrow did not produce a phototoxic response [Anonymus 2001].

Single doses of a hot water extract (approx. 3:1) at up to 10 g/kg orally or 3 g/kg b.w. i.p. did not cause deaths, changes in behaviour or manifestations of toxic symptoms in Wistar rats over the observation period of 14 days [Cavalcanti 2006].

After i.p. treatment of mice with an extract (5.5:1, methanol 70%) at 3 g/kg b.w. no changes in behaviour were apparent during a 6-hour observation period and there was no mortality after 24 hours [Yaeesh 2006].

No signs of toxicity were observed in male Swiss mice following administration of a hydroalcoholic extract (not further specified) at i.p. doses of 1 and 10 mg/kg and oral doses of 10, 100, 500 and 1000 mg/kg. After an i.p. dose of 100 mg/kg, abdominal contortion without any other signs occurred [Pires 2009].

Strong sensitizing effects in guinea pigs were found to be caused by the sesquiterpene alpha-peroxyachifolide due to the presence of an alpha-methylene-lactone group [Hausen 1991, Rücker 1991].

Repeated dose toxicity

Oral treatment of rats with a hot water extract (approx. 3:1) at 0.3, 0.6 or 1.2 g/kg/day for 28 and 90 days did not result in differences in mobility, reflexes, muscular tonus, breathing patterns or gain in body weight or organ weight compared to control animals, with the exception of a decrease in liver weight in female animals at 0.3 g/kg for 90 days and in male animals at 0.6 g/kg for 28 days and 1.2 g/kg for 28 and 90 days. Histopathological evaluation did not reveal any changes in the stomach, jejunum, ileum, colon, liver, pancreas, adrenals, lung, spleen or kidneys. Slight changes in serum biochemistry were observed, e.g. in cholesterol, HDL-cholesterol and glucose, but were not correlated with dose or time of exposure. Changes in haematological parameters were found only in female rats after 90 days of treatment and were restricted to lymphocyte and neutrophil numbers [Cavalcanti 2006].

An extract (70% ethanol, not further specified) was administered orally to Sprague-Dawley rats at 25 or 100 mg/kg/day for 28 days. No differences in body weight gain, fasting blood glucose, ALT, AST, LDL-, HDL- and total cholesterol as well as triglycerides were observed as compared to saline treated control [Rezaei 2020].

Reproductive toxicity

A liquid extract of aerial parts excluding flowers (1:2, ethanol 45%, corresponding to 500 mg of crude drug per mL) was administered orally to female rats (n=5) at a dose level corresponding to 2.8 g of crude drug per kg b.w. daily (i.e. 56 times the human dose) on either gestation days (GD) 1-8 or 8-15. Control groups were treated with water or the amount of ethanol in the extract. From evaluation performed on GD 20 the dosage used was not materno-toxic. No significant differences were observed between groups in pre- or post-implantation losses. Compared to those of water control animals, placental weights were significantly higher in both yarrow-treated groups (GD 1-8, $p<0.05$; GD 8-15, $p<0.01$) without any histological signs of pathology, while foetal weights were significantly ($p<0.01$) lower in the yarrow GD 8-15 group. No significant differences were observed in the incidence of external or internal malformations [Boswell-Ruys 2003].

Following oral administration of an aqueous extract (1:2.5) from yarrow leaf to male Wistar rats at 0.3, 0.6 and 1.2 g/kg b.w. daily for 90 days, no significant differences in weights of

testis, epididymis, prostate or seminal vesicles were observed compared to controls. Daily sperm production, sperm number and sperm transit rate also remained unaffected. At the highest dose, the percentage of abnormal sperm was significantly higher than in control animals (3.1 versus 1.6%; $p<0.05$) but remained within the expected range (up to 5%) [Dalsenter 2004].

An aqueous extract (1:10) was added at 1.0, 5.0 and 10.0 mL to 100 mL of standard Drosophila medium used for the development of F1 eggs from Oregon-R strain of *Drosophila melanogaster.* After emergence of the flies, no significant changes in the number of offspring or the percentage of malformations were observed as compared to control [Uysal 2007].

Male albino Wistar rats received an ethanolic extract (1:10) for 22 days at 200, 400 or 800 mg/kg daily, i.p or orally. No changes in body and testis weight gain or in behaviour were observed. The doses of 200 mg/kg i.p. and 200 and 400 mg/kg p.o. did not cause significant histological differences of the testes. After 400 mg/kg i.p. scattered immature cells on the basal membrane and a decrease in cell accumulation and vacuolization in seminiferous tubules was observed. Administration of 800 mg/kg i.p. resulted in thickened seminiferous tubules on the basal membrane, decreased cell accumulation in seminiferous tubules, distinct disarrangement, degenerative cells and a strong decrease in sperm count.

After the oral dose of 800 mg/kg/day, the basal membrane was partially thickened and disarrangement of cells was observed. After 40-days of recovery, normal physiology was restored in the group which had received 400 mg/kg i.p. compared to control. The changes induced by 800 mg/kg were not reversed [Takzare 2010].

Mutagenicity

In an early study, a tea (20 g/100 mL) showed weak mutagenic effects in the Drosophila wing spot assay [Graf 1994].

An infusion at a concentration equivalent to 0.35 mg drug/mL of culture medium did not cause clastogenic effects in human lymphocytes. However, after pretreatment of the cells with the alkylating agent mitomycin C the infusion significantly increased the number of chromatid and isochromatid breaks compared to controls treated with mitomycin C only [Roncada 2004].

In the Ames test an aqueous extract (0.06-5 mL) was not mutagenic with or without metabolic activation in *Salmonella typhimurium* strains TA98, TA100, TA102, TA1535 and TA1537 [Vivotecnia Research SL 2009; cited according to Becker 2016].

In 2 micronucleus tests in V79 cells, an aqueous extract (up to 15,000 mg/mL) was not clastogenic or aneugenic with or without metabolic activation [Anonymus 2012; cited according to Becker 2016].

A dried aqueous extract (DER: 6-9:1) did not show any mutagenic effect at concentrations from 70, 221, 700, 2212, 7000 and 8536 µg/plate in the same *Salmonella typhimurium* strains with or without metabolic activation in an incorporation test or a preincubation test [LPT report 2015].

The protective effect of a methanolic extract (not further specified) against radiation-induced genotoxicity was investigated in human lymphocytes. Blood samples from volunteers were incubated with the extract at 10, 50, 100, and 200 µg/mL for 2 hours before exposure to 2.5 Gy X-ray radiation. Then lymphocytes were cultured under mitogenic stimulation. The extract resulted in a significant ($p<0.01$) decrease in the incidence of micronuclei in binucleated cells compared with untreated, irradiated lymphocytes by 49%, 66%, 79% and 86%, respectively. The extract at 200 µg/mL did not exhibit genotoxicity in non-irradiated lymphocytes and the frequency of micronuclei was lower than in the control ($p<0.01$) [Shahani 2015].

An essential oil from flowers at 0.19 and 0.25 µL/mL increased the number of diploid segregants of *Aspergillus nidulans* A757// UT448 in a dose dependent manner. The mitotic segregation index raised significantly ($p<0.05$) from 1.0 in control to 2.0 and 3.7 respectively [de Sant´Anna 2009].

In phytohaemagglutinin-stimulated human peripheral lymphocytes, treatment with an an essential oil for 3 and 48 hours resulted in a dose-dependent, significant ($p<0.01$) decrease in the proliferation index. The effect was less pronounced in the short-term treatment with and without metabolic activation. The presence of micronuclei in mononucleated and binucleated cells increased dose-dependently in both assays, significant only in binucleated cells at dosages above 0.1 µl/mL [Contini 2020].

Clinical safety data

Product formulations containing 0.002% to 0.01% of yarrow extract were generally not irritating. A formulation containing 0.1% of an extract (2% in propylene glycol and water) was not a sensitizer in a maximization test, and alcoholic extracts of dried leaves and stalks did not produce a phototoxic response [Anonymus 2001].

One case of occupational asthma attributed to yarrow has been reported in a 44-year-old woman. The patient began to experience rhinitis, asthma und urticaria symptoms in the workplace when handling dried flowers. Skin prick tests with aqueous extracts from dried flowers of *A. millefolium* gave positive results and a Specific Inhalation Bronchial Challenge with an aqueous extract (1.25 mg/mL) elicited an asthmatic response with a fall in FEV_1 of 31%. Specific IgE (EAST) was 0.9 kU7l and immunoblotting revealed several IgE binding bands of 51, 21 and 18 kDa. The data strongly suggested that an IgE-mediated immunologic mechanism was responsible for the patient's symptoms [Compes 2006].

In a patch test involving 20 patients with known contact allergy to sesquiterpene lactones, two aqueous extracts (residue of 1.5 g drug/50 mL boiling water dissolved in 1 mL water = 100%) caused positive reactions in 8 and 11 participants respectively. Eighteen reactions were observed with the 100% solution, 4 with a 10% dilution and 1 with a 1% dilution. Only one reaction was strong, 3 were weak and all others medium. As compared to chamomile, goldenrod, wormwood and dandelion teas tested in parallel, yarrow resulted in the largest number of late reactions with 3 cases occurring on day 7 and another 3 cases on day 10 [Lundh 2006].

A study performed for the chemical validation of an Asteraceae mix used for patch tests included a yarrow extract among the 5 tested extracts. The data were cross-validated with those of patch tests in 1,778 patients, of which 125 had reacted positively to one of the applied Asteraceae extracts. A positive reaction against yarrow was observed in 28% of the 125 sesquiterpene-sensitive patients [Salapovic 2013].

No significant side effects or adverse events were observed in 75 patients with multiple sclerosis who received a dried aqueous extract (250 mg corresponding to 2 g drug or 500 mg corresponding to 4 g per day) for one year [Ayoobi 2019].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

MYRRHA

Myrrh

2014

DEFINITION

Myrrh consists of a gum-resin, hardened in air, obtained by incision or produced by spontaneous exudation from the stem and branches of *Commiphora molmol* Engler and/or other species of *Commiphora*.

The material complies with the monograph of the European Pharmacopoeia [Myrrh].

Species other than *Commiphora molmol* Engler [synonym: *C. myrrha* (Nees) Engler var. *molmol*] which may be acceptable sources of medicinal myrrh include *Commiphora abyssinica* (Berg) Engler and *C. schimperi* (Berg) Engler [Wichtl 1999].

CONSTITUENTS

Myrrh contains three major groups of compounds: volatile oil (2-10%), resin (25-40%) and gum (30-60%) [Wiendl 1994].

The main constituents of the volatile oil are furanosesquiterpenes of various structural types including furanoeudesma-1,3-diene (principal component), furanoeudesma-1,4-diene-6-one, lindestrene, curzerenone, furanodiene, 2-methoxyfuranodiene and 4,5-dihydrofuranodiene-6-one, together with sesquiterpenes such as α-copaene, elemene and bourbonene [Brieskorn 1982, Brieskorn 1983, Martinetz 1988, Hänsel 1992].

Characteristic constituents of the resin are α-, β- and γ-commiphoric acids, α- and β-heerabomyrrhols, heeraboresene and burseracin [7, 8]; also various terpenes [Mincione 1972;Zhu 2001;Shen 2009;Su 2009;Xu 2011a; Xu 2011b] and a sesquiterpene lactone, commiferin [Mincione 1972].

The water soluble gum is composed of a heterodisperse mixture of proteoglycans in which chains of alternating galactose and 4-*O*-methylglucuronic acid, and separate chains of arabinose, are attached to the protein moieties via hydroxyproline linkages [Wiendl 1994, Hough 1952, Jones 1955].

CLINICAL PARTICULARS

Therapeutic indications

Topical treatment of gingivitis, stomatitis (aphthous ulcers), minor skin inflammations, minor wounds and abrasions; supportive treatment for pharyngitis, tonsillitis [Moeck 2007, Martinetz 1989, Bradley 1992, Hiller 2009, Sweetman 2011, Barnes 2007].

Posology and method of administration

Dosage

Adults: As a gargle or mouthwash, 1-5 ml of tincture (1:5, ethanol 90% V/V) in a glass of water several times daily [Hager, Bradley 1992, Barnes 2007]. For use on skin, dab 2-3 times daily with diluted or undiluted tincture (1:5, ethanol 90% V/V) [Moeck 2007, Bradley 1992, Hiller 2009, Sweetman 2011, Martinetz 1989].

Elderly: as for adults.

Children: as for adults except using only diluted tincture on skin.

Method of administration
For topical application.

Duration of use
No restriction.

E/S/C/O/P MONOGRAPHS

Contra-indications
None known.

Special warnings and special precautions for use
None required.

Because of the alcohol content, a transient burning sensation on the skin may be experienced depending on the level of dilution of the tincture.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice the product should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Very rare cases of allergic contact dermatitis have been reported [Gallo 1999, Al-Suwaidan 1997].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antibacterial and antifungal effects
Various sesquiterpene-containing fractions from myrrh inhibited *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Escherichia coli* and *Candida albicans* with minimum inhibitory concentrations of 0.18-2.8 µg/mL [Dolara 2000].

Essential oil from myrrh inhibited the growth of a variety of Gram-positive and Gram- negative bacteria with MIC values from 0.1-0.4 % [Wanner 2010].

Antiproliferative effect
An aqueous dry extract (7.5 g herbal drug/125 mL water) showed an antiproliferative activity in eight different murine and human cancer cell lines with IC_{50} values of 208-419 µg/mL [Shoemaker 2005].

Myrrh showed an effect on cell viability in a murine neuroblastoma cell line with LC_{50} of 0.158 mg/mL [Mazzio 2009].

Aromatase inhibiting effect
Diterpenes isolated from myrrh showed aromatase inhibiting activity with IC_{50} values of 0.21 µM and 0.32 µM, and significant ($p<0.01$) inhibition of human umbilical vein endothelial cell (HUVEC) growth [Su 2009].

In vivo experiments

Anti-inflammatory effects
In carrageenan-induced paw oedema in rats, a petroleum ether dry extract of myrrh, at an oral dose of 500 mg/kg b.w. given 1h before carrageenan injection, exerted anti-inflammatory activity comparable to the effect of the anti-inflammatory agent oxyphenbutazone 100mg/kg b.w. In the cotton pellet granuloma test the same extract, at an oral daily dose of 500mg/kg b.w. for four consecutive days, demonstrated a 26.49% inhibition of the resulting increase in pellet weight compared to control (saline) [Tariq 1985].

An ethanolic dry extract of myrrh (approximately 6:1), administered intraperitoneally to mice, exerted a significant anti-inflammatory effect ($p<0.05$) at 400 mg/kg b.w. in the xylene-induced ear swelling model. The same extract significantly inhibited cotton pellet granuloma ($p<0.05$) in rats at an oral dose of 400 mg/kg [Atta 1998].

An ethanolic (85%) dry extract and a petroleum ether fraction from the extract at doses of 100 mg/kg b.w. given orally to mice significantly ($p<0.05$) inhibited formalin-induced paw swelling [Su 2011].

Antipyretic effect
Mice with hyperpyrexia induced by administration of a 20% aqueous suspension of brewer's yeast were then administered either an ethanolic (95%) dry extract or a petroleum ether extract (25:1) of myrrh at a dose of 500 mg/kg b.w. A significant antipyretic effect ($p<0.001$ to 0.05) was demonstrated [Mohsin 1989, Tariq 1985].

Stimulation of phagocytosis
Male mice (19±1g) inoculated with *Escherichia coli* were treated intraperitoneally with either a dried ethanolic extract or the unsaponifiable fraction of myrrh, as solutions in aqueous ethanol (10% V/V) at 50 mg/kg b.w. Both treatments stimulated phagocytosis in 80% of the mice compared to controls [Delaveau 1980].

Analgesic effects
In the hot plate test in mice a significant analgesic effect ($p<0.01$) was demonstrated after oral administration of myrrh at 1 mg/kg b.w. [Dolara 1996].

Furanoeudesma-1,3-diene isolated from myrrh showed significant analgesic properties in mice when administered by intracerebroventricular injection at 1.25 mg/kg b.w.($p<0.01$) or orally at 50 mg/kg in the hot plate test, and also at 50 mg/kg in the writhing test. The analgesic effects were reversed by naloxone at 1 mg/kg, indicating an interaction with brain opioid receptors. Furanoeudesma-1,3-diene concentration-dependently displaced the specific binding of [^{3}H]diprenorphine to rat brain membrane *in vitro* [Dolara 1996].

A fraction from myrrh composed of furanodiene-6-one and methoxyfuranoguaia-9-ene-8-one, administered as eye drops at a concentration of 280 µg/mL into the conjunctival sac of rabbits, had a strong local anaesthetic effect ($p<0.01$ compared to the vehicle as control) of about half that of procaine at 100 µg/mL [Dolara 2000].

An ethanolic dry extract of myrrh (approximately 6:1), administered orally to mice, exerted a significant and dose-dependent analgesic effect in the acetic acid-induced writhing test at 200 mg/kg ($p<0.05$) and 400 mg/kg ($p<0.01$) [Atta 1998].

Cytoprotective effect
Oral administration of myrrh to male Wistar albino rats (aged 7-8 weeks) at 250, 500 and 1000 mg/kg b.w. provided significant and dose-dependent protection to the gastric mucosa against the ulcerogenic effects of various necrotizing agents: 80% ethanol, 25% sodium chloride, 0.2 M sodium hydroxide, indometacin 30 mg/kg and combined ethanol 80%-indometacin 2.5 mg/kg ($p<0.05$ to $p<0.001$, depending on the dose). The same suspension significantly and dose-dependently protected against

ethanol-induced depletion of gastric wall mucus ($p<0.05$ at 500 mg/kg; $p<0.001$ at 1000 mg/kg) [Al-Harbi 1997].

Antitumour and cytotoxic effects
After oral treatment of Ehrlich solid tumour (EST)-bearing mice with an aqueous suspension of myrrh at daily doses of 250 or 500 mg/kg b.w., the higher dose produced significant decreases ($p<0.05$) after 25 days and 50 days, in tumour weight, in the viability of EST cells and in levels of DNA, RNA and protein in EST cells. The antitumour potential of myrrh was found to be comparable to that of the cytotoxic drug cyclophosphamide 10mg/kg b.w. [Al-Harbi 1994].

The antitumour activity of an aqueous suspension of myrrh, equivalent to that of cyclophosphamide, has also been demonstrated in Ehrlich ascites carcinoma (EAC) cell-bearing mice. At an oral dose of 500 mg/kg, significant reductions in the DNA ($p<0.05$), RNA ($p<0.01$) and protein ($p<0.01$) contents of EAC cells, and in their viability ($p<0.05$), were observed together with an increased survival rate of the animals (25.1 days) compared to negative control (16.7 days)[Qureshi 1993].

Oral administration of an extract of myrrh (not further specified) demonstrated no anti-tumour activity against Ehrlich ascites carcinoma in mice when given at doses of 100 mg/kg b.w. daily for 6 days or 250 mg/kg b.w. every other day for 6 days, as evaluated by total ascetic volume. The treatment caused a 5 day increase in the median survival time compared to control [El-Naggar 2011].

Hypoglycaemic effects
Intragastric treatment of normal and streptozotocin-induced diabetic rats with a 5% m/V aqueous extract of myrrh (prepared with boiling water and filtration) daily for one week at 10 ml/kg b.w. significantly lowered fasting blood glucose levels ($p<0.05$ for both groups) and, in the oral glucose tolerance test, significantly increased glucose tolerance in both normal ($p<0.02$) and diabetic animals ($p<0.05$) [Al-Awadi 1987].

Oral administration of two fractions (200-250 mg/kg b.w.) and two pure furanosesquiterpenes (150-175 mg/kg) from myrrh (*C. myrrha*) to obese diabetic mice produced significant reductions in blood glucose at 27 hours post-dose ($p<0.005$ in all cases). One active fraction at 200 mg/kg reduced blood glucose by 50% ($p<0.0001$), compared to a 41% reduction with the oral antidiabetic metformin at 250 mg/kg [Ubillas 1999].

Anthelmintic effects
Mice infected with *Schistosoma mansoni* were treated intragastrically with 10 mg/kg b.w. per day of an extract of myrrh for three successive days 6 weeks after infection. Three weeks after treatment, the serum antischistosomal antibody level was significantly decreased ($p<0.0001$). The result was comparable to praziquantel at 250 mg/kg b.w. per day. The level of IL-2 was decreased significantly ($p<0.01$); the level of gamma interferon was not affected [Abdel-Aziz 2006].

Mice infected with 60 cercariae of *Schistosoma mansoni* were orally treated with an undefined myrrh extract (250 mg or 500 mg/kg b.w.), praziquantel as a positive control (250 mg/kg b.w.) or vehicle only, twice a day for three consecutive days. The treatment with the extract and praziquantel caused a significant ($p<0.001$) reduction in the worm burden of the mice, it induced the separation of male-female coupled worms and shifted female worms from their normal habitat to the liver [Badria 2001].

Antischistosomal activity of different myrrh preparations were tested at dosages from 180-10000 mg/kg b.w. in mice and hamsters infected with Schistosoma mansoni strains of different geographical origin. No signs of antibilharzial activity were observed [Botros 2004].

Other effects
Powdered myrrh, administered orally at 100 mg/kg b.w., provided 86% protection against experimental thrombosis in mice ($p<0.05$), comparable to the effect of acetylsalicylic acid at 20 mg/kg [Olajide 1999].

To assess the effect of myrrh on the genotoxic effects and liver oxidising effects of lead acetate, male albino mice (4 months old) received either normal diet (negative control), normal diet with 0.5% lead acetate (positive control) or normal diet with 1% myrrh powder and 0.5% lead acetate for 8 weeks (n=30/group). Addition of myrrh to the diet significantly ($p<0.05$) decreased the level of GSH, increased the activity of GSH-transferase and reduced lipid peroxidation determined in liver homogenate compared to negative control. It significantly ($p<0.05$) reduced genotoxicity of lead acetate, the number of aberrant cells as well as the increased frequency of chromosomal aberrations [El-Ashmawy 2006].

Clinical studies

Anthelmintic effects
Oral treatment of 204 patients suffering from schistosomiasis with myrrh at 10 mg/kg b.w. per day for 3 days in an open study produced a cure rate of 91.7%. Non-responding patients treated for 6 further days with the same dose gave a cure rate of 76.5%, increasing the overall rate to 98%. 20 patients provided biopsy specimens 6 months after treatment and none of them showed living ova [Opdyke1976].

In an open study, 65 patients infected with *Schistosoma mansoni* (n=26) or *S. haematobium* (n=39) were treated with two capsules (600 mg) of a myrrh preparation (not further specified) for six consecutive days. The cure rates after three months were 96.2% and 97.4% respectively [Abo-Madyan 2004].

In an open study, 104 patients with schistosomiasis were treated with 600 mg of an undefined myrrh extract or praziquantel (positive control) at 40 mg/kg b.w. for 3 consecutive days. The treatments were given twice with a 3 week interval. After the first treatment phase the cure rate for the extract was 15.6% compared to 73.7% for praziquantel. After the second treatment phase the rates were 8.9% and 76.3% respectively [Baracat 2005].

Note: The studies above all point to clinical evidence that myrrh is effective against schistosomiasis; however in all cases the administered preparations are not sufficiently characterized.

In a preliminary open study 7 patients with fascioliasis (infection with parasitic liver flukes) were treated orally with a preparation consisting of 8 parts of myrrh resin and 3.5 parts of myrrh volatile oil at 12 mg/kg b.w./day for 6 days. The therapy proved to be effective, with pronounced improvement in the general condition of the patients and amelioration of all symptoms and signs. By the end of treatment a dramatic drop in the egg count was observed and eggs were no longer detectable in the faeces after 3 weeks or after a follow-up period of 3 months. High eosinophilic counts, elevated liver enzymes and *Fasciola* antibody titres returned to nearly normal [Rao 2001].

In an open study, 18 patients infected with *Dicrocoelium dendriticum* (a liver fluke) were given two capsules (600mg) of an unspecified myrrh extract for six successive days. Sixteen of the eighteen patients were followed up for two months and showed clinical and parasitological cure [Al-Mathal 2004].

Antimicrobial effects
In an open study, 13 patients infected with metronidazole- and tinidazole-resistant *Trichomonas vaginalis* were treated with 600 mg of an unspecified myrrh preparation for six to eight successive days. 11 of the 13 patients were reported to be cured by the treatment [El-Sharbini 2009].

Pharmacokinetic properties
No data available.

Preclinical safety data
The acute oral LD_{50} for rats of myrrh oil has been determined as 1.65 g/kg b.w. [Opdyke1976].

The LD_{50} for rats of an extract from myrrh given intragastrically was determined to be 2 g/kg b.w. [Badria 2001].

LD_{50} in mice for an undefined myrrh extract were 3139 mg/kg b.w. given by gastric intubation and 1740 mg/kg b.w. given orally [Botros 2004, El-Naggar 2011].

In the open mouse ear assay, the essential oil, a chloroform dry extract and some isolated constituents from myrrh exhibited irritant potential [Saeed 2004].

Myrrh and the volatile oil of myrrh are reported to be non-irritating, non-sensitizing and non-phototoxic when applied to animal or human skin [Martinetz 1989,Al-Harbi 1994].

Oral toxicity studies of myrrh were carried out in mice using acute doses of 0.5, 1.0 and 3.0 g/kg b.w. and chronic doses of 100 mg/kg/day for 90 days. Compared to controls, no significant differences in mortality, weight gain or biochemical parameters were observed after acute or chronic treatment. After chronic treatment there were significant increases in weight of testes and seminal vesicles ($p<0.05$) and of caudae epididymis ($p<0.01$), and a significant increase in red blood cell count and haemoglobin ($p<0.05$). The toxicity studies supported the safe medicinal use of myrrh [Rao 2001].

Genotoxicity and cytotoxicity
Myrrh administered orally to normal mice for 7 days at 125-500 mg/kg b.w. per day as an aqueous suspension showed no mutagenicity in the micronucleus test. It caused a significant, dose-dependent reduction in the RNA content of hepatic cells ($p<0.01$ at 250 mg/kg), but not the DNA or protein content, and a highly significant, dose-dependent, mitosis-depressant effect in femoral cells ($p<0.001$) [Qureshi 1993, Al-Harbi 1994].

Clinical safety data
Myrrh was well tolerated with only mild and transient side effects when administered orally to 204 patients with schistosomiasis at 10 mg/kg b.w./day for 3-9 days [Sheir 2001].

No signs of toxicity or adverse effects were observed from treatment of 7 patients with fascioliasis with myrrh resin/volatile oil at 12 mg/kg b.w. for 6 days [Massoud 2001].

Ethnopharmacological evidence suggests that myrrh has been extensively used both internally and externally without serious adverse effects [Martinetz 1989].

No side effects were reported in an open study involving 18 dicrocoeliasis patients treated for six days with a dose of 600 mg of an unspecified myrrh extract [Al-Mathal 2004].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

MYRTILLI FRUCTUS

2014

Bilberry Fruit

DEFINITION

Bilberry fruit, dried consists of the dried ripe fruit of *Vaccinium myrtillus* L., containing a minimum of 1.0 percent of tannins, expressed as pyrogallol ($C_6H_6O_3$; M_r 126.1) calculated with reference to the dried drug.

Bilberry fruit, fresh consists of the fresh or frozen ripe fruit of *Vaccinium myrtillus* L., containing a minimum of 0.30 per cent of anthocyanins, expressed as cyanidin-3-*O*-glucoside chloride (chrysanthemin, $C_{21}H_{21}ClO_{11}$; M_r 484.8) calculated with reference to the dried drug.

Fresh bilberry fruit dry extract, refined and standardised, produced from Bilberry fruit, fresh using ethanol (96 per cent V/V) or methanol (minimum 60 per cent V/V). It contains 32.4 per cent to 39.6 per cent of anthocyanins, expressed as cyanidin 3-*O*-glucoside chloride [chrysanthemin ($C_{21}H_{21}ClO_{11}$); M_r 484.8) calculated with reference to the dried drug*.

The materials comply with the respective monographs of the European Pharmacopoeia [Bilberry fruit, dried; Bilberry fruit, fresh; Fresh bilberry fruit dry extract, refined and standardised].

CONSTITUENTS

Bilberry fruit, dried

Tannins and tannin precursors: up to 4%, mainly catechol tannins, also catechin and epicatechin; Procyanidins: B-1, B-2, B-3 and B-4; Anthocyanins: 0.5% glycosides of mainly delphinidin, cyanidin and petunidin; Flavonoids: including hyperoside, isoquercitrin, quercetin, astragalin; Iridoids: asperuloside; Caffeic acid derivatives: chlorogenic and other caffeoylquinic acids; Other constituents: resveratrol, pectins, vitamin C, β-carotene [Friedrich 1973; Baj 1983; Jänicke 2003; Wichtl 2009].

Bilberry fruit, fresh
Fresh bilberry fruit dry extract, refined and standardised

Anthocyanins: mono- and di-saccharides of delphinidin, cyanidin, petunidin, peonidin and malvidin, highest amounts occurring in berry skins; Anthocyanidins: delphinidin, cyanidin, petunidin, peonidin, malvidin; Catechins: (+)-catechin, (-)-epicatechin, epigallocatechin gallate; Flavonols: quercetin, myricetin; Phenolic acids: ferulic, p-coumaric, m-coumaric, caffeic, chlorogenic, protocatechuic, syringic and gallic; Procyanidins: dimers and trimers A-type derived from (-)-epicatechin; Stilbenes: trans-resveratrol; Other constituents: triterpenes, scopoletin, aliphatic organic alcohols [Jaakola 2002; Roy 2002; Du 2004; Viljanen 2004; Ehala 2005; Faria 2005; Määttä-Riihinen 2005; Burdulis 2007; Cassinese 2007; Milbury 2007; Bao 2008a; Bao 2008b; Latti 2008; Ogawa 2008; Burdulis 2009; Thomasset 2009; Akerström 2010; Karlsen 2010].

CLINICAL PARTICULARS

Therapeutic indications

Internal use
Extracts of bilberry fruit enriched with anthocyanins: supportive treatment of problems related to varicose veins such as painful and heavy legs, peripheral vascular insufficiency and microcirculatory disorders of the eye [Ghiringhelli 1978; Passariello 1979; Grismondi 1980; Tori 1980; Nuti 1980; Scharrer 1981; Allegra 1982; Signorini 1983a; Signorini 1983b; Corsi 1985; Gatta 1988; Morazzoni 1996].

Dried bilberry fruit: supportive treatment of acute non-specific diarrhoea. In this indication the efficacy is plausible due to long-standing use [Schilcher 1997;

1*The HPLC-based assay defines anthocyanins (Syn. anthocyanosides) content of the Fresh bilberry fruit dry extract as 36%, which corresponds to the 25% specification determined by spectrophotometry based on anthocyanidins [Penman 2006; Cassinese 2007; Ulbricht 2009].

Jänicke 2003; Wichtl 2009; Schilcher 2010].

External use
Topical treatment of mild inflammation of mucous membranes of the mouth and throat and for superficial wounds. In this indication the efficacy is plausible due to long-standing use [Jänicke 2003; Wichtl 2009].

Posology and method of administration

Internal use
Dried bilberry fruit: For adults and children from 10 years, 20 to 60 g daily, taken with water [Dorsch 2002; Jänicke 2003; Wichtl 2009; Schilcher 2010].

Decoction: 5-10 g of dried fruit boiled for 10 minutes in 150 mL water and drunk cold several times daily [Jänicke 2003; Blaschek 2007; Wichtl 2009].

Cold macerate: 5-10 g dried fruit soaked in 150 ml water for 2 hours and drunk several times daily [Jänicke 2003; Blaschek 2007; Wichtl 2009].

Fluid extract [1:1]: 3 to 6 ml daily [Mills 2005].

Dry standardized extract containing 36% of anthocyanins: 60 to 160 mg three times daily (equivalent to 65 to 173 mg anthocyanins daily) [Alfieri 1964; Bonacina 1973; Lietti 1976; Robert 1977; Detre 1986; Virno 1986; Bertuglia 1995; Sweetman 2008].

Topical use
A 10% decoction as a gargle or mouthwash [Blumenthal 2003; Sweetman 2008; Wichtl 2009].

Method of administration
For oral administration or local application.

Duration of use
No restriction.
If diarrhoea persists for more than 3-4 days medical advice should be sought. In microcirculatory disorders a use of at least 4 to 8 weeks is recommended [Blumenthal 2003].

Contra-indications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
Due to the potential for bilberries to enhance the antiplatelet effect of acetylsalicylic acid and other NSAIDs, bilberries should be used with caution by patients with haemorrhagic disorders and those taking warfarin or antiplatelet drugs [Morazzoni 1990; Rasetti 1996; Laplaud 1997; Abebe 2002; Mills 2005].

Pregnancy and lactation
The dry extract is well tolerated in pregnancy. Bilberry has been used safely in high doses in pregnant women with varicose veins and haemorrhoids [Grismondi 1980; Teglio 1987; De Smet 1993].

Scientific evidence for the safe use of bilberry during lactation is not available.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antioxidant activity
An anthocyanin-rich extract of bilberry fruit was reported to be a potent scavenger of free radicals, behaving both as a scavenger against superoxide anion [Salvayre 1981; Meunier 1989; Martin- Aragón 1998; Martin- Aragón 1999] and as an inhibitor of lipid peroxidation induced by adenosine diphosphate (ADP)/Fe^{2+} and ascorbate in liver microsomes [Salvayre 1981; Martin- Aragón 1998; Martin- Aragón 1999].

The K^+ loss induced by free radicals in human erythrocytes, as well as the cellular damage caused by oxidant compounds such as daunomycin and paraquat, was inhibited by an anthocyanin-rich extract [Maridonneau 1982; Mavelli 1984].

An aqueous extract of bilberry fruit was shown to have a potent protective action on human low density lipoprotein (LDL) during copper-mediated oxidation [Laplaud 1997] and a standardized extract containing 37% of anthocyanins prevented photo-induced oxidation of human LDL and fragmentation of apoprotein [Rasetti 1996/7].

The peroxy-radical scavenging capacity of berry extracts was studied using the Oxygen Radical Absorbing Capacity (ORAC) assay. The ORAC value (expressed using Trolox equivalents per g) for bilberry extract was 44 [Roy 2002].

The antioxidant activity of a bilberry extract (573 mg total phenolic compounds / g dry weight containing 94.8% anthocyanins) was investigated in a lactalbumin-liposome system at concentrations of 1.4, 4.2 and 8.4 µg / mL of liposome sample. The extracts showed an effective dose-dependent antioxidant activity towards protein and lipid oxidation. Anthocyanins were the major contributors to the antioxidant effect by inhibiting both hexanal and protein carbonyl formation [Viljanen 2004].

An ethanolic extract of fresh berries (258 mg/L total phenolics) had an antiradical activity (assessed by DPPH method) of 5.37 (µM Trolox equivalents). The extract provided protection of a liposomal membrane against peroxyl radicals by increasing the induction time of oxidation [Faria 2005].

To study structure-activity relationships and potential synergisms, antioxidant activities of 15 bilberry phenolics were evaluated. The potency of activity towards the superoxide radical was in the order: delphinidin > petunidin > malvidin=cyanidin > (+)-catechin > peonidin > pelargonidin. The activity towards the peroxynitrite radical (ONOO-) was: delphinidin > cyanidin=petunidin > malvidin = (+)-catechin > peonidin > pelargonidins [Rahman 2006].

In an assay using cytochrome *C*-enhanced 6-hydroxydopamine oxidation reaction a 50% inhibition was observed with an aqueous bilberry extract (7 µM of total anthocyanin) [Yao 2007].

Effects on vision
Pyridinium bisretinoid A2E, an autofluorescent pigment

accumulating in human adult retinal pigment (ARPE) cells with age and other retinal disorders, can mediate a detergent-like perturbation of cell membranes and light-induced damage to cells. Light-exposed A2E-laden ARPE cells exhibit a propensity for apoptosis via generation of epoxides which then interact with DNA. Incubation of the cells with a bilberry extract (40mM) reduced A2E-epoxidation, incidence of DNA damage and cell death [Sparrow 2003].

A water-soluble fraction of a bilberry extract was found to reduce A2E photooxidation. Separated single anthocyanins (100 µM) suppressed the photooxidation of A2E. The ARPE cells that had been incubated with anthocyanins (100 µM) exhibited an increased resistance to A2E-induced membrane damage [Jang 2005].

A bilberry extract (total anthocyanin content 28.1% cyanidin-3-glucoside equivalent; total phenol content 61.8% catechin equivalent) was found to upregulate the oxidative stress defence enzymes haeme oxygenase-1 and glutathione *S*-transferase-pi in retinal pigment epithelial cells [Milbury 2007].

A bilberry extract (10 µg/mL) and anthocyanidins (cyanidin at 10 µM, delphinidin at 30 µM, malvidin at 10 µM) significantly inhibited 3-(4-morpholinyl) sydnonimine hydrochloride-induced retinal ganglion cell death and decreased intracellular radical formation. Each inhibited the production of thiobarbituric acid reactive substance (TBARS) in a concentration-dependent manner, the IC_{50} values being 1.0 µg/mL, 0.7, 1.9 and 8.3 µM respectively versus vehicle ($p<0.05$) [Matsunaga 2009].

A study examined the effects of anthocyanins on the regeneration of the photoreceptor rhodopsin using frog rod outer segment membranes. Cyanidin-3-glycosides stimulated the regeneration, but the corresponding delphinidin glycosides showed no significant effect [Matsumoto 2003].

In frog rod outer segment membranes cyanidin-3-glucoside [C3G] was found to bind directly with rhodopsin depending on pH [Yanamala 2009]. Further work confirmed the C3G-enhanced regeneration [Tirupula 2009].

Anti-angiogenic activity
The antiangiogenic activity of a standardised bilberry extract (25% anthocyanins) was evaluated using the chick chorio-allantoic membrane (CAM) assay. A 100 ng/50 µl concentration resulted in inhibition (Score -2) compared to control (Score +2) [Ozgurtas 2008].

A bilberry extract (50 µg polyphenols/mL) showed a 96% inhibition of H_2O_2- induced vascular endothelial growth factor (VEGF) expression by human HaCaT keratinocytes, compared to control (76%) ($p<0.05$) [Roy 2002].

A bilberry extract (25% anthocyanins) at 0.3-30 µg/ml inhibited both tube formation and migration of human umbilical vein endothelial cells (HUVECs) induced by vascular endothelial growth factor-A (VEGF-A). In addition the bilberry extract inhibited VEGF-A-induced proliferation of HUVECs and VEGF-A-induced phosphorylations of extracellular signal-regulated kinase 1/2 and serine/threonine protein kinase family protein kinase B, but not that of phospholipase C-gamma [Matsunaga 2007].

In a second study the inhibitory effects induced by individual anthocyanidins (delphinidin, cyanidin and malvidin) at 3 and 10µM significantly inhibited VEGF-induced tube formation ($p<0.01$) in a co-culture of HUVECs and fibroblasts. Each anthocyanidin (0.3 – 10µM) also scavenged the DPPH radical in a dose-dependent manner. The effects were weaker than those produced by the bilberry extract (25% anthocyanins) at 30 µg/mL [Matsunaga 2010].

Effect on cardiovascular tissues
An anthocyanin-rich extract of bilberry fruit inhibited proteolytic enzymes such as elastase [Jonadet 1983] and interacted with collagen metabolism by cross-linking collagen fibres, making them more resistant to collagenase action [Robert 1977] and reducing the biosynthesis of polymeric collagen [Boniface 1982].

An anthocyanin-rich standardized extract (corresponding to 25% of anthocyanidins) had a slightly relaxing effect on various isolated vascular smooth muscle preparations and reduced the response to contraction inducers such as serotonin and barium [Bettini 1984a; Bettini 1984b; Bettini 1984c; Bettini 1985].

Application of a bilberry extract (12.1% total anthocyanins and 35.7% total phenolics) directly to pig coronary arterial rings resulted in a dose- and endothelium-dependent vasorelaxation (% maximal relaxation at 5 mg total anthocyanins /L was 59 ± 10) [Bell 2006].

A bilberry extract (standardized for 25% anthocyanidin) was evaluated for effects on ACE in cultured endothelial cells. Doses of the extract (6.25, 12.5, 25, 50 and 100 µg/mL) resulted in a significant and dose-dependent inhibition of the ACE activity ($p<0.001$). Reference anthocyanidins had no significant effect [Persson 2009].

Bilberry anthocyanins isolated from fresh ripe berries were evaluated for their intracellular capacity to inhibit peroxy radical formation on endothelial cells (EA.hy926). Anthocyanins were significantly active ($p<0.001$) at low concentrations (<0.5mg/L) with a saturable effect being observed >0.5 mg/L. Coronary flow (CF) of isolated rat hearts in experiments with 40-min ischaemia followed by reperfusion indicated a concentration-dependent bi-phasic response: vasodilation at ≤1mg/L ($p<0.05$) and vasoconstriction at ≥10 mg/L up to 50 mg/L. Perfusion of isolated rat hearts with low anthocyanin concentrations (0.01 – 1 mg/L) significantly attenuated the ischaemia-reperfusion (I-R) injury as evidenced by decrease in the release rate of lactate dehydrogenase (LDH), increase in postischaemic coronary flow and decrease in the incidence and duration of reperfusion arrhythmias (heart arrest, ventricular fibrillation, ventricular tachycardia, ventricular premature complexes). High concentrations (5 - 50 mg/L) diminished cardioprotection and showed cardiotoxic activity [Ziberna 2010].

Antiaggregatory effects
A standardized extract of bilberry fruit showed activity against aggregation induced by ADP, collagen and sodium arachidonate in rabbit platelet-rich plasma [Morazzoni 1990]. This was confirmed *ex vivo* on ADP- and collagen-induced aggregation of platelets obtained from the blood of 30 healthy volunteers given 480 mg/day of the standardized extract orally for 30-60 days [Pulliero 1989].

An anthocyanin extract of bilberry fruit also inhibited *in vitro* platelet aggregation induced by ADP or adrenaline in human plasma [Serranillos 1983].

Wound healing effects
Pre-treatment (1 h) with a bilberry extract (25% anthocyanins) increased the viability of UV-A irradiated (20 J/cm^2) keratinocytes (HaCaT cells) in a dose-dependent manner, with 100 mg/L providing nearly 50% protection ($p<0.05$). Pre- and post-treatment (4 h) of the cells with the bilberry extract (25–100

mg/L) attenuated the UVA-induced reactive oxygen species (ROS) generation ($p<0.05$) [Svobodova 2008].

Further evaluation of the photoprotective effects of bilberry fruit extract (25% w/w anthocyanins) on UVB-induced phototoxic stress (200 mJ/cm^2) showed that pre-treatment (1 h) of HaCaT cells with the extract (5 – 50 mg/L) and post-treatment (4 h) with 5 and 50 mg/L, reduced the extent of DNA breakage ($p<0.05$), and laddering, together with caspase-3 and -9 activity ($p<0.05$). Pretreatment with the extract before UVB exposure also significantly ($p<0.05$) decreased reactive oxygen or nitrogen species (RONS) generation and partially diminished IL-expression [Svobodova 2009].

Treatment of fibroblasts with anthocyanins (cyanidin-3-glucoside (72%), delphinidin-3-glucoside (20%) and petunidin-3-glucoside (6%)) after 24 h showed a significant increase in migration at 100 µg/ml ($p<0.05$), while the migration of keratinocytes increased significantly at 50 and 100 µg/mL compared to control ($p<0.05$). Treatment with anthocyanins for 48 h significantly stimulated the migration of both human dermal fibroblasts and keratinocytes at 50 and 100 µg/mL ($p<0.001$). Treatment of cells with anthocyanins stimulated wound-induced VEGF production in fibroblasts and keratinocytes. However, anthocyanins inhibited ROS accumulation and VEGF production in TNF-α-stimulated endothelial cells. Anthocyanin treatment also reduced, in a dose-dependent manner, the adhesion of inflammatory monocytes to endothelial cells. Anthocyanins also blocked both the translocation of NF-κB p65 into the nucleus and the phosphorylation of the inhibitory factor κBα [Nizamutdinova 2009].

Anti-inflammatory activity
The effects of a standardised bilberry extract (36% anthocyanins) on genome-wide gene expression were investigated in an inflammatory cell model (RAW264). Cells were pretreated with or without 75 µg/mL bilberry extracts for 30 mins and then exposed to 40 ng/mL lipopolysaccharide (LPS) for another 6 hrs. The induction of pro-inflammatory genes, including TNF, IL-1β, IL-6, TNC, PTGS2 and COX-2 were significantly reduced by bilberry ($p<0.001$ vs LPS only) [Chen 2008].

In cultured human monocytes (U937-3XκB-LUC cells) anthocyanins (100 mg/L) isolated from bilberries and black-currants efficiently suppressed LPS-induced activation of NF-κB [Karlsen 2007].

Human monocytic cells (ATCC CRL-1593.2) were co-incubated with 13 polyphenols to evaluate their ability to modulate LPS-induced NF-κB activity. Quercetin inhibited the NF-κB activation in a dose-dependent manner as compared with control cells (77% and 95% at 25 and 50 µmol/L (respectively, both $p<0.001$). Resveratrol (50 µmol/L) and epicatechin (25 µmol/L) inhibited the LPS-induced NF-κB activation by 79% ($p=0.020$) and 32% ($p<0.003$) respectively. Petunidin (50 µmol/L) and delphinidin (50 µmol/L) increased LPS-induced NF-κB to respectively 245 and 146% of controls ($p= 0.003$ and $p=0.007$) [Karlsen 2010].

Antimicrobial / gastroprotective activity
A bilberry extract (0.25%) significantly ($p<0.05$) inhibited the growth of *Helicobacter pylori* (ATCC strain 49503) compared to controls and increased susceptibility of *H. pylori* to clarithromycin (15 µg/mL). With a 1% concentration of the extract, >90% inhibition was observed, with and without clarithromycin [Chatterjee 2004].

Bilberry extract (1mg/mL) showed strong inhibition against *Escherichia coli* (strains 50 and CM871) [Puupponen-Pimiä 2001]. Phenolic extracts have also been shown to be effective against *Bacillus cereus*, *Salmonella enterica* sv. *Typhimurium* and sv. *Infantis*, *Staphylococcus aureus*, *Clostridium perfringens* and *Helicobacter pylori*. Activity is associated with phenolics, mainly anthocyanins [Puupponen-Pimiä 2001; Puupponen-Pimiä 2005; Nohynek 2006; Puupponen-Pimiä 2008].

Sugars and low molecular weight phenolic compounds of bilberry juice were found to inhibit *Streptococcus pneumoniae* binding to human bronchial cells (Calu-3). Adhesion inhibition was 52% with a fraction concentration of 9 mg/g [Huttunen 2011].

Fractions of bilberry juice (mainly anthocyanins, proanthocyanidins and flavonol glycosides) inhibited and reversed co-aggregation of pairs of *Streptococcus mutans* with *Fusobacterium nucleatum* or *Actinomyces naeslundii*, species which are common in dental plaque [Riihinen 2011].

Polyphenolic fractions of bilberry juice containing mainly anthocyanins and proanthocyanidins, between concentrations of 5-50 µg/mL, were found to significantly inhibit adhesion of *Neisseria meningitides* to HEC-1B human epithelial cells when compared to control ($p<0.05$) [Toivanen 2011].

Antiproliferative and apoptotic activity
A lyophilized ethanol extract of frozen bilberries (55.1 mg/g of total phenolics, 26.3 mg/g of total anthocyanins) showed a DPPH radical scavenging activity of 288 (µmol of Trolox/g). The extract decreased the number of viable human promyelocytic leukaemia (HL 60) cells by 84 and 88% at a concentration of 4 and 6 mg/mL respectively and the number of viable human colon carcinoma (HCT116) cells by 66% and 97% at 2 and 4 mg/mL respectively. HL60 cell growth was inhibited when incubated with extract concentrations from 0.5 to 4 mg/mL for 24 and 48 h. In contrast HCT116 cell growth showed inhibition at 1-4 mg/mL only after 48 h incubation. The bilberry extract induced apoptotic cell bodies in HL60 cells and nucleosomal DNA fragmentation in HL60 cells but not in HCT116 cells [Katsube 2003].

Pretreatment of cultured mouse JB6 cells with cyanidin-3-glucoside (C3G) inhibited UVB- and TPA-induced transactivation of NF-κB and AP-1 as well as expression of COX-2 and TNF-α. These inhibitory effects appeared to be mediated through the inhibition of MAPK activity. C3G (10 - 40µM) significantly inhibited, and at a concentration of 80 µM completely abolished, TPA-induced neoplastic transformation in JB6 cells ($p\leq0.05$). In addition C3G (10 - 40µM) inhibited proliferation of a human lung carcinoma cell line A549 [Ding 2006].

A methanolic extract from fresh bilberries (2:1) contained anthocyanins (12.8 mg/mL) and flavonols (0.29 mg/mL). For the determination of cell proliferation, HT-29 colon cancer cells were exposed to 200 µL of culture medium containing 0-60 mg/mL of berry extract or pure compounds (0-100 µg/mL) for 24 h. Bilberry extracts showed significant ($p<0.001$) growth inhibition (30% cell reduction) at 10 mg/mL. The bilberry extract had no effect on DNA fragmentation after 48 h at concentrations up to 10 mg/mL. However, exposure of the HT-29 cells to higher concentrations (20-60 mg/mL) resulted in pronounced fragmentation [Wu 2007].

A bilberry extract was tested for growth inhibition (IC_{50}) using a human colorectal adenocarcinoma (HT29) cell line. The sulforhodamine B assay was applied to determine cell growth. The IC_{50} for bilberry extract was found to be 32.2 µg/mL of cyanidin-3-glucoside equivalent [Jing 2008].

A standardised anthocyanin-rich bilberry extract (36%

anthocyanins) reduced receptor tyrosine kinase (RTK) domains of epidermal growth factor (EGFR, ErbB1) and ErbB2-4 receptors and the vascular endothelial growth factor receptors (VEGFR-2 and VEGFR-3), with preferential inhibition of VEGFR-2 and EGFR (≤ 3.4 µg/mL). Ligand-induced autophosphorylation of human vulva carcinoma or porcine aortic endothelial cells was suppressed, with ErbB3 and VEGFR-3 being preferentially inhibited. The extract completely abolished VEGFR-3 phosphorylation at concentrations of ≥50 µg/mL [Teller 2009].

In human breast cancer cells (MCF7) a bilberry extract inhibited proliferation in a concentration-dependent manner, without inhibiting microtubule polymerization or mitosis. Significant inhibition of proliferation ($p<0.05$) occurred with bilberry extract concentrations >0.25 mg/mL, with an IC_{50} of 0.43 mg/mL. At higher concentrations (0.5-1 mg/mL) inhibition of polymerization (~30%) did occur with an increase in the fraction of cells at the G_2/M phase, together with destruction of microtubules and formation of punctate tubulin aggregates in the cells [Nguyen 2010].

Various anthocyanins and anthocyanidins were exposed to the human efflux transporters-multidrug resistance protein 1 (MDR1) and breast cancer resistance protein (BCRP) using dye efflux, ATPase and vesicular transport assays. Malvidin, petunidin, malvidin-3-galactoside, cyanidin-3-galactoside, peonidin-3-glucoside and cyanidin-3-glucoside emerged as potential BCRP substrates, while others (including cyanidin, peonidin, pelargonidin, delphinidin) emerged as potential inhibitors of BCRP. Some exhibited bimodal activities, with malvidin, malvidin-3-galactoside and petunidin serving as BCRP substrates at low concentrations and BCRP inhibitors at higher concentrations. Aglycones exerted only mild inhibitory activity on MDR1 [Dreiseitel 2009].

Other effects
Pre- and co-incubation of human colon adenocarcinoma cells (HT29) with a standardized bilberry extract (36% anthocyanins) at concentrations ≥1µg/mL significantly suppressed ($p\leq0.001$) the strand-breaking effects of camptothecin and significantly diminished doxorubicin-mediated DNA strand breaks at concentrations ≥ 1µg/mL ($p\leq0.001$) [Esselen 2011].

Human HepG2 cells were incubated for 24 hrs with varying C3G concentrations (5–100 µmol/L) and assayed for cholesteryl ester transfer protein (CETP) activity. Concentrations of 5 µmol and above significantly suppressed CETP activity ($p<0.001$) compared to the untreated control [Qin 2009].

In vivo experiments

Antioxidant activity
Oral pre-treatment of mice with 250 or 500 mg/kg of an anthocyanin-rich extract of bilberry fruit inhibited liver peroxidation stimulated by $FeCl_2$, ascorbic acid and ADP. The malondialdehyde content in the liver was significantly reduced ($p<0.05$) [Martin-Aragon 1999].

Oral administration of an anthocyanin-enriched bilberry extract (42% anthocyanins) to mice (n=10) at 50, 100 and 200 mg/kg/day for 5 days showed significant decreases ($p<0.001$) in plasma alanine aminotransferase (ALAT) levels at all doses, with the 200 mg/kg/day dose having an ALAT level of 17.23 ± 2.49 U/L compared to 107.68 ± 3.19 U/L 18 h in restraint stressed mice and 18.08 ± 1.46 U/L in starved controls. Extracts also significantly ($p<0.001$) increased GSH and Vitamin C levels and significantly decreased MDA and nitric oxide (NO) levels in liver tissues at the highest dose [Bao 2008a].

In another experiment the same anthocyanin-enriched bilberry extract (42% anthocyanins) was given orally to mice at 50, 100 and 200 mg/kg/day for 5 days. After the final treatment, potassium bromate ($KBrO_3$), an oxidizing agent and potent nephrotoxin, was given as a single intraperitoneal injection to mice (n=10) at a dose of 200mg/kg. Serum blood urea nitrogen (BUN) and creatinine levels were significantly higher in the $KBrO_3$-treated animals when compared with control (247.31 ± 3.22 mg/L vs 215.10 ± 2.82 mg/L; 22.26 ± 1.75 µg/mL vs 9.91 ± 0.86 µg/mL respectively). The 5-day oral intake of the extract significantly ($p<0.001$) reduced levels of BUN and serum creatinine to normal levels and decreased kidney MDA, NO and xanthine oxidase levels. Improved ORAC levels in kidney tissue were also observed indicating a reduced degree of oxidative stress and kidney damage [Bao 2008b]. Administration of the extract also elevated the Na^+/K^+-ATPase activity and mitochondrial potential which was reduced in the stressed group. Bilberry extract had a protective effect on the liver by scavenging free radicals and attenuating mitochondrial dysfunction [Bao 2010].

A standardized bilberry fruit extract (36% anthocyanins) was evaluated in carbon tetrachloride (CCl_4)-induced hepatic fibrosis. Balb/C mice were treated i.p. with CCl_4 dissolved in olive oil (20% V/V; 2ml/kg) twice a week for 7 weeks. Control animals received the vehicle only. The bilberry extract in saline (1, 5 and 10 mg/kg to groups 4, 5 and 6 respectively) was then given daily for 15 days prior to sacrifice. Results showed that bilberry extract, in a dose-dependent manner, reduced hepatic hydroxyproline (an indicator of hepatic collagen) from 945 µg/g liver (CCl_4 + saline) to 248 µg/g liver (CCl_4 + BE 10 mg/kg; $p<0.05$) vs 198 µg/g liver (control). The extract (10 mg/kg) markedly attenuated oxidative stress, decreased TNF-α, TGF-β1 and α-smooth muscle actin (α-SMA) expression and eliminated hepatic collagen deposits. The extract reduced liver fibrosis by decreasing oxidative stress and inactivating hepatic stellate cells via down-regulation of the fibrogenic cytokines TNF-α and TGF-β1 [Domitrovic 2011].

Effects on vision / ophthalmic activity
An anthocyanin-rich extract of bilberry fruit, administered intravenously to rabbits at 3.2 mg/kg, reduced the permeability of vessels of the ciliary body, which had been increased by ocular puncture [Virno 1986].

A mixture of anthocyanins administered intravenously to rabbits at 160 mg/kg promoted dark adaptation after dazzling [Alfieri 1964].

Senescence-accelerated OXYS rats with early senile cataract and macular degeneration were given control diets or supplementation with 25% bilberry extract (20 mg/kg b.w. = 4.5 mg anthocyanidin) or vitamin E (40 mg/kg) for comparison. After 3 months 70% of control rats had cataracts and macular degeneration. Supplementation with vitamin E showed no significant effects. In contrast the extract completely prevented impairments in the lenses and retina. Both antioxidants decreased lipid peroxides in the retina and serum [Fursova 2005].

Administration of an ethanolic dry extract of bilberry to mice by intravitreal injection (300 ng per eye) inhibited the formation of neovascular tufts during oxygen-induced retinopathy, in comparison to saline [Matsunaga 2007].

This extract was further evaluated for the effects on *N*-methyl-D-aspartic acid (NMDA)-induced retinal damage using haematoxylin-eosin and terminal deoxynucleotidyl transfer-mediated dUTP nick-end labelling (TUNEL) staining. Intravitreal injection of bilberry extract (100 µg per eye co-injected with NMDA at 5 nmol) significantly inhibited the morphological

retinal damage and increase in TUNEL-positive cells in the ganglion cell layer (both the GCL cell count and the IPL thickness) [Matsunaga 2009].

Ocular inflammation (uveitis) was induced in mice by a foot-pad injection of lipopolysaccharide (100 mg/mouse). Oral administration of a bilberry extract (42% anthocyanins) at doses of 50, 100 and 200 mg/kg/day for 5 days before challenge significantly reduced the ocular nitric oxide levels, especially at the highest dose ($p<0.001$). Also the malondialdehyde level was decreased, while increased levels were found in ORAC, glutathione and vitamin C, as well as increased activities of superoxide dismutase and glutathione peroxidase. Increased expressions of Cu/Zn superoxide dismutase, Mn superoxide dismutase and glutathione peroxidase were also found [Yao 2010].

In a similar experiment an anthocyanin-rich bilberry extract (39% anthocyanins; 500 mg/kg b.w.) or PBS as control, were administered orally to mice for 4 days. Three hours after the last administration animals received a single intraperitoneal injection of lipopolysaccharide (6 mg/kg b.w.) to induce uveitis and retinal inflammation (EIU). Pretreatment with the bilberry extract had a protective effect on visual functioning during retinal inflammation. Anthocyanin treatment was found to preserve rhodopsin levels ($p<0.05$), suppress an increase of the pro-inflammatory cytokine IL-6 ($p<0.05$), reduce oxidative stress ($p<0.01$), significantly suppress a-wave and b-wave amplitudes ($p<0.05$ and $p<0.01$ respectively) and to suppress NF-κB ($p<0.01$) in the inflamed retina [Miyake 2012].

Effects on glucose and lipid metabolism (anti-diabetic activity)
Bilberry extract (375 g anthocyanins/kg) included in the diet (10 g anthocyanin/kg diet) of type 2 diabetic mice (male KK-A^y) for 5 weeks, significantly reduced blood glucose concentration and enhanced insulin sensitivity ($p<0.05$) via activation of AMP-activated protein kinase (AMPK). Activation occurred in white adipose tissue, skeletal muscle and the liver and was accompanied by upregulation of glucose transporter 4 in white adipose tissue and skeletal muscle, and suppression of glucose production and lipid content in the liver. At the same time acetyl-CoA carboxylase was inactivated and PPARα, acyl-CoA oxidase and carnitine palmitoyltransferase-1A were upregulated in the liver. After 5 weeks there was no difference in body weight gain or adipose tissue weight between the test and control groups. However, liver weight was significantly lower in the group receiving the bilberry extract ($p<0.05$). Compared with the control group total lipid, triglyceride and cholesterol contents of the liver were significantly reduced in the test group, while triglyceride and total cholesterol concentrations in serum were also significantly lowered ($p<0.05$) [Takikawa 2010].

KK-A^y mice were fed control or control + 0.2% of C3G diet for 5 weeks. Dietary C3G significantly reduced blood glucose concentration and enhanced insulin sensitivity ($p<0.05$). C3G upregulated the glucose transporter 4 and downregulated retinol binding protein 4 in the white adipose tissue, which was accompanied by downregulation of the inflammatory adipocytokines (monocyte chemoattractant protein-1 and TNF-α) ($p<0.05$ for both) [Sasaki 2007].

Vasoprotective activity
Anthocyanin-rich extracts of bilberry fruit exert modulating effects on capillary resistance and permeability, as was demonstrated in various animal models [Lietti 1976; Robert 1977; Detre 1986]. For example, an extract administered orally to rabbits at 200-400 mg/kg protected against capillary permeability induced by topical application of chloroform [Lietti 1976].

Treatment of rats with bilberry anthocyanins for 12 days before the induction of hypertension kept the blood-brain barrier permeability normal and limited the increase in vascular permeability in the skin and the aorta wall [Detre 1986].

When administered orally to rats at 100-200 mg/kg, or intra-peritoneally or intramuscularly at 25-100 mg/kg, the extract protected against capillary lesions induced by intradermal injection of bradykinin [Lietti 1976].

The same extract was found to antagonise damage induced by ischaemia-reperfusion in the hamster cheek-pouch micro-circulation model after oral administration at 100 mg/kg for 4 weeks [Bertuglia 1995].

Effects of a bilberry extract on arteriolar vasomotion were assessed in cheek pouch microcirculation of anaesthetised hamsters and in skeletal muscle microvasculature of unanaesthetised hamster skin fold window preparations. Intravenous injection of the extract induced vasomotion in cheek pouch arterioles and terminal arterioles with higher frequency in smaller vessels. In the skeletal muscle arteriolar networks the extract increased vasomotion frequency and amplitude in all vessel types. [Colantuoni 1991].

The effects of anthocyanins on skeletal muscle vascular permeabililty were evaluated in streptozotocin-induced diabetic rats. Animals (n=11) received bilberry extract (40 mg/kg) daily in drinking water or water only (n=10). Changes in vascular permeability were determined by measuring the capillary filtration of intravenously administered ^{99m}technetium-labelled albumin (CFA), inducing venous compression in a hindquarter with a tourniquet and measuring the radioactivity externally on the limb before (time 0), during (after 6 weeks) and after removal of compression (after 12 weeks). Interstitial albumin retention (AR) was significantly higher in the diabetic rats than the controls. In the groups receiving the extract AR decreased significantly ($p=0.015$) after 6 and 12 weeks [Cohen-Boulakia 2000].

Antiatherogenic (atheroprotective) activity
An anthocyanin-rich extract of bilberry fruit, administered intraperitoneally at 100 mg/kg for 45 days to rabbits fed on a cholesterol-rich diet, reduced the proliferation of intima and calcium and lipid deposition on the aortic wall [Kadar 1979].

Two bilberry extracts, one rich in anthocyanins extracted from bilberries (52% total anthocyanins) and one extracted from yeast-fermented bilberries (almost devoid of typical anthocyanins but rich in complex polymers) were evaluated for their effects on the development of atherosclerosis in apolipoprotein E-deficient mice. For 16 weeks mice received a diet supplemented with 0.02% of either extract. Both bilberry extracts caused a significant reduction in lipid deposits. The atherosclerotic lesions area was decreased in the anthocyanin-rich group by 15% ($p<0.05$) and by 36% ($p<0.0001$) in the yeast-fermented group compared to control. No significant differences in triacylglycerol and total cholesterol levels in either plasma or liver were observed between the groups [Mauray 2009].

In a continuation of the experiment, apo E-deficient mice (n=40) were fed *ad libitum* for two weeks either a control diet or the same diet supplemented with 0.02% of the anthocyanin-rich extract. After two weeks plasma lipid and antioxidant capacity were evaluated and the global genomic analysis carried out using pangenomic microarrays. Anthocyanin supplementation significantly ($p<0.05$) reduced total-cholesterol (mmol /L) from 7.0 (control) to 5.6, whereas plasmatic antioxidant status remained unchanged. Genomic analysis identified 1,261 genes

in the aorta whose expression was modulated by the bilberry extract [Mauray 2012].

Further investigation of the anti-atherogenic effect of a bilberry extract (52% anthocyanins) on gene expression in the liver of apo E-deficient mice was carried out. Mice received for 2 weeks a standard diet supplemented with an anthocyanin-rich bilberry extract (0.02%). After a 2-week supplementation plasma total cholesterol (mmol /L) and hepatic triglyceride levels (mg /g) were significantly reduced ($p<0.05$ and $p<0.01$ respectively), while plasmatic antioxidant status remained unchanged. Transcriptional analysis showed that the expression of 2,289 genes was significantly altered, with over-expression of genes involved in bile acid synthesis and cholesterol uptake into the liver, but down-regulation of expression of pro-inflammatory genes [Mauray 2010].

Wound healing effects
Topical application of 5-10 mg of an anthocyanin-rich extract of bilberry fruit accelerated the healing of experimental wounds in rats [Curri 1976]. In another experimental model (healing delayed by prednisone) the same extract applied topically at concentrations of 0.5-2% for 3 days to skin wounds in rats promoted healing activity in comparison to prednisone-treated controls [Cristoni 1987].

Anti-inflammatory activity
The vasoprotective effect could also be responsible for anti-inflammatory activity exhibited by anthocyanins (50-500 mg/kg given orally) against paw oedema induced by irritant agents such as carrageenan, histamine or hyaluronidase [Bonacina 1973; Lietti 1976].

Mice sensitized by an epicutaneous application of 2,4,6-trinitro-1-chlorobenzene (TNCB; 100 µL of 1.1% v/v) to their shaved abdomen, were challenged with 10 µL/ ear of TNCB solution on day 0. TNCB was reapplied to each ear 3 times per week until day 16. Daily oral administration (0.4 or 2 g/kg b.w.) of a standardized bilberry extract (>25% anthocyanidins and >36% anthocyanins) significantly decreased ear swelling ($p<0.001$ vs control) and suppressed bouts of scratching associated with progressive and chronic allergic contact dermatitis ($p<0.001$ vs control). The lower dose of bilberry was more effective [Yamaura 2011].

In a further experiment using the same methodology the standardized bilberry extract (400 mg/kg b.w.) was administered orally for 4 weeks to BALB/c mice with allergic contact dermatitis induced by application of TNCB. Treatment with the anthocyanin-containing extract (non-heated) significantly attenuated the TNCB-induced increase in scratching behaviour compared to the vehicle ($p<0.05$). The anthocyanidin-rich (2-h heated) extract had no effect. The non-heated extract (300 µg/mL) resulted in significant inhibition of degranulation in RBL-2H3 mast cells ($p<0.05$) [Yamaura 2012].

Anti-ulcer/ gastroprotective activity
A standardized extract (corresponding to 25% of anthocyanidins) administered orally to rats at doses ranging from 25 to 200 mg/kg, showed antiulcer activity on ulcers induced by pyloric ligation, non-steroidal-antiinflammatory drugs (NSAIDs) and reserpine [Cristoni 1987].

Oral pretreatment of rats with C3G (4 and 8 mg/kg body weight) resulted in a 36 and 80% inhibition respectively ($P<0.05$) of ethanol-induced gastric lesions in comparison to control rats receiving only 80% ethanol. Pretreatment with C3G also inhibited elevation of lipid peroxide levels, and in gastric tissues significantly ($p<0.05$) increased glutathione levels and the activities of superoxide dismutase, catalase and glutathione peroxidase [Li 2008].

Pretreatment of mice (male ddY) with a bilberry extract (25% anthocyanidins) at doses of 10, 30 and 100 mg/kg, 1 h before HCl / ethanol administration, significantly inhibited gastric erosions in a dose-dependent manner ($p<0.01$ vs vehicle-treated mice) [Ogawa 2011].

Neuroprotection / Memory
Rats given intraperitoneal injections of bilberry anthocyanins (200 mg/kg/day) for 5 days had significantly more triiodothyronine (T3) in their brains than rats given the solvent (26% alcohol). Bilberry-treated animals showed superior memory, better vision and better control of sensory input [Saija 1990].

An aqueous suspension of lyophilised bilberries (equivalent to 3.2 mg anthocyanin/ kg/day) was given orally to rats for 30 days before first training (n=10 per group). Bilberries significantly enhanced short-term memory ($p<0.05$), but not long-term memory in the inhibitory avoidance task, and induced an increase in the number of crossings in the first exposure to the open field. In the radial arm maze test, anthocyanin-treated rats showed significant choice accuracy improvement ($p<0.05$) in the early sessions, an effect which became attenuated in later sessions [Ramirez 2005].

The effects of long-term supplementation with bilberry extract (2 g/kg of diet = 0.35 g anthocyanins/kg of food) and vitamin E (140 mg/kg of diet) were studied in young senescent-accelerated OXYS and Wistar rats. The role of oxidative stress on brain biomolecules such as protein carbonyls, lipid peroxides, reduced glutathione, α-tocopherol and superoxide dismutase as well as on learning ability was investigated. Bilberry extract and vitamin E improved cognitive deficits (tested by passive avoidance reaction retrieval) in OXYS rats. Supplementation with both vitamin E ($p= 0.008$) and bilberry extract ($p=0.002$) decreased lipid peroxides in rat brains. Bilberry extract significantly decreased MDA level only in OXYS rat's brain ($p=0.048$), while vitamin E significantly decreased MDA levels in both Wistar and OXYS rats, when compared with their respective controls [Kolosova 2006].

A bilberry extract was administered orally to mice (n=9; 100 mg/kg b.w.) for 7 days. Psychological stress was assessed by whisker removal which is known to increase both protein carbonyl formation and lipid peroxidation in the brain, heart, kidney and liver. Treated mice showed less lipid peroxidation in all these tissues. The stress-induced shift of dopamine in the brain was almost completely suppressed. [Rahman 2008].

Chemopreventive activity
Bilberry extracts were assessed for their effects on multiple biomarkers of azomethane-induced colon cancer in male rats which were fed *ad libitum* for 14 weeks on a control diet or one supplemented with bilberry (containing 3.85 g monomeric anthocyanins / kg of diet). Total colonic aberrant crypt foci (ACF) were reduced ($p<0.05$) compared with the control. The number of large ACF was also reduced ($p<0.05$) and colonic cellular proliferation was decreased. Bilberry-fed rats had lower COX-2 mRNA gene expression. High levels of faecal anthocyanins and increased faecal mass and moisture were found, as well as a significant reduction ($p<0.05$) in faecal bile acids [Lala 2006].

Apc^{Min} mice, a genetic model of human familial adenomatous polyposis, ingested C3G or a standardised bilberry extract (40% anthocyanins) at 0.03, 0.1 or 0.3% in the diet for 12 weeks. Ingestion of the highest doses of C3G and the bilberry extract showed a significant decrease in intestinal adenomas by 45%

($p<0.001$) or 30% ($p<0.05$) respectively compared to controls [Cooke 2006].

Multiple Intestinal Neoplasia/+ mice were fed modified high fat diets containing 10% freeze-dried bilberries (5.53 g total anthocyanins, 0.104 g total flavonols /kg diet) or a similar berry-free diet as control for 10 weeks. The berry diet significantly inhibited the formation of intestinal adenomas in the distal small intestine, as indicated by a 15-30% reduction in tumour cell number ($p<0.05$) [Misikangas 2007].

The effect of C3G on xenograft growth of human lung carcinoma cell line A549 was evaluated. Nude mice were treated intraperitoneally with either PBS or C3G (9.5 mg/kg) three times per week beginning 2 days after s/c tumour cell implantation. C3G-treated mice showed a ~50% reduction in tumour size, compared to control animals ($p<0.02$) and inhibited tumour metastasis [Ding 2006].

Immunostimulation / myelo- and cyto-protective activity
A single injection of 5-fluorouracil (5-FU) at 200 mg/kg into C57BL/6 mice induced severe peripheral erythrocytopenia, thrombocytopenia and leucopenia as well as hypocellularity of the spleen and bone marrow. Oral administration of 500 mg/kg of an anthocyanin-rich bilberry extract for 10 days significantly increased the number of red blood cells, neutrophils and monocytes in peripheral blood to 1.2-fold, 9-fold and 6-fold respectively, compared to 5-FU alone ($p<0.05$ - 0.001). The hypocellularity of the spleen and bone marrow caused by 5-FU was also distinctly alleviated [Choi 2007].

Pharmacological studies in humans

In a double-blind, placebo-controlled study involving 40 healthy subjects the activity of an anthocyanin-rich extract, administered orally at 240 mg daily for 3 months, was evaluated for pupillary movements through examination of the direct photomotor reflex. The study demonstrated a more efficient pupillary photomotor response after administration of the extract compared to placebo [Vannini 1986].

Young males with good vision, selected for a study using a double-blind, placebo-controlled, cross-over design, received 160 mg of bilberry extract (25% anthocyanins) (n=7) or placebo (n=8) three times daily for 21 days, followed by a one-month washout period and the second three-week treatment period. After the three-month study no difference in night visual acuity or night contrast sensitivity were found between placebo and test subjects [Muth 2000].

In a parallel-design, placebo-controlled clinical trial the effect of a purified anthocyanin preparation (150 mg, equivalent to 100 g fresh bilberries, twice daily for 3 weeks) was studied in healthy adults (n=120). In the anthocyanin group, changes were observed in (i) the NF-κB-controlled pro-inflammatory chemokine IL-8, (ii) RANTES (regulated upon activation, normal T cell expressed and secreted) and (iii) IFNα (an inducer of NF-κB activation) (45, 15 and 40% decreases from baseline, respectively) relative to those in the placebo group (20, 0 and 15% decreases from baseline, respectively) ($p<0.05$). Similarly, changes in IL-4 and IL-13, cytokines that mediate pro-inflammatory responses and induce NF-κB activation, were found in the test group (60 and 38% decreases from baseline respectively) compared with those in the placebo group (4 and 6% decreases) ($p=0.056$ and $p=0.089$, respectively) [Karlsen 2007].

Platelet aggregation was inhibited *ex vivo* in blood taken from healthy volunteers after oral administration of bilberry extract (480 mg/day; standardized to 36% anthocyanins) for 30-60 days [Pulliero 1989]. Purified anthocyanins and *in vivo* metabolites of polyphenols were also found to have anti-thrombotic properties [Rechner 2005].

Clinical Studies

Ophthalmic disorders

A systematic review of 30 relevant trials with bilberry anthocyanins on night vision, 12 of which were placebo-controlled, concluded that "negative outcome was associated with more rigorous methodology but also with lower dose level and extracts from geographically distinct sources that may differ in anthocyanoside composition. The hypothesis that bilberry anthocyanosides improve normal night vision is not supported by evidence from rigorous clinical studies. However when all studies are taken together (controlled and un-controlled trials with bilberry anthocyanins, controlled trials with related anthocyanins and evidence from animal studies), a sizeable body of positive auxiliary evidence exists for the potential therapeutic role of bilberry" [Canter 2004; Lee 2005].

Daily treatment of 14 patients suffering from tapetoretinal degeneration with 3 x 150 mg of a bilberry fruit extract resulted in an improvement in light sensitivity of the retina starting from the second day of treatment and remaining almost constant during the 3-month treatment period [Zavarise 1968].

Patients with glaucoma (n=8) were given a single dose (800 mg) of a standardized bilberry extract (25% anthocyanins). Evaluation using electroretinography showed improvements [Caselli 1985].

The efficacy of a standardized extract (320 mg/day) was evaluated in 40 patients with refractory defects. Accurate ocular and electrofunctional examinations showed a significant increase in the flash electroretinogram amplitude in medium ($p=0.002$) and high myopia ($p=0.008$), indicating an improvement in retinal sensitivity [Spadea 1991].

In another study, daily administration of 320 mg of the extract for 3 months to 26 myopic patients resulted in improvement of electrophysiological functions [Contestabile 1991].

Oral administration of a standardized extract of bilberry fruit at 480 mg/day for 180 days to 10 patients with type II diabetes mellitus and non-proliferative retinopathy resulted in improvement of the diabetic retinopathy, with marked reduction or disappearance of retinal haemorrhages [Orsucci 1983].

In a double-blind, placebo-controlled study, 40 patients with diabetic or hypertensive retinopathy were treated with 320 mg of a standardized extract of bilberry fruit or placebo daily for 30 days. An improvement in ophthalmoscopic and angiographic patterns was observed in 77-90% of the verum patients [Perossini 1987].

In another placebo-controlled study, involving 40 patients with diabetic retinopathy at a relatively early phase, a standardized extract of bilberry fruit administered at 320 mg/day for 12 months promoted the regression of hard exudates, which is considered a reliable index of altered permeability [Repossi 1987].

An open trial of bilberry extract (standardized to 25% anthocyanins; 80-160 mg three times daily for 4 weeks) was conducted on 31 patients with retinal pathology from various causes; diabetic (n=20); retinitis pigmentosa (n=5); macular degeneration (n=4) and haemorrhagic retinopathy from anticoagulant therapy (n=2). Reduced vascular permeability

and incidence of haemorrhage was reported in all patients, especially those with diabetic retinopathy [Scharrer 1981].

In a double-blind study, 14 diabetic and/or hypertensive outpatients with vascular retinopathy underwent therapy with bilberry anthocyanidins (160 mg twice daily) or placebo (n=20) for 1 month. At the end of the month placebo patients received the active for an additional month. Ophthalmoscopic and fluoroangiographic findings obtained before and after treatments showed improvements ranging from 77 to 90% in anthocyanin-treated patients [Bravetti 1989].

Twenty-two subjects (14 males, 8 females; age range 23-59) with self-reported symptoms of dry eye were assessed at baseline by the Ocular Surface Disease Index (OSDI), Tear Break-up Time and Schirmer's test. Patients were assigned to either bilberry (80 mg orally, twice daily; no other details given) or placebo for 30 days. The bilberry group showed a statistically significant improvement ($p<0.01$). The mean OSDI baseline for bilberry patients was 22.8 ±11.0, with post-treatment values of 13.7 ± 8.5 ($p<0.01$), while baseline for placebo was 27.9 ± 26.8 with post treatment values of 19.6 ± 20.0 (p=n.s.) [Anderson 2011].

Peripheral vascular diseases
In 47 patients with lower limb varicose syndrome, oral treatment with bilberry fruit extract at 480 mg/day for 30 days led to improvements in objective symptoms such as limb oedema and dyschromic skin phenomena, and subjective symptoms such as heaviness, paraesthesia and pain [Ghiringhelli 1977].

Improvements in vessel fragility and objective symptoms, after administration of bilberry fruit extract at 480 mg/day for 30-180 days, have been confirmed in trials performed on 22 diabetic and dyslipidaemic patients [Passariello 1979], on 97 patients with complaints induced by stasis of the lower extremities such as prevaricose syndrome, primary varicosis and post-phlebitic syndrome [Tori 1980], and on 42 patients with severe arterio-sclerotic vascular disease of the lower limbs [Nuti 1980].

In a double-blind, placebo-controlled study performed on 47 patients with peripheral vascular disorders of various origins, a standardized extract of bilberry fruit (480 mg/day for 30 days) reduced subjective symptoms such as heaviness, paraesthesia and pain, and improved oedema and mobility of finger joints [Allegra 1982].

The efficacy of a standardized extract of bilberry fruit has been evaluated in two clinical studies, each in 15 patients with venous insufficiency who were treated orally with 480 mg/day for 2-4 months. Significant improvements in plethysmographic ($p<0.05$) and duoregional rheographic ($p<0.001$) observations were reported [Signorini 1983a, 1983b].

In 24 patients with chronic venous insufficiency, oral administration of 480 mg of an anthocyanin-rich extract of bilberry fruit daily for 60 days induced a decrease in the total time of drainage after reactive hyperaemia evaluated by the strain gauge technique [Corsi 1985].

The efficacy of the same extract (480 mg/day for 30 days) was further demonstrated in a single-blind, placebo-controlled study carried out in 60 patients with different stages of venous insufficiency; this study showed significant activity of the extract ($p<0.01$ to $p<0.001$) on subjective parameters, namely feeling of pressure in the lower limbs and muscle cramps as well as oedema and leg and ankle girth [Gatta 1988].

Significant improvements in subjective symptoms ($p<0.01$) and reductions in oedema and capillary fragility were observed in 54 cases of phlebopathies induced by stasis during pregnancy after oral administration of 320 mg of extract daily for 60-90 days [Grismondi 1980].

Cardiovascular health
Unmedicated subjects with cardiovascular risk factors consumed berry (n = 35) or control products (n=36) for 8 weeks in a single-blind, randomized, placebo-controlled intervention trial. Mean daily intake from berry products was 837 mg polyphenols, of which 275 mg anthocyanins were from fresh bilberries (100 g). Berry consumption inhibited platelet function as measured with a platelet function analyser (using collagen and ADP as platelet activator) [changes: 11% and -1.4% in the berry and control groups, respectively; p=0.018, analysis of covariance]. Serum HDL-cholesterol concentrations increased significantly more (p=0.006, analysis of covariance) in the berry than in the control group (5.2% and 0.6%, respectively), but total cholesterol and triacylglycerol concentrations remained unchanged. Systolic blood pressure decreased significantly (p=0.050, analysis of covariance); the decrease mostly occurred in subjects with high baseline blood pressure (7.3 mm Hg in highest tertile; p=0.024, analysis of covariance). Polyphenol and vitamin C concentrations in plasma increased, whereas e.g. folate, tocopherols, sodium and potassium were unaffected [Erlund 2008].

Intake of anthocyanins (160 mg twice daily; cyanidin glycosides 33% with delphinidin glycosides 58%) for 12 weeks by subjects with elevated blood lipids (n=120, age 40-65 years) was compared with placebo in a double-blind, randomised, placebo-controlled trial. Anthocyanin consumption increased HDL-cholesterol concentrations (13.7% and 2.8% in the anthocyanin and placebo groups, respectively; $p<0.001$) and decreased LDL-cholesterol concentrations (13.6% and -0.6% in the anthocyanin and placebo groups, respectively; $p<0.001$). Cellular cholesterol efflux to serum increased more in the anthocyanin group than in the placebo group (20% and 0.2%, respectively; $p<0.001$). Anthocyanin intake decreased the mass and activity of plasma cholesteryl ester transfer protein (CETP) by 10.4% and 6.3% respectively, in the anthocyanin group and by -3.5% and 1.1% respectively in the placebo group ($p<0.001$). In the anthocyanin group, the change in HDL cholesterol was negatively correlated with the change in CETP activity (r_s=-0.33). The change in LDL cholesterol was positively correlated with the change in CETP mass activity (r_s=0.354). The change in cellular cholesterol efflux to serum was positively correlated with the change in HDL cholesterol activity (r_s=0.485) [Qin 2009].

Anti-inflammatory activities
In a randomized controlled trial, subjects at elevated risk of cardiovascular disease consumed either fresh bilberry juice diluted to 1 litre with water (n=31) or 1 litre of water (n=31) for 4 weeks. Participants in the test group consumed 330 mL bilberry juice /day. At the end of the intervention period plasma concentrations of inflammatory mediators showed C-reactive protein (CRP), interleukin (IL)-6, IL-15 and monokine induced by INF-γ (MIG) were significantly decreased in the bilberry group (p=0.027, p=0.037, p=0.008 and p=0.047, respectively [Karlsen 2010].

In another randomized controlled trial, subjects with features of metabolic syndrome were given either a diet with added bilberries equivalent to 400g fresh berries per day (n=15) or their normal diet alone (control group; n=12) for 8 weeks. Bilberry supplementation decreased serum high-sensitivity C-reactive protein, IL-6, IL-12 and LPS concentrations. An "inflammation score" based on changes of hsCRP, IL-6, IL-12 and LPS was significantly different between the groups (p=0.024) with the bilberry group showing decreased inflammation [Kolehmainen 2012].

Other effects
Colorectal cancer patients (n=25) scheduled to undergo resection of primary tumour or liver metastases each received 1.4, 2.8 or 5.6 g daily of a standardised bilberry extract (36% anthocyanins; containing 0.5, 1.0 or 2.0 g anthocyanins respectively) for 7 days before surgery. Colorectal tumour sections, obtained before and after intake of the bilberry extract, were stained for Ki-67 (mouse anti-human monoclonal antibody) or cleaved caspase-3 to determine proliferation of the tumour. In tumours from all patients receiving the bilberry extract the proliferation index (reflected by Ki-67 staining) showed a significant 7% reduction (p=0.003) compared with preintervention values. No significant decrease in tumour tissue proliferation was found in patients receiving 1.0 g and 2.0 g anthocyanins, while a significant 9% decrease (p=0.021) occurred in patients receiving 0.5 g anthocyanins [Thomasset 2009].

Overweight and obese women (n=110) were recruited into a study of randomized cross-over design to examine the effects of berries on variables of obesity-related diseases. Bilberries (100g daily, whole, frozen) were given for 33-35 days followed by a wash-out period of 30-39 days. Consumption of bilberries resulted in a statistically significant (p=0.041) decrease in waist circumference and a small decrease in weight (p=0.028). Significant decreases in vascular cell adhesion molecule (p=0.002) and TNF-α values (p=0.031) were also recorded [Lehtonen 2011].

Pharmacokinetic properties

Pharmacokinetics in animals

Absorption, distribution, metabolism and elimination
After intravenous or intraperitoneal administration of an anthocyanin-rich extract (equivalent to 25% of anthocyanidins) to rats at doses of 20-40 mg/kg or 25 mg/kg, respectively, anthocyanins were rapidly distributed to the tissues. Elimination occurred mainly in the urine (25-30% of the dose within 24 hours after administration) and to a lesser extent (15-20%) in bile [Lietti 1976].

After oral administration to rats of a single dose of 400 mg/kg, a standardized extract of bilberry fruit was rapidly absorbed from the gastrointestinal tract, reached a plasma concentration of C_{max} of 2.47 µg/mL after 15 min, and rapidly declined within 2 h [Morazzoni 1991].

A bilberry extract (containing 153.2 mg total anthocyanins/kg), with delphinidin galactoside as the main constituent (19.6 mg/kg), was administered to rats orally (400 mg/kg b.w.) or intravenously (5 mg/kg b.w.). After oral administration most anthocyanins rapidly appeared in the plasma and reached their maximum level at 15 min, except galactosides of petunidin, peonidin and malvidin that reached their maximum at 30 min. The bioavailability of individual anthocyanins was in the range 0.6 to 1.8%, and 0.93% as the anthocyanin mixture. After intravenous administration anthocyanins recovered in urine and bile during the first 4 h were only 30.8 and 13.4% respectively [Ichiyanagi 2006].

Oral administration of a bilberry extract to mice (dried, prepared from fresh berries; 100 mg/kg b.w.) resulted in a maximum plasma anthocyanin concentration (1.18 µM) after 15 min. Urinary excretion ceased by 24 h after a maximum between 0 and 6 h after administration. Total amount of anthocyanins excreted into the urine represented 1.88%. Malvidin-3-glucoside and -3-galactoside were the principal anthocyanins in the plasma 60 mins after administration. Maintenance of the mice for 2 weeks on a diet containing 0.5% of bilberry extracts resulted in a maximum anthocyanin plasma concentration of 0.26 µM. Anthocyanins were detected in the liver (605 pmol/g), kidneys (207 pmol/g), testes (149 pmol/g) and lungs (116 pmol/g), with the malvidin glycosides being the predominant anthocyanins. No anthocyanins were detected in the spleen, thymus, heart, muscle, brain, white fat or eyes [Sakakibara 2009].

Apc^{Min} mice ingested cyanidin-3-glucoside (C3G) or a bilberry extract (standardised to contain 40% anthocyanins) at 0.03, 0.1 or 0.3% in the diet (equivalent to 45, 150 or 450 mg/kg b.w./day) for 12 weeks. Anthocyanins were found in the plasma, the intestinal mucosa and urine. At 0.3% in the diet, anthocyanin levels were at the limit of detection in plasma, were 43 ng/g tissue for C3G and 8.1 ng/g tissue for the bilberry extract in the intestinal mucosa and 7.2 and 12.3 µg/mL (C3G and extract respectively) in the urine. Anthocyanin glucuronide and methyl metabolites were identified in the intestine and urine [Cooke 2006].

Fifteen minutes after oral supplementation of a mixture of 320 mg/kg b.w. C3G and 40 mg/kg b.w. cyanidin-3,5-diglucoside (Cy-dg), rats showed an increase to a maximum of 1563 µg (3490 nmol) of C3G/L and 195 µg (320 nmol) of Cy-dg/L in plasma and 0.067 µg (0.15 nmol) of C3G/g and a trace of Cy-dg together with methylated metabolites in the liver [Miyazawa 1999].

Pharmacokinetics in humans

A review of the data from human studies of cyanidins bio-availability shows that single doses of 188 – 3,570 mg total anthocyanins produced very low maximal plasma concentrations, of the range of 2.3 - 96 nM. The mean time to reach these concentrations was around 1.5 h. Most studies reported very low relative anthocyanin urinary excretions, ranging from 0.018 to 0.37%. Maximal urinary excretion was usually achieved in less than 4 h. Methylated derivatives, anthocyanidin glucuronide conjugates as well as anthocyanin glycoside glucuronides have been identified in urine or plasma [Galvano 2007].

All studies have shown that absorption is very low, with often less than 0.15% of the ingested dose appearing in the urine [McGhie 2003; McGhie 2007; Dreiseitel 2009].

Colorectal cancer patients (n=25) received 1.4, 2.8 or 5.6 g daily of a standardised bilberry extract containing 36 % w/w anthocyanins for 7 days. Anthocyanins, as well as methyl- and glucuronide metabolites were identified in plasma, colorectal tissue and urine, but not the liver [Thomasset 2009].

Thirty minutes after receiving a single oral dose of a mixture of 2.7 mg/kg b.w. C3G and 0.25 mg/kg b.w. cyanidin-3,5-diglucoside (Cy-dg), human adults (n=12, 20-29 years, 40-70 kg) had an average of 24 nM of C3G and traces of Cy-dg in plasma. Neither cyanidin aglycone, nor conjugated or methylated metabolites were found [Miyazawa 1999].

Healthy elderly women (n=4) having fasted overnight were given a single oral dose of 720 mg anthocyanins (cyanidin-3-glucoside and cyanidin-3-sambubioside). Maximum plasma concentrations of total anthocyanins varied from 55.3 to 168.3 nM, with an average of 97.4 nM, and were reached within 71.3 min (t_{max}). The elimination of plasma anthocyanins appeared to follow first-order kinetics. Half-life of cyanidin-3-glucoside is 97.3 min and cyanidin-3-sambubioside is 168.9 min. No anthocyanin glucuronides or sulphates were detected. The anthocyanins were excreted as glycosides in urine mostly during the first 4h (77.2 µg/h during the first 4 h and 13.4 during the second 4 h) [Cao 2001].

Adult males (n=3) received a dose of 721 mg cyanidin-3-glycosides. The cumulative concentration of total anthocyanins (parent and metabolites) detected in the serum (0-7 h) was 376.7 (nmol.h)/L, reaching a maximum concentration of 96.1 nM/L within 2.8 h. Parent anthocyanin glycosides represented only 32.0% of the total anthocyanins detected with 68% identified as glucuronidated and methylated derivatives. Total urinary excretion of anthocyanins over 24 h was 1072 µg, reaching a maximal excretion rate (203 µg/h) at 3.7 h [Kay 2005].

Preclinical safety data

Acute toxicity
Intraperitoneal and intravenous LD_{50} values of an anthocyanin-rich extract from bilberry fruit containing about 70% of anthocyanins were determined as 4.11 g/kg and 0.84 g/kg in the mouse, and 2.35 g/kg and 0.24 g/kg in the rat, respectively. No deaths were observed following oral doses of up to 25 g/kg in the mouse and 20 g/kg in the rat [Pourrat 1967].

Acute oral LD_{50} of an anthocyanin-rich berry extract (containing cyanidin, delphinidin, petunidin, malvidin) was greater than 5 g/kg in rats. Acute dermal LD_{50} was greater than 2 g/kg [Bagchi 2006].

Repeated dose and chronic toxicity studies
Treatment of rats for 90 days with the same extract at a daily dose corresponding to approximately five times the human clinical dose (i.e. 600 mg/day) did not produce any toxic effects [Pourrat 1967].

Mutagenicity and carcinogenicity
A bilberry extract (36% anthocyanins) did not show mutagenic activity in various tests of mutagenesis, with and without metabolic activation, and showed no teratogenic effect or influence on rat fertility [Eandi 1987].

Cytotoxicity to HaCaT keratinocytes was determined using a lactate dehydrogenase (LDH) leakage assay. Berry extracts (50 µg/mL) were added to the cells and after 24 h media were collected for assay. No significant cytotoxicity was noted with the bilberry extract (50 µg/mL) when compared to control [Yasmin 2003].

The effects of different concentrations of bilberry extract (containing 25% total anthocyanins) were studied using human corneal limbal epithelial cells (HCLEC). The extract (10^{-5} M) promoted cell growth to 120% compared with the control group ($p<0.05$) after 24 h and 48 h incubation. Cytotoxicity was not noted [Song 2010].

Clinical safety data

The safety of the bilberry extract (36% anthocyanins; mostly 160 mg twice daily for 1-2 months) was confirmed in a post-marketing surveillance study on 2295 subjects affected by: lower limb venous insufficiency (24.23%), states of fragility and altered permeability of the blood capillaries (21.51%), functional changes in retinal microcirculation (10.15%) and haemorrhoids (9.93%) [Eandi 1987].

Daily intake of 100 - 335 mg of anthocyanins was considered safe [Karlsen 2007]. Long-term oral administration in humans in doses equivalent to 180 mg/kg anthocyanins per day for six months produced no toxic effects [Eandi 1987].

In colorectal cancer patients, daily consumption of 5.6 g of a standardised bilberry extract (36% anthocyanins) for 7 days was well tolerated [Thomasset 2009].

Asymptomatic subjects with intraocular hypertension were given either a combination of two phenolic extracts from bilberry (80 mg, standardised to 36% anthocyanins) and French maritime bark (40 mg, standardised to 70% procyanidins) (n=20) twice daily or were not treated (n=18). During 2 months of treatment, no side effects were observed [Steigerwalt 2008]. In a further trial with this product, in patients (n=33) who received one tablet daily, no side effects occurred [Steigerwalt 2010].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

Front cover
Title page
Verso
Foreword and Preface
Notes for the Reader
Abbreviations
The monograph text
Back cover

Information on the member organizations and people involved in ESCOP's activities can be found on the website (www.escop.com):

Members of ESCOP

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ONONIDIS RADIX

2015

Restharrow Root

DEFINITION

Restharrow root consists of the dried roots of *Ononis spinosa* L.

The material complies with the monograph of the European Pharmacopoeia [Restharrow root].

CONSTITUENTS

Isoflavones including trifolirhizin, formononetin together with its 7-O-glucoside-6''-malonate and 7-O-glucoside (= ononin) [Háznagy 1978; Köster 1983], biochanin A 7-O-glucoside, medicarpin and related compounds [Fujise 1965; Háznagy 1978; Köster 1983; Pietta 1983; Dannhardt 1992]. Triterpenes, notably α-onocerin [Háznagy 1978; Rowan 1972; Spilková 1982; Pauli 2000, Daruhazy 2008]; phytosterols, especially β-sitosterol [Köster 1983; Rowan 1972, Daruhazy 2008]; deoxybenzoines, especially ononetin [Straub 2013]; phenolic acids [Luczak 1991]; tannins [Dedio 1977a]; minerals [Steinegger 1992] and about 0.02% of essential oil containing mainly *trans*-anethole, carvone, menthol and aromatic hydrocarbons [Hilp 1975; Dedio 1977b; Hesse 1977].

CLINICAL PARTICULARS

Therapeutic indications
Irrigation of the urinary tract, especially in cases of inflammation and renal gravel, and as an adjuvant in treatment of bacterial infections of the urinary tract [Schilcher 1987, 1990; Kartnig 2007; Weiß 2009].

Posology and method of administration

Dosage

Adults: An infusion of 2-3 g of dried material (the mixture being strained after 20-30 minutes) two to three times per day; equivalent preparations [Wichtl 2009].

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contra-indications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

MONOGRAPHS

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

Diuretic activity

In vivo experiments
Four preparations of restharrow (presumed to be from the root) were administered intragastrically to different groups of 4 rats, each dose being equivalent to 0.3 g of root and including 20 mL of water. The controls were water or theophylline (5 mg/kg), administered to the same rats several days later. The volumes of urine collected over a 5-hour period following administration of the respective preparations were: dried methanolic extract (rich in flavonoids) 19.9 mL, ash (rich in minerals, especially potassium) 18.7 mL, a mixture of methanolic extract and ash 20.9 mL, and aqueous infusion 21.4 mL, compared to 15.1 mL for water and 17.9 mL for theophylline. Corresponding amounts of sodium, determined by atomic absorption spectrophotometry in the urine, were 20, 32, 21 and 24 mg, compared to 6 and 16 mg with water and theophylline respectively. The potassium figures were 95, 79, 66 and 62 mg, compared to 44 and 61 mg with water and theophylline. These results demonstrated moderate diuretic ($p<0.001$) and saluretic activity, particularly natriuretic, in all cases higher than that of theophylline at 5 mg/kg. It was concluded that the diuretic activity of restharrow root was caused by its content of potassium salts and flavonoid glycosides [Rebuelta 1981].

An ethanolic extract (not defined) at a dose corresponding to 2 g/kg b.w. significantly increased urinary volume in rats by 103% ($p<0.05$) compared to saline. No influence was observed on sodium or potassium elimination. Intraperitoneal administration did not show any diuretic effect at doses of drug up to 500 mg/kg [Bolle 1993].

Older studies gave the following results: an infusion from restharrow root administered orally to rabbits increased the urinary output by approx. 26% [Vollmer 1937a]; in mice an increase of urinary output and chloride excretion was demonstrated [Vollmer 1937a], while in rats the excretion of urea and chloride increased after oral administration [Vollmer 1937b].

After oral administration to rats, infusions of the root caused slight diuresis (average of 12%) and decoctions an antidiuretic effect of 7-20%. In these studies the aqueous residue after steam distillation showed an antidiuretic effect of 7-16 % depending on the duration of distillation, whereas 0.5-1.0 mL of the essential oil obtained by steam distillation (2-4 hours) produced a diuretic effect [Hilp 1976].

Other effects

In vitro experiments
A methanolic restharrow root extract (6:1) was found to inhibit 5-lipoxygenase selectively with an IC_{50} of 7.8 µg/mL. Medicarpin, isolated from the extract, inhibited leukotriene B_4 formation with an IC_{50} of 6.7 µM [Dannhardt 1992].

Ononetin showed a high potency in blocking the melastin-related Transient Receptor Potential cation channel, subfamily M, member 3 (TRMP3 channels) expressed in neuronal and non-neuronal tissues of the human body [Straub 2013].

In vivo experiments
In the phenylquinone writhing test in mice, an ethanolic restharrow root extract (not further defined) reduced reaction to pain by up to 80% at doses of 100 and 500 mg/kg b.w. after intraperitoneal administration, while no effect was observed after oral administration. No analgesic effects were observed in the hot plate test in mice after oral or intraperitoneal administration of the extract [Bolle 1993].

In the carrageenan-induced rat paw oedema test, the same extract significantly reduced oedema by a maximum of 46% after 3 hours ($p<0.05$) at an intraperitoneal dose corresponding to 500 mg of restharrow root per kg b.w., while no significant effects were observed at 100 mg/kg [Bolle 1993].

Pharmacokinetic properties
No data available.

Preclinical safety data
An ethanolic extract (not further defined), administered orally or intraperitoneally at a daily dose corresponding to 2 g/kg b.w. for 14 days to rats or mice did not cause any visible toxic effects [Bolle 1993].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ORTHOSIPHONIS FOLIUM 2014

Java Tea

DEFINITION

Java tea consists of the fragmented, dried leaves and tops of stems of *Orthosiphon stamineus* Benth. (*O. aristatus* Miq.; *O. spicatus* Bak.). It contains not less than 0.05% of sinensetin ($C_{20}H_{20}O_7$; M_r 372.4) (dried drug).

The material complies with the monograph of the European Pharmacopoeia [Java tea].

CONSTITUENTS

Up to 12% of minerals with approx. 3% of potassium [Van der Veen 1979; Fintelmann 2002; Schilcher 2010].
Approx. 0.2% of lipophilic flavones including sinensetin and isosinensetin [Bombardelli 1972; Schneider 1973; Wollenweber 1985; Malterud 1989; Pietta 1991; Sumaryono 1991; Proksch 1992; Takeda 1993; Olah 2003; Merfort 2007; Wichtl 2009], flavonol glycosides [Sumaryono 1991; Proksch 1992].
Rosmarinic acid (0.1-0.5%) [Gracza 1984; Lamaison 1990; Proksch 1992; Takeda 1993] and other caffeic acid depsides [Sumaryono 1991; Proksch 1992; Olah 2003], inositol [Van der Veen 1979] and up to 0.7% of essential oil with mainly sesquiterpenes [Schut 1986; Merfort 2007].
Pimarane, isopimarane and staminane diterpenes, e.g. the highly oxygenated orthosiphols [Masuda 1992a, 1992b; Takeda 1993; Shibuya 1999a; Stampoulis 1999a, 1999b; Ohashi 2000a, 2000b; Tezuka 2000, Awale 2001, 2002, 2003a, 2003b, 2003c; Nguyen 2004], triterpenes such as ursolic and oleanolic acid [Proksch 1992; Tezuka 2000] and chromenes such as methylripariochromene A [Guérin 1989; Shibuya 1999b; Ohashi 2000b].

CLINICAL PARTICULARS

Therapeutic indications

Irrigation of the urinary tract, especially in cases of inflammation and renal gravel, and as an adjuvant in the treatment of bacterial infections of the urinary tract [Proksch 1992; Premgamone 2001; Fintelmann 2002; Jänicke 2003; Bradley 2006; Merfort 2007; Premgamone 2007; Kieley 2008; Schilcher 2010].

Efficacy in these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adults: An infusion of 2-3 g of dried material in 150 mL of water two to three times per day; equivalent preparations [Van Hellemont 1988; Premgamone 2001; Fintelmann 2002; Jänicke 2003; Bradley 2006; Premgamone 2007; Wichtl 2009; Schilcher 2010].

Method of administration
For oral administration.

Duration of administration
If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.

Special warnings and special precautions for use
Java tea should not be used in patients with oedema due to impaired heart and kidney function [Wichtl 2009].

Interaction with other medicaments and other forms of interaction
None reported.

E/S/C/O/P MONOGRAPHS

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antibacterial activity
Bacteriostatic [Van der Veen 1979; Chen 1989] and fungistatic [Wolters 1966] activity has been demonstrated, and the bacteriostatic activity has been attributed to caffeic acid derivatives, particularly rosmarinic acid [Proksch 1992].

Receptor-binding activity
An aqueous (1g/100 ml) and a methanolic (5:1) extract showed dose-dependent inhibitory activity on ^{125}I-TGF-β_1 binding to its receptor in Balb/c 3T3 cells. The inhibition was 42.3% at a concentration of 10 µL/mL of the aqueous extract. Complete inhibition was observed with 100 µL/mL of the aqueous and 200 µL/mL of the methanolic extract. Ursolic and oleanolic acid inhibited binding of ^{125}I-TGF-β_1 to its receptor with IC_{50} values of 6.9 ± 0.8 and 21.0.± 2.3 µM, respectively [Yoshimura 2003].

Antagonistic effects on the adenosin A_1 receptor (which might cause diuretic and saluretic effects) have been shown for seven flavonoids obtained by bioassay-guided fractionation of an 80% methanol extract [Yuliana 2009].

Enzyme-inhibiting effects
A hexane extract (not further specified) inhibited ouabain-sensitive activity of Na^+/K^+-ATPase from rat brain with an IC50 of 8.5 µg/mL (compared to ouabain with an IC_{50} of 1.3 µg/mL) indicating a diuretic potential [Ngamrojanavanich 2006].

Effects on lipoxygenase activity
Various isolated lipophilic flavones inhibited 15-lipoxygenase [Lyckander 1992]. In another study, flavonoids isolated from Java tea prevented inactivation of soybean 15-lipoxygenase. The compounds with the strongest enzyme-stabilizing effects, 5,7,4′-trimethylapigenin, eupatorin and 5,7,3′,4′-tetramethylluteolin, gave 50% protection at concentrations of 2.0, 2.4 and 4.3 µM, respectively [Lyckander 1996].

Antioxidant effects
Aqueous leaf extracts (1:10) containing total phenols between 6.54 and 9.04 mg/g dry weight showed antioxidant activity in the β-carotene/linoleic acid system; butylated hydroxytoluene and quercetin were used as references. The relative inhibition at a dose of 0.2 mL of the extracts as compared to control (distilled water) varied between 41.29% and 70.13% depending on the origin of the plant material, it was 58.42% for BHT and 72.27% for quercetin, respectively [Akowuah 2003].

A lyophilised extract (16:1; 50% methanol) showed a concentration-dependent antioxidant activity by scavenging DPPH radicals with an IC_{50} value of 0.28 mg/mL. The total antioxidant activity of 1 mg/ml of the extract was 2.73 mM Trolox equivalents. The same extract inhibited Fe^{3+}-induced lipid peroxidation in rat liver homogenate in a dose-dependent manner with an IC_{50} of 0.17 mg/ml [Yam 2007].

An ethanolic extract (10:1) demonstrated marked inhibitory effects on LPS-stimulated NO production (28.7 ± 2.0 nM) at a dose of 25 µg/mL, and on PGE_2 production in LPS-stimulated RAW 264.7 cells (6.35 ± 0.76 ng/mL) at the same dose [Hsu 2010].

A 60% methanolic extract and its fractions (hexane, chloroform, ethyl acetate, *n*-butanol and water) revealed DPPH scavenging activities with IC_{50} values of 16.7 ± 1.5 µg/mL, 126.2 ± 23 µg/mL, 31.3 ± 1.2 µg/mL, 15.3 ± 2.3 µg/mL, 13.6 ± 1.9 µg/mL and 23.0 ± 3.2 µg/mL, respectively [Abdelwahab 2011].

Nitric oxide inhibiting effect
Highly oxygenated isopimarane-type diterpenes (e.g. orthosiphols, deacetylorthosiphols and siphonols) isolated from a methanolic extract inhibited NO production in LPS-activated macrophage-like J774.1 cells. Some of them were more potent than L-NMMA (N^{γ}-monomethyl-L-arginine) used as positive control [Awale 2003a, 2003b, 2003c, 2003d; Nguyen 2004].

Cytoprotective effects
A 60% methanolic extract and its fractions (hexane, chloroform, ethyl acetate, *n*-butanol and water) showed significant protective effects against hydrogen peroxide-induced apoptosis on MDA-M231 epithelial cells at concentrations between 62.5 µg/mL and 500 µg/mL ($p<0.05$ and 0.01, respectively). IC_{50} values ranged between 23.1 ± 3.2 µg/mL and 56.4 ± 6.0 µg/mL at a concentration of 62.5 µg/mL, between 20.6 ± 0.9 µg/mL and 84,8 ± 4.0 µg/mL at a concentration of 125 µg/mL, between 22.47 ± 1.6 µg/mL and 100.0 ± 16.5 µg/mL at a concentration of 250 µg/mL and between 25.9 ± 1.0 µg/mL and 100.0 ± 27.8 µg/mL at a concentration of 500 µg/mL [Abdelwahab 2011].

Antiproliferative effects
Isolated highly oxygenated diterpenes (orthosiphols A, B, K, L, M and N as well as norstaminone A and neoorthosiphol A) displayed mild antiproliferative activity on liver metastatic murine colon 26-L5 carcinoma and human HT-1080 fibrosarcoma cell lines (ED_{50} between 12.8 and 63.1 µg/mL and between 18.6 and <100 µg/mL, respectively). Isolated flavones showed more potent activity on these cell lines, with the strongest being 5,6-dihydroxy-4′7-dimethoxyflavone with an ED_{50} value of 2.3 and 3.0 µg/mL, respectively [Awale 2001]. In a similar experiment, orthosiphols D, E, O, P and Q as well as nororthosiphonolide A and orthosiphonone A showed the same effects [Awale 2002]. Isolated diterpenes and flavonoids showed weak cytotoxicity towards murine colon carcinoma 26-L5 cells [Tezuka 2000].

In the enzyme-linked immunosorbent assay a 50% ethanolic extract significantly reduced the vascular endothelial growth factor level (211 ± 0.26 pg/mL cell lysate) compared to control (378 ± 5 pg/mL). In various angiogenesis models the extract caused inhibition of human umbilical vein endothelial cell proliferation at concentrations between 6.25 and 100 µg/mL with an IC_{50} of 48.23 µg/mL compared to vincristine with an IC_{50} 0.13 µg/mL [Ahamed 2011].

Effects on metabolic enzymes
The inhibitory effects of a 50% methanolic extract on various isoforms of UDP-glucuronyl transferases (UGT) was examined using 4-methylumbelliferone as substrate. At doses between 0.01 and 50 µg/mL, the extract inhibited the activities of most

of the isoforms in a dose-dependent manner [Ismail 2010].

A petroleum ether extract competitively inhibited CYP2C19 activity with an IC_{50} of 67.1 µg/mL (K_i = 41.5 µg/mL), eupatorin gave a mixed type inhibition with an IC_{50} of 12.1 µg/mL (K_i = 7.1 µg/mL) [Pan 2011a]. The effects of four different extracts (petroleum ether, dichloromethane, methanol, water) as well as three constituents (sinensetin, eupatorin, rosmarinic acid) were examined in a further experiment. While CYP2C9 was not inhibited at all, CYP2D6 was inhibited only by eupatorin (IC_{50} = 3.8 µg/mL; K_i = 3.5 µg/mL). All extracts as well as rosmarinic acid and sinensetin were found to not significantly inhibit CYP2D6 activity. With regard to CYP3A4, the aqueous and methanolic extracts and sinensetin did not exhibit significant modulatory effects. However, CYP3A4 was non-competitively inhibited by the petroleum ether extract and eupatorin (IC_{50} = of 46.3 and 5.0 µg/mL, respectively; K_i = 44.9 and 3.2µg/mL, respectively). Additionally, CYP3A4 was moderately inhibited by the dichloromethane extract in a mixed-type mode (IC_{50} = 96.5 µg/mL, K_i = 93.7 µg/mL). The effect of rosmarinic acid was also moderate with an IC_{50} of 86.9 µg/mL and a K_i of 118.3 µg/mL [Pan 2011b].

Ex vivo experiments

Suppression of contractile force
Various substances isolated from the leaves of Java tea had a concentration-dependent suppressive effect on contractile responses in endothelium-denuded rat thoracic aorta strips. IC_{50} values were between 1.01×10^{-1} µmol/ml for acetovanillochromene and 8.08×10^{-3} µmol/ml for tetramethylscutellarein; nifedipine as a positive control gave a value of 1.79×10^{-5} µmol/ml [Ohashi 2000a, 2000b]. Methylripariochromene A at doses of 1.1×10^{-2} mM, 3.8×10^{-2} mM and 1.1×10^{-1} mM decreased the maximum contractions caused by Ca^{2+} at 30 mM to 73.8%, 47.0% and 21.0% respectively [Ohashi 2000b; Matsubara 1999].

After cumulative applications of 3.8×10^{-2} mM and 1.2×10^{-1} mM to spontaneously beating isolated guinea pig atria, methylripariochromene A significantly suppressed the contractile force by 18.8% ($p<0.05$) and 54.7% ($p<0.01$) respectively, without significantly reducing the beating rate [Ohashi 2000b; Matsubara 1999].

Hypoglycaemic effects
In perfused rat pancreas, the extract did not increase insulin secretion in the presence of 5.5 mM glucose, but 100µg/ml extract did potentiate glucose-induced insulin secretion [Sriplang 2007].

Gastroprotective effects
Oral administration of a 50% methanolic extract to rats at doses between 250 and 1000 mg/kg exhibited dose-dependent inhibition of ethanol-induced lipid peroxidation in the isolated stomach between 16.3 and 52.9 % ($p<0.1$ to <0.001), and at doses between 0.0625 and 1 mg/mL inhibited $FeCl_2$-induced lipid peroxidation ($p<0.05$) with an ED_{50} of 0.157 mg/mL [Yam 2009].

In vivo experiments

Diuretic activity
The volume of urine and excretion of electrolytes (K^+, Na^+, Cl^-) were increased by intravenous infusion into dogs of a 50% ethanolic extract at 18.8 mg/kg/min [Chow 1979]. Oral administration to rats of a lyophilized aqueous extract at 750 mg/kg b.w. enhanced ion excretion (K^+, Na^+, Cl^-) to a level comparable to that obtained with 100 mg/kg furosemide, but no aquaretic effect was observed [Englert 1992].

Although it is not yet clear which are the active compounds [Proksch 1992], the diuretic effect could be partially due to the potassium content of Java tea [Van der Veen 1979; Englert 1992] as well as to the flavones sinensetin and 3'-hydroxy-5,6,7,4'-tetramethoxyflavone, which exhibited diuretic activity in rats after intravenous administration of 10 mg/kg b.w. [Schut 1993].

Aqueous (5:1) and ethanolic (7:1, ethanol 70%) spray-dried extracts of Java tea were administered by gavage to male rats as single doses at two levels: the aqueous extract at 18.0 mg/kg and 180 mg/kg, the ethanolic extract at 13.5 mg/kg and 135 mg/kg. Each extract was given to 5 rats, a further 5 rats receiving water as controls, and urine was collected over a period of 6 hours. After all doses the urine volume was between 2.99 and 3.36 ml/100 g rat, significantly higher ($p \leq 0.05$) than that of controls (2.15 mL). With both doses of the aqueous extract, a significant increase ($p=0.009$) in sodium elimination was observed (0.1-0.12 mEq/ 100 g rat) compared to controls (0.05 mEq). The higher doses of aqueous and ethanolic extracts significantly ($p=0.009$ and $p=0.02$ respectively) increased chloride elimination (0.11 and 0.09 mEq/100g rat) compared to controls (0.07 mEq). No significant changes were observed in elimination of potassium or urea [Casadebaig-Lafon 1989].

A hydroethanolic extract was administered intraperitoneally to 13 male rats as a single dose of 50 mg/kg b.w.; a control group of 28 rats received hypotonic saline solution. Another group of 10 rats received hydrochlorothiazide at 10 mg/kg b.w. After 8 hours the urine volume from rats treated with the extract was significantly higher ($p<0.001$) than that of the controls and was comparable to the volume after hydrochlorothiazide treatment [Beaux 1998].

Two tinctures (1:5; ethanol 50% and 70%) were tested in male Wistar rats having a minimal diuresis of 40 % in 2 hours after 24 hours abstinence of water. The tinctures at a dose of 700 mg/kg b.w. each were compared to furosemide 30 mg/kg b.w. and control (water), urine was collected for 24 hours. Urine output was found to be 41 and 29 ml/24h/kg rat, respectively, for the tinctures compared to furosemide (81 mL) and water (32 mL). Sodium saluresis was 5.7 and 4.6 mEq/24h/kg b.w. for the tinctures compared to furosemide (4.5 mEq/24h/kg b.w.) and water (3.6 mEq/24h/kg b.w.); potassium saluresis 1.1 and 0.9 mEq/24h/kg b.w. for the tinctures compared to furosemide (2.5 mEq/24h/kg b.w.) and water (0.6 mEq/24h/kg b.w.) The quantity of uric acid was 7.0 and 5.0 mg/24h/kg b.w. for the tinctures as compared to water (3.7 mg/24h/kg b.w.) [Olah 2003].

After oral administration of two different extracts (3.3:1, methanol 100% and 2.8:1, methanol 50%) to Sprague-Dawley rats at 2 g/kg b.w., sodium and potassium excretion increased significantly ($p<0.05$ and <0.01) in the first 8 hours of treatment. The effect was comparable to hydrochlorothiazide (10 mg/kg). Repeated administration of the extracts for 7 days at a dose 0.5 g/kg b.w. led to a significant increase in urine volume ($p<0.01$) and electrolyte excretion ($p<0.05$ and <0.01). Administration of 0.5, 1 and 2 g/kg b.w. of the extracts as well as allopurinol (50 mg/kg b.w.) significantly reduced ($p<0.05$) the serum urate levels in hyperuricaemic rats after 6 hours [Arafat 2008].

An aqueous extract (9:1) at doses of 5 and 10 mg/kg b.w. was administered orally to Sprague-Dawley rats. Furosemide and hydrochlorothiazide (each at a dose of 10 mg/kg b.w.) were used as controls. Urine volume, pH, density and electrolytes were determined every hour for 4 hours. The total urine volume after 4 hours was 0.85 and 1.87 mL for the extract doses, and 3.06 and 2.55 mL for furosemide and hydrochlorothiazide respectively.

The extract increased potassium excretion considerably more than the reference substances. No significant changes in urine pH and density were observed after administration of the extract [Adam 2009].

Methylripariochromene A isolated from Java tea was suspended in 0.5% Tween 80 and administered orally to 5 rats at three dose levels (25, 50 and 100 mg/kg b.w.) followed by oral administration of saline at 20 mL/kg. The highest dose produced a significant increase ($p<0.01$) in urinary volume over a period of 3 hours, comparable to that of hydrochlorothiazide at 25 mg/kg. Excretion of K^+, Na^+ and Cl^- increased significantly at 100 mg/kg b.w. compared to controls ($p<0.05$, $p<0.01$ and $p<0.01$ respectively), but less than with hydrochlorothiazide [Ohashi 2000b; Matsubara 1999].

Anti-inflammatory and analgesic effects
A lyophilised extract (16:1, methanol 50%) at oral doses of 500 and 1000 mg/kg b.w. significantly reduced hind paw oedema in rats at 3 and 5 hours after carrageenan administration ($p<0.01$ and $p<0.01$; $p<0.01$ and $p<0.05$, respectively). The extract at a dose of 1000 mg/kg b.w. produced significant ($p< 0.05$) analgesic activity in both the acetic acid-induced writhing test and the formalin-induced licking test (late phase) in mice and rats. The extract showed no effect on the tail flick test and hot plate test in mice [Yam 2008].

Oral administration of a flavonoid-rich chloroform extract fraction of the leaves at a dose of 1000 mg/kg b.w. significantly reduced carrageenan-induced rat paw oedema after 3 and 5 hours by 41 and 57% ($p<0.05$). This fraction, at oral doses of 500 and 1000 mg/kg b.w., significantly ($p<0.01$ and $p<0.001$) prevented dye leakage into the peritoneal cavity and inhibited the carrageenan-induced oedema; the higher dose showed an effect comparable to 10 mg/kg indomethacin [Yam 2010].

Orthosiphols A and B, applied topically at 200 µg/ear, inhibited the inflammation of mouse ears induced by 2 µg of 12-*O*-tetradecanoylphorbol-13-acetate by 42% and 50% respectively [Masuda 1992b].

Antipyretic effects
A lyophilised extract (16:1, methanol 50%) at oral doses of 500 and 1000 mg/kg b.w. showed no effect on normal body temperature but did significantly ($p<0.05$ and $p<0.01$) reduce its yeast-induced elevation, with the effect persisting up to 4 hours after administration and comparable to that of 150 mg/kg b.w. paracetamol p.o. [Yam 2009].

Hypoglycaemic and other metabolic effects
A dried aqueous extract (yield 3.3%) dissolved in saline was administered to rats by gavage at doses of 0.5 and 1.0 g/kg b.w.; the control group received saline at 5 mL/kg b.w. In rats treated with an oral glucose load or streptozotocin, the extract produced a hypoglycaemic effect (no values given). The effect of the extract on streptozotocin-induced diabetes was comparable to that of 10 mg/kg of glibenclamide [Mariam 1996].

An aqueous extract (25:1) at an oral dose of 0.2 to 1.0 g/kg b.w. significantly ($p<0.05$) decreased plasma glucose concentration comparable to glibenclamide (5 mg/kg b.w.) in streptozotocin-induced diabetic rats. After repeated daily administration of 0.5 g/kg b.w. for 14 days, it significantly ($p<0.05$) reduced plasma glucose on days 7 and 14. At the end of the study, plasma triglyceride concentration was significantly ($p<0.05$) lower in the treatment group compared to control. Plasma HDL cholesterol was significantly ($p<0.05$) increased in animals treated with the extract [Sriplang 2007].

Blood glucose, urea nitrogen and creatinine were slightly increased after oral administration of an aqueous extract (9:1) at doses of 5 and 10 mg/kg b.w. to Sprague-Dawley rats [Adam 2009].

A subfraction of a chloroform extract significantly ($p<0.05$) reduced blood glucose levels in the subcutaneous glucose tolerance test at a dose of 1 g/kg b.w. in rats loaded subcutaneously with 150 mg/kg b.w. glucose. In streptozotocin-induced diabetic rats this fraction did not exhibit a hypoglycaemic effect up to 7 hours after treatment [Mohamed 2011].

Effects on blood pressure and heart rate
Methylripariochromene A at doses of 50 and 100 mg/kg b.w. was administered subcutaneously to conscious, stroke-prone, spontaneously hypertensive male rats. A decrease of 15-30 mm Hg in mean systolic blood pressure was observed from 3.5 to 24 hours with the higher dose ($p<0.05$ and $p<0.01$ respectively), whereas no changes were observed in the control group. The lower dose caused a significant decrease ($p<0.05$) only at 8 hours. The substance also significantly ($p<0.01$) reduced the heart rate (75 and 45 beats/min at 6.0 and 8.5 hours, respectively, after administration of the higher dose), initial values in the treatment groups being 334 (at 50 mg/kg) and 340 (at 100 mg/kg) beats/min, and in the control group 345 beats/min. A slight decrease in heart rate was observed 6 hours after administration of the lower dose; the heart rate returned to baseline after 24 hours [Ohashi 2000b; Matsubara 1999].

Hepatoprotective effects
Pretreatment of rats with a lyophilised extract (16:1, methanol 50%) at oral doses of 125, 250, 500 and 1000 mg/kg dose-dependently reduced CCl_4-induced necrotic changes in rat liver. The increase of serum ALT and AST activity was inhibited significantly by doses of 250, 500 and 1000 mg/kg p.o. ($p<0.05$, $p<0.01$ and $p<0.01$ respectively) [Yam 2007].

Two groups of 8 male Sprague Dawley rats received a 95% ethanolic extract (yield 8.1 %) at a dose of 100 or 200 mg/kg b.w. orally for two months as well as a parenteral dose of thioacetamide three times weekly at a dose of 200 mg/kg b.w.. Treatment with the extract, as well as with silymarin (50 mg/kg b.w. orally), significantly ($p<0.05$) reduced the level of liver function biomarkers (ALT, AST, ALP, bilirubin) and malondialdehyde as antioxidant parameter. At a dose of 100 mg/kg b.w. the effect was only marginal, whereas at 200 mg/kg b.w. the extract prevented liver damage induced by thioacetamide as could be shown by 7 different parameters [Alshawsh 2011].

Gastroprotective effects
Oral administration of a 50% methanolic extract at doses between 125 and 1000 mg/kg administered together with absolute ethanol significantly decreased the ulcer index from 9.0 ± 0.5 in the control group to values between 6.7 ± 0.6 and 1.2 ± 0.3 ($p<0.01$ and 0.001 respectively); as compared to omeprazole (30 mg/kg b.w., ulcer index 1.8 ± 0.5). Histological studies of the rat stomach also showed a marked prevention of mucosal damage in groups which received the mentioned doses of the extract together with omeprazole [Yam 2009].

Antiproliferative and antiangiogenic effects
A 50% ethanolic extract demonstrated a 47.6 ± 6.4 % suppression ($p<0.05$) of HCT 116 tumour growth in athymic mice at an oral daily dose of 100 mg/kg b.w., and an 83.4 ± 4.1 % suppression ($p<0.01$) at a dose of 200 mg/kg b.w. for 4 weeks. In the enzyme-linked immunosorbent assay the extract at 200 mg/kg significantly ($p<0.05$) reduced the vascular endothelial growth factor level (91 ± 2 pg/mL tissue homogenate) compared to control (136 ± 4 pg/mL) [Ahamed 2011].

Pharmacological studies in humans

Diuretic activity
In a placebo-controlled, double-blind crossover study, no influence on 12- or 24-hour urine output or sodium excretion was observed in 40 healthy volunteers after administration of 600 mL (3 times 200 mL at 4-hour intervals) of a decoction equivalent to 10 g of dried leaf [Doan 1992].

Six healthy male volunteers drank 4 times 250 mL of a decoction of Java tea at 6-hourly intervals during one day, for comparison they drank the same amounts of water on a separate control day. The acidity of the urine increased 6 hours after ingestion of the tea. There were no changes in urine volume or electrolytes [Nirdnoy 1991].

From much earlier observations in healthy volunteers, however, increased diuresis was reported after oral administration of aqueous extracts of Java tea (400 mL/day of a 3.75% extract, 400 mL/day of a 15% extract, 500 mL/day of a 3.3% extract) [Schumann 1927; Gürber 1927; Westing 1928].

Clinical studies
An open study in 67 patients suffering from uratic diathesis did not reveal any influence of Java tea on diuresis, glomerular filtration, osmotic concentration, urinary pH, plasma content or excretion of calcium, inorganic phosphorus and uric acid during 3 months of treatment [Tiktinsky 1983].

Forty-eight patients with nephrolithiasis identified by ultrasonography were recruited and randomly assigned to two groups. For a period up to 18 months they received 5g of a related species *O. grandiflorus* daily (as an infusion) or 5-10 g of a sodium potassium citrate solution as a control. Every 5 to 7 weeks the patients were interviewed, given a kidney ultrasound, and urine samples were collected. From the recorded ultrasound images, rates of stone size reduction per year were calculated. The mean value was 28.6 ± 16.0% and 33.8 ± 23.6% for verum and control respectively, with no significant difference [Premgamone 2001.

In a placebo-controlled study, patients suffering from nephrolithiasis with multiple health complaints (at least two active symptoms), and negative for urine white blood cells, received an aqueous dry extract at a daily dose corresponding to 3.2 to 3.6 g dried leaves (n=36) or placebo (n=40) for 14 days. Neither group was permitted to consume any of 25 purine-rich foods during treatment. The primary measure was the reduced sum of active severity of symptoms as recorded using the visual analogue scale before and after therapy (i.e. on day 7 and 14). The mean of the total symptom scores (95% CI) was decreased significantly ($p<0.001$) in both groups; from 185.6 to 94.7 in the verum group and from 196.1 to 89.6 in the placebo group [Premgamone 2009].

Pharmacokinetic properties

Six adult male Sprague-Dawley rats were administered either a Java tea extract (containing 15 mg/kg sinensetin, 21 mg/kg eupatorin and 5 mg/kg 3′-hydroxy-5,6,7,4′-tetramethoxyflavone) orally or a mixture containing 2.5 mg/kg of each of these flavonoids intravenously, in a cross-over study with a wash out period of one week. The calculated mean absolute oral bioavailability for sinensetin was 9.4%, for eupatorin 1.0% and for 3′-hydroxy-5,6,7,4′-tetramethoxyflavone 1.5% [Loon 2005].

One hour after oral administration of an extract (not further specified) to rats, the maximum plasma concentration of betulinic acid was 1.2 ± 0.3 µg/mL [Akowuah 2008].

Preclinical safety data

In vitro experiments
In a somatic segregation assay using the diploid strain *Aspergillus nidulans* D-30, no genotoxic effects (mitotic crossover, chromosome malsegregation, clastogenic damage) were detected after plate incorporation of an ethanolic extract of Java tea (7.4% dry matter) at 1.4 mg/mL [Ramos Ruiz 1996].

In the Ames test, with and without metabolic activation, an aqueous extract (yield 4.8%) at a dose of up to 5000 µg/plate did not increase the number of revertant colonies. In the mouse bone marrow assay the extract did not alter the polychromatic: normochromatic erythrocytes ratio, nor did it increase the incidence of micronucleated polychromatic erythrocytes. No overt toxicity and no change in CYP1A and 2B9/10 activities were observed [Muhammad 2011].

In vivo experiments
The LD_{50} of a lyophilised extract (16:1, methanol 50 %) after oral administration to rats was higher than 5 g/kg b.w. [Yam 2008].

Acute toxicity
The acute toxicity of an extract (containing 0.15 % sinensetin, 0.21 % eupatorin and 0.05 % 3′-hydroxy-5,6,7,4′-tetramethoxyflavone) was studied in Sprague Dawley rats which had received a single oral dose of 5 g/kg b.w. and been observed for 14 days. The animals did not show any signs of toxicity. General behaviour, body weight, food and water intake, relative organ weight, haematology and clinical biochemistry were unaffected as compared to control. The LD_{50} was estimated to be more than 5 g/kg b.w. [Abdullah 2009].

A dry aqueous extract re-dissolved in saline was administered to rats by gavage at 0.5 and 1.0 g/kg b.w., while a control group received saline only (5 ml/kg). Treatment of 6 normoglycaemic rats with the extract at 0.5 mg/kg b.w. had no significant effect on fasting blood glucose levels during a 7-hour period. At 1.0 mg/kg, however, a significant decrease ($p<0.05$) in blood glucose concentration was observed in comparison with the control group [Mariam 1996].

A single dose of 5 g/kg of a 50% ethanol extract was given orally to 5 healthy Sprague-Dawley female adult rats. The rats were observed for clinical signs for 3 h and then periodically for 14 days. The extract caused neither visible signs of toxicity nor mortality until the end of observation period [Mohamed 2010].

Subchronic toxicity
Possible toxic effects following 14 days of oral administration of a methanolic extract (not further specified) were investigated in female Sprague Dawley rats. Control groups were given distilled water (vehicle) orally while the four test groups received 0.5 g/kg, 1 g/kg, 3 g/kg and 5 g/kg b.w. of the extract daily. Toxicity of the extract was evaluated by the incidence of lethality and blood serum biochemical parameters. Neither lethality nor toxic effects were seen in any group. A significant ($p< 0.05$) decrease in several serum biochemical parameters i.e. AST and ALT and increase in liver weight was observed in young female rats. No delayed toxic effects or lethality were observed in all animals during the following 14 days [Chin 2008].

In a study in female and male Sprague Dawley rats, a 50% ethanolic extract was administered orally at doses of 1.25, 2.5 and 5 mg/kg b.w. per day for 28 days. There were no signs of mortality and no significant differences in the general condition, growth or haematological parameters. The animals were sacrificed with subsequent examination of their organ weights, and gross as well as microscopic appearance of the

organs. There was no difference between treatment groups and a control group [Mohamed 2010].

Clinical safety data
In a study involving 48 patients suffering from nephrolithiasis, no adverse effects were reported in those who had consumed 5 g of Java tea daily for 18 months [Premgamone 2001].

In a study with nephrolithiasis patients receiving an aqueous dry extract at a daily dose corresponding to 3.2 – 3.6 g dried leaves (n=36) or placebo (n=40) for 14 days, adverse effects including musculo-skeletal and gastrointestinal complaints, as well as headache, occurred mainly during the first week in the verum group [Premgamone 2009].

One case of hepatitis after intake of a product containing powdered Green tea and Java tea was reported but a causal relationship between the hepatitis and the intake of Java tea could not be established [Garcia-Moran 2004].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books*, ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009,* but are not available online for copyright reasons.

After purchase of a single monograph*,* the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

Only for personal use. Is not allowed the dissemination of this file

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-kB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-b	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

PASSIFLORAE HERBA

2023

Passionflower herb

DEFINITION

Passionflower herb consists of the fragmented or cut, dried aerial parts of *Passiflora incarnata* L. of the swertisin chemotype or the isovitexin chemotype or a mixture of both. It may also contain flowers and/or fruits. It contains not less than 1.0 per cent of total flavonoids, expressed as isovitexin ($C_{21}H_{20}O_{10}$, M_r 432.4), calculated with reference to the dried drug [Passionflower herb].

The material complies with the European Pharmacopoeia [Passionflower herb].

Fresh material may also be used provided that when dried it complies with the European Pharmacopoeia.

CONSTITUENTS

Flavonoids, mainly glycosylflavonoids of apigenin and luteolin, e.g. isovitexin, isoorientin and their 2"-*O*-β-D-glucosides, schaftoside, isoschaftoside, vicenin-2 and swertisin, with considerable variation in qualitative and quantitative composition according to source [Glotzbach 1968, Schilcher 1968, Geiger 1986, Qimin 1991, Schmidt 1993, Rehwald 1994, Chimichi 1998, Rahman 1997, Raffaelli 1997, Voirin 2000, Grice 2001, Ferreres 2007, Wohlmuth 2010, Avula 2012]; traces of essential oil containing more than 150 components [Buchbauer 1992]; a cyanogenic glycoside, gynocardin [Spencer 1984]; amino acids with GABA as dominant component [Meier 1995, Elsas 2010].

Traces of β-carboline alkaloids (e.g. harmol, harmalol, harman) may be present, depending on the source, the maturity of the plant and the extraction method used [Löhdefink 1974, Lutomski 1981, Brasseur 1984, Rehwald 1995, Tsuchiya 1999a, 1999b, Grice 2001, Abourashed 2003, Frye 2007], but investigations using highly sensitive UPLC-UV-MS detected no β-carboline alkaloids in a number of validated samples of *Passiflora incarnata* [Avula 2012].

The structure of a tri-substituted derivative of α-naphthoflavone (7,8-benzoflavone), isolated from a methanolic leaf extract [Dhawan 2001a; 2004], has never been disclosed and attempts to re-isolate the compound were not successful [Holbik 2010].

CLINICAL PARTICULARS

Therapeutic indications
Tension, restlessness and irritability with difficulty in falling asleep [Bradley 1992, Akhondzadeh 2001a, Movafegh 2008, Meier 2013, Krenn 2016, Gibbert 2017, Lee 2020].

Posology and method of administration

Dosage

Adult single dose, three to four times daily: 0.5-2 g of the drug; 2.5 g of drug as infusion; 1-4 mL of tincture (1:8); other equivalent preparations [Bradley 1992, Schilcher 1995, Meier 2013, Krenn 2016].

Children from 3 to 12 years under medical supervision only: proportion of adult dose according to body weight.

Method of administration
For oral administration.

Duration of administration
No restriction; neither dependence nor withdrawal symptoms have been reported.

Contra-indications
None known.

E/S/C/O/P MONOGRAPHS

Only for personal use. Is not allowed the dissemination of this file

Special warnings and special precautions for use
None required.

Interaction with other medicinal products and other forms of interaction
None reported.

Pregnancy and lactation
No data available.

The use of passionflower herb dry extracts, fluid extracts and mother tinctures is assumed to be safe in the first and second trimester as well as during lactation, but should not take place without medical advice. The use in the third trimester is not recommended [Herba Pro Matre 2014].

Effects on ability to drive and use machines
None known.

Undesirable effects
Hypersensitivity possible in very rare cases [Smith 1993, Echechipia 1996].

One case of nausea, bradycardia and ventricular arrythmia was reported [Fisher 2000].

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Effects on receptor binding
Two dry extracts (3.0% and 9.1% total flavonoids respectively) were studied for their binding affinity to three receptors. At concentrations from 10 to 1000 µg/mL they did not interact with the binding sites of benzodiazepine, dopaminergic and histaminergic subtypes. Isovitexin-2"-*O*-glucoside and isoorientin-2"-O-glucoside did not inhibit the benzodiazepine binding site in concentrations up to 30 µM [Burkard 1997].

An ethanolic extract (not further specified) did not inhibit various CNS receptors expressed in Chinese hamster ovary cells, such as opioid (µ, κ, δ, OFQ), serotonin (5-$HT_{1Dβ}$, 5-HT_6, 5-HT_7), α-oestrogen, histamine (H-1, H-2), neurokinin-1 and metabotropic glutamate receptors. Only binding of ^{3}H-GABA to the $GABA_A$-receptor was potently inhibited at 1 µg/mL [Simmen 1999].

In CA1 pyramidal cells in hippocampal slices from male Sprague–Dawley albino rats, a dry extract (5.6:1; 44% ethanol) at concentrations from 128 to 512 µg/mL evoked a direct current with a dose-dependent amplitude. The current was obviously mediated by $GABA_A$-receptors as it was completely but reversibly blocked by the $GABA_A$-receptor antagonist GABAzine. After removal of amino acids from the extract, including GABA, no effect was observed at a dose of 138 µg/mL [Elsas 2010].

[^{3}H]-GABA uptake into rat cortical synaptosomes was inhibited by a dry extract (5-7:1, 50% ethanol) with an IC_{50} value of 97.5 µg/mL, but no effects on GABA release and GABA transaminase activity were seen. The binding of the specific $GABA_A$-receptor antagonist [^{3}H]-SR95531 to rat $GABA_A$-receptors and of the $GABA_B$ receptor antagonist [^{3}H]-CGP 54626 to $GABA_B$-receptors were inhibited by the extract in a concentration-dependent manner (IC_{50} 101 µg/mL and 120 µg/mL respectively). The ethanol- and benzodiazepine-sites of the $GABA_A$-receptor were not affected [Appel 2011].

Other effects
Fifteen strains of *Helicobacter pylori* were inhibited by a 95% methanolic extract (MIC 50 µg/mL) [Mahady 2005].

In a study on circadian rhythm in NIH3T3 clone 5611 cells, an extract (50% ethanol, yield 20.5%) at 100 µg/mL significantly reduced the mRNA expression of the core clock genes brain-muscle ARNT-like protein 1 (Bmal1) and cryptochrome 1 (Cry1) at 4 h, circadian locomotor output cycles kaput at 4 and 8 h and period circadian protein 1 (Per1) at 8 h ($p<0.05$ and $p<0.01$). From 12 hours onwards until 24 hours it increased the mRNA expression of Bmal1, Per1, Per2 and Cry1 as well as of SOD1 and GPx. Isovitexin-2"-*O*-glucoside and homoorientin at 10 µg/mL and isoschaftoside and homoorientin at 30 µg/mL significantly ($p<0.05$ and $p<0.01$) enhanced the circadian expression of Per2 [Toda 2017].

In rat C6 glioma cells, an extract (60% ethanol; leaves and fruits 8:2) at 0.6 and 6 µg/mL significantly ($p<0.05$ and $p<0.005$ respectively) increased the ROS production as compared to vehicle [Kim 2020].

A methanolic extract significantly ($p<0.05$) increased the expression of the brain derived neurotrophic factor (BDNF) in human neuroblastoma SH-SY5Y cells by 74.1% at 30 µg/mL and by 56.6% at 10 µg/mL. In a metabolomic approach, primary metabolites belonging to the Krebs cycle were shown to be positively correlated with BDNF activity [Gonulalan 2020].

The organic anion transporting polypeptides 2B1 and 1A2 (OATP2B1 and OATP1A2) are involved in the transport of endogenous sulphated steroid hormones, which are assumed to play a role in neurosteroid homeostasis. The effect of apigenin, orientin and vitexin, as well as of two preparations (425 mg dry extract, 5-7:1, 50% ethanol or 300 mg powdered drug respectively), on the OATP2B1- and OATP1A2-mediated transport of dehydroepiandrosterone sulphate (DHEAS), estrone-3-sulphate (ES) and pregnenolone sulphate (PS) were tested. Apigenin decreased the accumulation of all three sulphates in OATP2B1 and OATP1A2 overexpressing cells. Orientin reduced the cellular amount of DHEAS and PS in OATP2B1 expressing cells and showed no influence in OATP1A2 expressing cells. For vitexin, a reduction of ES and PS in OATP2B1 and of PS in OATP1A2 expressing cells was observed. Orientin was identified as inhibitor and substrate for both transporters, vitexin only for OATP2B1 and apigenin only for OATP1A2. At a concentration of 50 µg/mL, the dry extract significantly ($p<0.05$) reduced the transport of all steroids with both transporters, whereas the effect of the powdered drug was distinctly less [Schäfer 2022].

In vivo experiments

Sedative and anxiolytic effects
After oral administration of a dry extract (2.6% flavonoids) at a dose of 800 mg/kg b.w. to mice, a significant ($p<0.01$) anxiolytic effect was observed with a prolongation of the hexobarbital-induced sleeping time whereas the locomotor activity remained unaffected [Della Loggia 1981].

After i.p. administration in rats, a hydroethanolic dry extract (not further specified) at a dose of 160 mg/kg b.w. significantly ($p<0.01$) prolonged sleeping time induced by pentobarbital, and at 50-400 mg/kg, reduced spontaneous locomotor activity in a dose-dependent manner. Administered orally or i.p. at a dose of 160 mg/kg, the extract significantly ($p<0.05$ to $p<0.01$) raised

Only for personal use. Is not allowed the dissemination of this file

the threshold to nociceptive stimuli in the tail flick and hot plate tests [Speroni 1988].

Rats showed reduced activity in a one-arm radial maze after one week of daily oral administration with an alcohol-free hydroethanolic extract (10 mL/kg b.w., corresponding to 5 g/kg of the drug) [Sopranzi 1990].

The activity of a liquid hydroethanolic extract from cryoground fresh plant after removal of ethanol was determined in mice. Oral treatment of mice with doses of 25 and 50 mL/kg b.w. (corresponding to 1.25 and 2.5 g/kg of dried drug respectively [Chefaro-Ardeval]) reduced exploratory and spontaneous motor activities, prolonged sleeping time induced by pentobarbital and inhibited aggressiveness and restlessness caused by amphetamine tartrate. The sedation index was comparable with that of meprobamate (250 mg/kg b.w.) and higher than that of diazepam (10 mg/kg b.w.) and chlordiazepoxide (10 mg/kg b.w.) [Galliano 1994].

No sedative effects were observed in two different experimental models in mice (hexobarbital-induced sleeping time, exploratory activity) after oral administration of a dried 30% hydroethanolic extract (1.75 and 3.5 mL/kg b.w.) [Weischer 1994].

The sedative effect of a dry extract (4.5:1, ethanol 70%), was investigated in male Swiss mice. The extract (100 mg/kg b.w.) was administered i.p. 10 min before s.c. injection of sodium pentobarbital (40 mg/kg). A distinct prolongation of mean sleeping time by 40% was observed compared to control. When administered by gastric tube 1 h before s.c. injection of amphetamine sulphate (5 mg/kg b.w.), the extract (50 mg/kg) caused a significant reduction ($p<0.05$) in hypermotility in an activity cage. In comparison with the control group an average reduction in motility of 17% was observed 120 minutes after administration of amphetamine sulphate [Capasso 1995].

An aqueous extract (79:1) administered i.p. to male Swiss mice showed sedative activity at doses of 25, 50 and 100 mg/kg b.w.. A dose-dependent reduction of the locomotor activity in an activity cage and a significant ($p<0.05$ to $p<0.01$) decrease of motor coordination at 20, 40, 80 and 120 minutes after treatment were observed in a rotarod apparatus. The pentobarbital-induced sleeping time was prolonged dose-dependently, significantly ($p<0.01$) at doses of 50 and 100 mg/kg b.w. [Capasso 1996].

Swiss mice received a hydroethanolic dry extract (2% flavonoids) at i.p. doses of 60, 125 and 250 mg/kg b.w.. A dose-dependent reduction of the spontaneous locomotor activity was recorded, significant ($p<0.05$ and $p<0.01$ respectively) at the two higher doses. Intragastric administration at the same doses resulted in a less distinct decrease of activity. Oral treatment with 30, 60 and 125 mg/kg b.w. of a more hydrophilic extract (7.4% flavonoids) induced a dose-dependent reduction of the locomotor activity, significant ($p<0.01$) at doses of 60 and 125 mg/kg. The sodium pentobarbital-induced sleeping time was increased significantly ($p<0.01$) at these doses. Additionally, a significant ($p<0.01$) delay in the onset of convulsive episodes after administration of 50 mg/kg pentetrazol i.p. and an increase in the number of survivals were observed after pre-treatment of the animals with 60 and 125 mg/kg of the extract [Speroni 1996].

The sedative and anxiolytic properties of two lyophilized extracts (30% ethanol, 7.2:1; and aqueous, 7.6:1) from cryoground fresh aerial parts were assessed after i.p. administration to male Swiss albino mice. The aqueous extract reduced the activity in the staircase and free exploratory tests and prolonged the pentobarbital-induced sleeping time at doses of 400 and 800 mg/kg b.w. (expressed in terms of dry plant material). Pre-treatment with the benzodiazepine receptor antagonist flumazenil (10 mg/kg b.w.) did not influence the activity in the staircase test. The hydroethanolic extract significantly ($p<0.05$) enhanced the activity in the staircase and the light/dark avoidance tests at 400 mg/kg b.w. [Soulimani 1997].

The anxiolytic effect of various extracts was tested in the elevated plus-maze model in mice. After oral administration of 75 to 300 mg/kg b.w. neither the petroleum ether nor the chloroform and water extracts modified the behavioural parameters. The methanolic extract showed a significant ($p<0.001$) effect at doses of 75, 100, 125 and 200 mg/kg. At doses of 125 and 200 mg/kg, the effect was comparable to that of 2 mg/kg b.w. diazepam [Dhawan 2001b].

These findings were confirmed in another study using the same test, in which extracts of the different plant parts were compared. The methanolic extracts of all plant parts were the most effective ($p<0.05$ to $p<0.001$) [Dhawan 2001c].

Five dried tinctures (not further specified; 100, 200, 300 and 400 mg/kg b.w.) and a methanolic extract (125 mg/kg b.w.) were administered orally to Swiss Albino mice before testing in the elevated plus-maze. Four tinctures and the extract showed significant ($p<0.05$) anxiolytic effects as measured by the mean time spent in the open arms. Two of the tinctures were most active at a dose of 400 mg/kg, one at 300 mg/kg and one at 200 mg/kg, the fifth one was almost without effect [Dhawan 2002a].

No significant effects on sleep latency in sleep disturbed Wistar rats and on delta power during non-REM sleep were noted 6 hours after oral administration of an aqueous extract at a dose of 300 mg/kg or at the very high doses of 1000 and 3000 mg/kg b.w. [Shinomiya 2005].

An extract (70% ethanol, standardized to 4% flavonoids) administered orally to male Swiss mice at a dose of 250 mg/kg b.w. two hours before s.c. injection of 5 mg/kg amphetamine significantly reduced the amphetamine-induced hypermotility at 30, 60, 90 and 120 minutes ($p<0.05$ to $p<0.01$) as compared to vehicle control. The barbiturate-induced sleeping time was significantly ($p<0.05$) prolonged [Capasso 2005].

Male BL6/C57J mice were treated orally with 150, 375 or 600 mg/kg b.w. of an extract (not further specified) one hour before testing in the elevated plus maze model. Diazepam (1.5 mg/kg p.o.) served as a positive control. At 375 mg/kg the extract led to a significant ($p<0.01$) increase in the time spent in the open arms and in the number of open arm entries as compared to control. The effects were comparable to the positive control. Doses of 150 and 600 mg/kg had no effect [Grundmann 2009].

In a comparable study with an extract (5-7:1, 50% ethanol) at the dose of 375 mg/kg b.w., significant increments in the time spent in the open arms ($p<0.001$) and in the number of open arm entries ($p<0.05$) were observed as compared to control. The effects were abolished by pre-treatment with the $GABA_A$/benzodiazepine receptor antagonist flumazenil (3 mg/kg, i.p., 15 min before oral treatment with the extract), but not with the 5-HT_{1A}-receptor antagonist WAY-100635 (0.5 mg/kg, i.p., 15 min before oral treatment with the extract). Doses of 150 and 600 mg/kg of the extract did not show an effect [Grundmann 2008].

Five extracts (containing 2.8-46.4% total flavonoids) were prepared from fresh or dried material using 65% ethanol or water at different temperatures and extraction times. The extracts were given to CF-1 mice at 1 g/kg b.w./day for 1 week with the drinking water. Compared to control, one of the aqueous and one of the ethanolic extracts reduced pentetrazol-induced stage 4 seizures. No influence was seen on the sensomotor activity in the rotarod model for any of the extracts. In contrast to several

Only for personal use. Is not allowed the dissemination of this file

other studies, all extracts increased the anxiety level as shown by the time spent in the open arms, the extending over edges of the open arms, the ratio of open arm entries and the distance moved in the open arms in the elevated plus maze model [Elsas 2010].

BALB/c mice were treated with a methanolic extract (200, 400 or 600 mg/kg b.w. p.o.) or diazepam (2 mg/kg i.p. in the staircase test or 4 mg/kg i.p. in the locomotor activity assay). In the staircase assay the extract at 200 mg/kg and diazepam significantly ($p<0.05$ and $p<0.001$ respectively) increased the number of steps climbed. At 400 mg/kg no change was observed as compared to control, at 600 mg/kg the number of steps was significantly ($p<0.05$) reduced. The number of rears significantly decreased after all treatments ($p<0.05$ to $p<0.01$). The latter effect was reversed by pre-treatment with pentetrazol (PTZ; 10 mg/kg i.p.). A significant reduction in locomotor activity was seen with the two higher extract doses ($p<0.01$ and $p<0.001$) as well as with diazepam ($p<0.001$). PTZ only reverted the effects of the extract but not of diazepam [Aman 2016].

Male Wistar albino rats received an extract (60% ethanol; 5-7:1; 4.43% flavonoids) at dosages of 30, 100 or 300 mg/kg b.w./day with their drinking water for 7 weeks before and 2 weeks during testing. In the water maze test, the extract at 100 and 300 mg/kg significantly (all $p<0.05$ compared to control) decreased the mean latency and the mean path to the platform; the mean percentage of time the animals searched actively for the platform was significantly increased. The mean velocity of swimming was significantly ($p<0.0001$) higher after 30 and 300 mg/kg. In the memory test, a significant increase in the number of crossings over the previous platform position ($p<0.05$) and a significantly lowered stress level ($p<0.0001$) were observed after all doses. The experimental groups showed changes in the concentrations of 5-HT in the prefrontal cortex, hippocampus, hypothalamus and striatum and in the 5-HT turnover in the prefrontal cortex, hippocampus and striatum as well as of the noradrenaline metabolite 3-methoxy-4-hydroxyphenylglycol in the hypothalamus. A significant ($p<0.05$) difference was found between experimental groups for the concentration of glutamic acid in the hippocampus [Jawna-Zboińska 2016].

An extract (50% ethanol, yield 20.5%) was administered orally to male ICR mice at a dose of 100 mg/kg/day for 15 days. Significant reduction of sleep latency and an increase in sleeping time were observed in the pentobarbital-induced sleep test (both $p<0.05$ as compared to control). In the serum, the extract induced high-amplitude rhythms in the corticosterone levels and enhanced the circadian expression of Bmal1, circadian locomotor output cycles kaput and Per1. In the liver, high-amplitude rhythms in Per1, Per2, and Cry1 gene expression were observed. In the cerebrum, dopamine levels and the mRNA expression of the monoamine oxidases A and B, of catechol-*O*-methyltransferase and of glutamic acid decarboxylase were enhanced [Toda 2017].

In 6 Wistar rats, the EEG, the ocular activity and the electromyogram were measured for 9 hours the day before treatment and for 9 hours after i.p. administration of 500 mg/kg b.w. of an extract (60% ethanol; removal of the ethanol and replacement to the original volume by water). A significant ($p<0.05$) decrease in the time of wakefulness and an increase ($p<0.05$) in the time of slow wave sleep (SWS) were observed. The latency of SWS dropped from 44.4 min to 25.9 min. The effects on REM sleep were inconsistent and not significant. A trend towards a reduction of the number of REM sleep phases was observed [Ayala Guerrero 2017].

ICR mice treated orally with an extract (60% ethanol, leaves and fruits 8:2) were administered either single doses of 250 and 500 mg/kg b.w. or 250 mg/kg b.w. daily for 5 days. Immunohistochemical staining showed the primary reaction area in the brain around the mammillary body. Compared to vehicle, the serum melatonin levels were significantly elevated after the single dose of 500 mg/kg ($p<0.01$) and after the repeated doses ($p<0.05$). The immobility time increased with the single dose of 500 mg/kg ($p<0.0001$) and with the repeated doses on days 1 to 5, reaching significance ($p<0.05$) only on day 5. In SD rats, an increase in the eye closing time was observed after a single oral dose of 500 mg/kg ($p<0.0001$) and after repeated oral doses of 250 mg/kg on days 3 ($p<0.05$) and 5 ($p<0.005$) [Kim 2020].

In C57BL/6 mice, receiving the same extract orally at 500 mg/kg b.w. daily for 5 days, significant decreases in energy expenditure and activity during the dark cycle ($p<0.0005$ and $p<0.005$ respectively) as well as over 24 hours ($p<0.005$ and $p<0.05$ respectively) were observed. The serum level of melatonin and the expression of calretinin in the hypothalamus and the hippocampus were increased significantly (all $p<0.0005$). The serum serotonin level was not changed [Kim 2019a].

Addition of the same extract at 2 mg/mL to the drinking water of Sprague Dawley rats for 12 days resulted in significant increases in the melatonin and serotonin concentrations in the serum ($p=0.0339$ and $p=0.0396$ respectively) as compared to control. No significant differences in body weight gain, food intake and water consumption were seen [Kim 2019b].

Weaned piglets (n=120) received either a control diet or this diet supplemented with an extract (70% ethanol) equivalent to 1 g passionflower herb /kg fodder, standardized to 3.5% total flavonoids, for 28 days. No differences between the groups were seen in growth performance. The presence of skin lesions and the IgA and cortisol concentrations in saliva were assessed on days 1, 10, 19 and 28. In the extract group fewer ear lesions ($p<0.05$), less aggressive behaviour ($p<0.001$), higher enrichment exploration ($p<0.001$) and lower cortisol levels ($p<0.01$) were observed. The effect on tail lesions ($p<0.001$) and behavioural observations ($p<0.001$) were time-dependent [Pastorelli 2022].

Three fractions from an extract (5-7:1, 50% ethanol, fractionated with petroleum ether, chloroform and butanol) were tested in mice in the elevated plus-maze model. The animals received oral doses of the fractions equivalent to 150, 300 and 750 mg/kg b.w. of the extract. At the two lower doses, the butanol fraction significantly ($p<0.05$) increased the number of open arm entries and the time spent in open arms. The highest activity for both parameters was observed with the chloroform fraction at the lowest dose ($p<0.001$). The petroleum ether fraction remained without effect [Sampath 2011].

Effects on withdrawal symptoms

Male Wistar rats were sensitized with 0.4 mg/kg b.w. nicotine for 4 days. On day 5 their spontaneous locomotor activity was determined in an activity chamber. After 25 min habituation time, the animals received an extract (water-glycerol 1:1; 800 mg/kg b.w. i.p.) or vehicle and after another 25 min. a challenge dose of nicotine. From 20 to 40 minutes after challenge a significant ($p<0.05$ to $p<0.01$) decrease in average velocity was observed in the passionflower herb group as compared to vehicle [Breivogel 2012].

Four groups of male Wistar rats received by oral gavage either i) water for 19 days, and after one day of no treatment water for another 8 days, or ii) water for 19 days, and after one day of no treatment an extract (standardized to 7% of flavonoids, 200 mg/kg b.w. for 8 days, or iii) ethanol for 19 days (4 g/kg b.w.), and after one day of no treatment water for another 8 days, or iv) ethanol for 19 days, and after one day of no treatment the extract for 8 days. In the ethanol-treated groups the nociceptive threshold in the hot plate test increased after ethanol withdrawal. The increase was reversed by the extract ($p<0.05$). No improvement of the increased nociceptive threshold was observed in the tail

Only for personal use. Is not allowed the dissemination of this file

flick test. The extract did not influence the levels of BDNF and interleukin-10 in the prefrontal cortex, the brainstem and the hippocampus [Schunck 2017].

Antitussive effects
A methanolic extract from dried leaves (yield 4.1%) was administered orally to Swiss mice at doses of 100 and 200 mg/kg b.w. before exposure to SO_2 and coughing was recorded for 5 minutes after challenge. The extract led to an inhibition of 39.4% and 65.0% respectively ($p<0.01$ compared to vehicle control). With codeine as positive control, inhibitions of 34% at 10 mg/kg and 61% at 20 mg/kg were observed [Dhawan 2002b].

The same extract was tested in an asthma model in guinea pigs measuring bronchospasms induced by acetylcholine chloride aerosol. The time until the appearance of bronchospasms (preconvulsive time PCT) was measured. Then the animals received the extract (50, 100 or 200 mg/kg b.w. p.o) for seven days. Two hours after the last dose the acetylcholine chloride challenge was repeated. At 100 and 200 mg/kg the extract showed a significant ($p<0.05$) increase in the PCT with a protection of 53.3% and 28.9% respectively, as compared to control [Dhawan 2003a].

Anticonvulsive effects
Male Balb/c mice received a hydroalcoholic extract (4% flavonoids; 0.05, 0.1, 0.2 or 0.4 mg/kg b.w. i.p.) 30 min before i.p. injection of PTZ. At 0.2 and 0.4 mg/kg, the extract significantly ($p<0.001$) prolonged the onset time of seizures as compared to vehicle. The highest dose also decreased the duration of seizures ($p<0.001$). Pre-treatment with flumazenil or naloxone 5 min before the administration of the extract reversed the effects [Nassiri-Asl 2007].

The same extract was injected intracerebroventricularly in male Wistar rats 30 min before i.p. injection of PTZ. At a dose of 1.5 µg/kg b.w., the latency to first minimal clonic seizures was significantly ($p<0.01$) prolonged and at 0.55 and 1.5 µg/kg also the latency to the first generalized clonic seizures ($p<0.01$) as compared to vehicle control. The survival rate increased dose-dependently. Intracerebroventricular pre-treatment with flumazenil abolished the effects of the extract [Nassiri-Asl 2008].

Male Swiss albino mice were injected with PTZ (50 mg/kg b.w. i.p.) on days 1, 5, 10 and 15. From days 5 to 15 the animals received daily either a hydroethanolic extract (not further specified) at 150, 300 or 600 mg/kg b.w. i.p., diazepam (2 mg/kg i.p.) or vehicle. The extract significantly ($p<0.05$) decreased the seizure severity score at 300 and 600 mg/kg on day 5, and at all doses on days 10 and 15 as compared to vehicle control. At 300 and 600 mg/kg no seizures were observed on day 15 and on days 10 and 15 respectively. The extract at the highest dose significantly ($p<0.05$) reduced the immobility time in the forced swimming test on day 15 as compared to vehicle control. Brain noradrenaline and serotonin levels were significantly ($p<0.05$) decreased by PTZ as compared to naïve control. The extract groups showed significant ($p<0.05$) increases in the noradrenaline level at 300 and 600 mg/kg, and in the serotonin level at all doses compared to vehicle control [Singh 2012].

In an epilepsy model, chemical kindling was induced in Swiss albino mice by sequential i.p. injections of subconvulsive doses of PTZ (35 mg/kg b.w. every 48 hours) for up to 45 days, and saline was administered for the naïve control. Following established kindling, mice received single oral doses of either vehicle or an extract (70% ethanol; yield 15%; 1.57 µg/g harmine, 0.32 µg/g harmaline, 10.45 µg/g harmalol) at doses of 150, 300 or 600 mg/kg. On days 5, 10 and 15 after the treatment the animals received a PTZ-challenge. After this challenge, significant ($p<0.05$) reductions were observed in the seizure severity scale, in the transfer latency in the elevated plus maze model and in the number of mistakes in the passive shock avoidance model in all verum groups at all time points as compared to kindled vehicle control. In the latter model, an increase in the step-down latency ($p<0.05$ for 300 and 600 mg/kg at all time points and for 150 mg/kg after 10 and 15 days) was shown compared to kindled vehicle control. The immobility period in the tail suspension test was reduced by all doses on days 5, 10 and 15, and significantly ($p<0.05$) so in the forced swimming test as compared to kindled and naïve vehicle controls. In the cortex and the hippocampus, compared to kindled control, all doses of the extract significantly ($p<0.001$) decreased the PTZ-induced elevated AChE levels. The two higher doses increased the PTZ-lowered dopamine and serotonin levels ($p<0.05$ to 0.001) and all extract doses the noradrenaline levels ($p<0.001$); the latter also compared to naïve control. PTZ-elevated nitrite levels decreased in the cortex ($p<0.001$ for all doses) and for 150 and 300 mg/kg in the hippocampus [Goel 2015].

Neuroprotective effects
In a Parkinson's disease model, neurodegeneration was induced in male Swiss albino mice with 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP; 20 mg/kg b.w. i.p. daily) for 4 days. Mice were subsequently treated orally with a methanolic leaf extract (200 and 400 mg/kg b.w.) for 14 days. Behavioural abnormalities were assessed in several models such as the Rotarod test, the Pole test, the catalepsy test, the beam walk test, Gait analysis and the adhesive removal test. In all models treatment with the extract significantly ($p<0.01$) and dose-dependently improved the behavioural deficits induced by MPTP. Both doses of the extract also significantly ($p<0.01$) ameliorated the reduced levels of dopamine, SOD, glutathione peroxidase and reduced glutathione and the increased concentrations of MAO B and glutamate in the corpus striatum of MPTP control mice [Narayanan 2011].

In a mouse model for insomnia, DBA/2 mice received an extract (60% ethanol, leaves and fruits 8:2) at oral doses of 10 or 50 mg/kg b.w. for 3 days. An improvement of neurogenesis was demonstrated by a significant ($p<0.001$) increase in the number of doublecortin- and Ki67-positive cells in the hippocampal gyrus. Administration of 100 mg/kg/day to these animals resulted in improved memory in the water maze model. In Sprague Dawley rats receiving the extract at 2 mg/mL with the drinking water for 12 days, doublecortin, parvalbumin, the BDNF and the melatonin receptor 1 were significantly increased ($p<0.02$ to $p<0.0012$). In both rodent models the expression of Tau was significantly higher ($p<0.007$ and $p<0.0011$), while the phosphoTau expression and the phosphoTau/Tau ratio were significantly lower (all $p<0.0001$) as compared to control [Kim 2019b].

Other effects
In carrageenan-induced paw oedema, dextran pleurisy and cotton pellet granuloma tests in rats, a dry extract (mixture obtained from a two-step hydroethanolic and aqueous extraction) exerted a dose-dependent anti-inflammatory effect after oral administration. Significant inhibition of carrageenan oedema at doses of 125 (19.5%, $p<0.05$), 250 and 500 mg/kg b.w. (48.1% and 55.7%, $p<0.01$) and of cotton pellet granuloma at doses of 250 (15.7%, $p<0.05$) and 500 mg/kg b.w. (20.2%, $p<0.01$) were observed [Borelli 1996].

A methanolic extract from dried leaves (yield 4.1%) was administered orally to Swiss male mice at single doses of 75, 100 and 150 mg/kg b.w. The mounting behaviour was tested three times for 15 min during three hours after administration. Compared to control, during all observation periods significant increases in the number of mounts on non-oestrous females were observed ($p<0.01$ 15 min after administration and $p<0.001$ 1.5 and 2.5 hours after administration). The dose of 100 mg/kg was most effective [Dhawan 2003b].

Only for personal use. Is not allowed the dissemination of this file

A methanolic leaf extract (yield 22.9%) was administered orally at daily doses of 100 and 200 mg/kg b.w. to streptozotocin (STZ)-induced diabetic Swiss albino mice for 14 days. At the end of the treatment the reduced body weight observed in diabetic controls was significantly ($p<0.05$) improved by the extract at 200 mg/kg, returning towards the normal level. At this dose of extract, on days 4, 7, 10 and 15 the elevated fasting blood glucose level in diabetic mice also decreased significantly ($p<0.01$ to $p<0.001$) and the diabetes-induced urine glucose level was reduced on days 7, 10 and 15, whereas the reduced liver glycogen level was significantly ($p<0.001$) increased. Significant ($p<0.01$ to $p<0.001$) improvements of the STZ-induced changes in the serum lipid profile (total glycerides, TC, VLDL-c, LDL-c, HDL as well as STC/HDL-c and LDL-c/HDL-c ratios) were observed. The extract at 200 mg/kg enhanced the regeneration of islets of Langerhans in the pancreas and the restoration to normal cellular size of islets with hyperplasia.

In an oral glucose tolerance test in normal fasting mice treated in the same way, the extract at 200 mg/kg significantly ($p<0.001$) reduced the serum glucose concentration at 0, 30, 60 and 120 min as compared to control. The effect was comparable to glibenclamide at 10 mg/kg p.o. [Gupta 2012].

Antinociceptive effects were shown for a methanolic extract (not further specified) in the abdominal restriction assay and the hot plate test in BALB/c mice. The animals received the extract at single doses of 150, 200 or 250 mg/kg b.w. p.o. or morphine (5 mg/kg i.p) or diclofenac (50 mg/kg i.p.). A significant attenuation of acetic acid-induced abdominal constriction was observed after the two higher doses of the extract ($p<0.01$ and $p<0.001$ as compared to saline control) as well as after diclofenac and morphine (both $p<0.001$). Naloxone (0.5 mg/kg s.c.) reversed the antinociceptive activity of the extract and of morphine but not of diclofenac.

The same extract was administered orally at 200 or 300 mg/kg to streptozotocin-induced diabetic Sprague Dawley rats in models of allodynia and vulvodynia. Gabapentin (75 mg/kg i.p.) served as positive control. In allodynia, 1 hour after administration a significant ($p<0.001$) increase in the paw withdrawal threshold was observed for both extract doses as well as for gabapentin, and in the paw withdrawal latency with the higher extract dose and with gabapentin. The extract did not show an effect in static vulvodynia. A significant ($p<0.001$) relief in dynamic vulvodynia was seen for both extract doses and gabapentin [Aman 2016].

In worm models (*Caenorhabditis elegans*), an extract (60% ethanol, leaves and fruits 8:2) at dilutions of 50 mg/L, 100 mg/L and 500 mg/L increased the survival rate under oxidative stress, significant at the highest dose ($p=0.0485$), and the mean and maximum lifespan of the worms were extended significantly ($p<0.025$ to $p<0.001$). The expression of the heat shock protein hsp-16.2, which is positively correlated with lifespan, was up-regulated in the long-lived worms treated with 250 mg/L of the extract ($p<0.0001$) [Kim 2019b].

Several studies using an unknown benzoflavone moiety from a methanolic leaf extract showed a reversal of tolerance and dependence of several addiction-prone psychotropic drugs in mice [Dhawan 2002c; 2002d; 2002e; 2002f; 2003c] as well as of declined sexuality in rats induced by the psychotropic drugs [Dhawan 2002g; 2003d; 2003e]. In male rats, the compound increased libido, sperm count and fertilization potential, which resulted in greater litter size after mating [Dhawan 2002h]. Nevertheless, the structure of this compound was never elucidated and re-isolation was not successful [Holbik 2010].

Pharmacological studies in humans

In a randomized, placebo-controlled, double-blind study performed in a cross-over design 12 healthy, female volunteers received either 1.2 g of an extract (5.9:1, solvent not specified), 10 mg of diazepam or placebo and 140 minutes later 100 mg of caffeine. The current state of alertness was rated by the subjects on a visual analogue scale (VAS) from "wide awake" to "almost asleep". VAS results 120 min after treatment with the extract reached about one third of the diazepam value compared to placebo. Quantitative EEG, for 5 minutes under vigilance-controlled reaction time conditions followed by 5 min under resting conditions, was measured before administration and 120 and 180 min after intake. The effects after administration of the extract were difficult to distinguish from placebo [Schulz 1998].

Healthy volunteers (27 female, 14 male; aged 18 to 35 years) consumed one cup of a tea (2 g passionflower herb/250 mL boiling water or 2 g parsley as placebo) 1 hour before bedtime for 7 days in a double-blind, placebo-controlled, repeated-measures design trial. After a one week wash-out period they changed to the other tea. On each treatment day, the participants completed a sleep diary preceding sleep and upon rising. On day 7 of each treatment the State-trait anxiety inventory (STAI) was completed. Ten participants also underwent overnight polysomnography on the last night of each treatment period. Of six parameters in the sleep diary, only subjective sleep quality showed a significantly ($p<0.002$) improved result for passionflower herb compared with placebo. In all other subjective and objective parameters, no differences between verum and placebo were observed [Ngan 2011].

In a randomized, double-blind, placebo-controlled study, stress was induced in healthy volunteers (30 female, 30 male; aged 24 to 31 years) by a simulated public speaking test. The participants received a dry extract (500 mg, standardized to 0.29% vitexin) or placebo 1.5 hours before the start of the stressful situation. During the stressful phase, the heart rate significantly ($p<0.05$) increased in the experimental group as compared to placebo, but significantly ($p<0.05$) declined throughout the speech compared to the placebo group. No differences between the groups were observed in the standardized anxiety measure STAI [Avelino da Silva 2017].

Healthy volunteers (n=44; ca. 22 of each gender) took 200 mg/day of a dry extract (50% ethanol; yield 20.5%; 3% flavonoid glycosides) one hour before going to sleep for 12 weeks in a randomized, placebo-controlled, double-blind trial. The Japanese version of the Medical Outcomes Study Short Form 36-Item Health Survey (SF-36) and the Oguri-Shirakawa-Azumi sleep score were used to assess emotional status and sleep quality at weeks 6 and 12. After 6 weeks significant improvements were seen in the SF-36 parameters role/social component summary ($p<0.01$), social functioning, role emotional and mental health (all $p<0.05$) as compared to placebo. After 12 weeks the mental component summary and vitality were significantly ($p<0.05$) better in the verum group. No significant differences between the groups were observed for any sleep parameters, blood pressure, pulse rate, haematological and biochemical components as well as urinary parameters at both time points of assessment [Takara 2019].

In a randomized, double-blind, placebo-controlled study, the influence of a single dose of a dry extract (50% ethanol, 850 mg corresponding to 4.25–5.95 g of passionflower herb) on EEG parameters in healthy volunteers (23 female, 17 male) was investigated. Quantitative EEG and eye tracking were recorded before and 45 min after intake of verum or placebo during observation of a video showing various audio-visual cognitive and emotional challenges in series. Before the intake, four cognitive and four emotional challenges induced increases in the beta-, delta- and theta spectral power mainly in fronto-temporal brain areas. These increases were attenuated 45 min after intake in the verum group as compared to placebo. The effects were

Only for personal use. Is not allowed the dissemination of this file

attributed to an influence on glutamatergic and GABAergic neurotransmission [Dimpfel 2016].

Clinical studies

Systematic reviews evaluating 9 and 6 studies respectively concluded that there is a potential for passionflower herb to alleviate some symptoms of neuropsychiatric origin [Miroddi 2013, Janda 2020].

In a randomized, double-blind, controlled study involving 36 patients (20 female, 16 male) with generalised anxiety disorder according to the Diagnostic and Statistical Manual of Mental Disorders (DSM IV) and a score of 14 or more on the Hamilton anxiety rating scale (HAM-A), 18 were treated for 4 weeks with 45 drops/day of a hydroethanolic extract (not further specified) and a placebo tablet. The control group (n=18) received 45 drops/day of a placebo and 30 mg of oxazepam per day. The HAM-A score was assessed on days 0, 4, 7, 14, 21 and 28. There were no differences between the groups in HAM-A score on days 0, 21 and 28. At day 4 the score in the passiflora group was significantly higher ($p<0.008$) than in the oxazepam group. At day 7 and 14 the difference was not significant. At all time points the effect of both treatments was significant ($p<0.001$) when compared to baseline [Akhondzadeh 2001a].

A total of 65 male opiate addicts going through withdrawal were treated in a randomized, double-blind, controlled study with 60 drops of a hydroethanolic extract (not further specified) and 0.8 mg clonidine or placebo drops and clonidine. The severity of the withdrawal syndrome was measured on days 0, 1, 2, 3, 4, 7 and 14 using the "Short Opiate Withdrawal Score". Both protocols were equally effective with regard to the physical symptoms of withdrawal; the passiflora/clonidine treatment was superior to clonidine alone for the psychological symptoms [Akhondzadeh 2001b].

In a randomized, double-blind, parallel-group trial, children (aged 6 to 13 years) with attention deficit hyperactivity disorder (ADHD) received 0.04 mg/kg/day of a preparation (not further specified) (n=17) or 1 mg/kg/day methylphenidate (n=17) for 8 weeks. The effects were assessed by the Parent ADHD rating scale and the Teacher rating scale at 2, 4, 6 and 8 weeks. In both scales a significant decrease in the scores was seen at all times points for passionflower herb as compared to baseline ($p<0.05$ to 0.001). For methylphenidate the decrease was significant from week 4 ($p<0.05$ to 0.001) compared to baseline. No significant differences were observed between the passionflower herb and methylphenidate groups [Akhondzadeh 2005].

In a randomized, double-blind, placebo-controlled study, 30 female and 30 male patients undergoing ambulatory inguinal surgical hernia repair (herniorrhaphy) received either 500 mg of a preparation (not further specified) or placebo as premedication 90 min before surgery. Anxiety and sedation were assessed 10, 30, 60 and 90 min after premedication. The Trieger Dot Test and the Digit-Symbol Substitution Test were used for the assessment of the psychomotor function at arrival in the operating room as well as 30 and 90 min after tracheal extubation. The time between arrival in the anaesthetic recovery room and discharge was recorded. Compared with placebo, the oral pre-treatment with verum resulted in a significant ($p<0.001$) decrease in anxiety levels with the onset and peak effect at 10 and 30 min respectively. All other assessed parameters did not show any significant difference [Movafegh 2008].

Patients (8 female, 52 male) scheduled for inguinal herniorrhaphy under spinal anaesthesia were enrolled in a prospective, randomized, double-blind, placebo-controlled study. Thirty minutes before spinal anaesthesia, haemodynamic parameters, STAI scores, the sedation score and psychomotor function were assessed and the patients received either a preparation (700 mg passionflower herb / 5 mL aqueous extract; not further specified) or placebo. Just before spinal anaesthesia, the tests were repeated and haemodynamics, sedation score, sensory-motor block and side effects were controlled during the operation. Psychomotor function tests were repeated at the end and 60 min after the operation. A significant increase in the STAI anxiety scores ($p<0.01$ and 0.001 respectively) was observed in the placebo group just before spinal anesthesia as compared to baseline. In the verum group no change in anxiety scores occurred. No differences between the groups were seen for all other parameters [Aslanargun 2012].

Patients (39 female, 24 male) undergoing planned dental treatment received either 20 drops of a preparation (not further specified), or a placebo or no pre-treatment the night before and a further 20 drops the following morning at least 90 min before treatment. Anxiety was measured using a VAS. With verum a significant ($p<0.001$) decrease from 12.1 points to 8.5 points was observed as compared to placebo and no pre-treatment [Kaviani 2013].

In a multicenter, prospective, non-interventional trial the effects of a dry ethanolic extract (50% ethanol; DER 5-7:1; 425 mg; 3 times daily for 12 weeks) on stress resistance (resilience) and quality of life (QoL) in patients (115 female, 38 male) with nervous restlessness were studied. Standardised questionnaires were used to evaluate resilience (RS-13), QoL (EQ-5D including EQ-VAS) and addiction potential (BDEPQ). After 12 weeks, significant ($p<0.001$) improvements in resilience from 52.1 to 67.7 points and QoL from 47.9 to 75.0 points, as well as of all accompanying symptoms such as felt restlessness, sleep disturbance, exhaustion, fear, lack of concentration, transpiration, nausea, trembling and palpitation were observed and the mean BDEPQ score was significantly ($p<0.001$) reduced from 23.0 to 19.3 points [Gibbert 2017].

In a double-blind, randomized and parallel group study, patients undergoing planned inguinal herniorrhaphy received either 500 mg of a preparation (not further specified; 30 female, 38 male) or 10 mg of oxazepam (24 female, 36 male) as a premedication 90 min before surgery. Anxiety was assessed with a numerical rating scale (NRS) both before and 90 min after the premedication. Psychomotor function was evaluated with Trieger Dot Test and the Digit-Symbol Substitution Test at arrival in the operating room and 90 min after tracheal extubation. At 90 min a significantly ($p<0.001$) better result in the NRS anxiety score was seen in the passiflora group (4.4±1.2) as compared to oxazepam (6.1±1.3). No significant differences were observed in the psychomotor function scores. Recovery of these scores was comparable in both groups reaching baseline values 90 min after extubation [Azimaraghi 2017].

A double-blind, randomized, placebo-controlled study investigated the effects of an extract (60% ethanol, leaves and fruits 8:2) in patients with insomnia disorder according to the Diagnostic and Statistical Manual of Mental Disorders (DSM-5). The two groups received either 60 mg of the extract (27 female, 18 male) or placebo (23 female, 16 male) every night for two weeks. The total sleep time significantly ($p<0.05$) increased in the verum group as compared to placebo. No differences between the groups were observed in sleep efficiency, sleep latency, total arousal number, wake after sleep onset, subjective sleep parameters and scores for depression, anxiety and stress. However, in the verum group significant improvements of sleep efficiency, wake after sleep onset as well as of scores for depression, anxiety and stress were seen as compared to baseline ($p<0.002$ to $p<0.025$) [Lee 2020].

Pharmacokinetic properties
In subcellular systems with human liver microsomes and a human liver S9 fraction containing microsomal and cytosolic fractions including important phase I and II enzymes, the metabolism of orientin, isoorientin, schaftoside, isoschaftoside, vitexin, and isovitexin was investigated. Orientin and isoorientin were metabolized to several mono-glucuronidated and mono-sulphated compounds, vitexin and isovitexin only to mono-glucuronides. The major metabolite of isoorientin was isoorientin-3'-*O*-α-glucuronide. For schaftoside and isoschaftoside, no phase I or II metabolites were identified [Tremmel 2021a].

In a Caco-2 cell monolayer model these six flavonoids underwent various metabolism pathways. At 10 and 100 µM, vitexin, schaftoside and isoschaftoside showed very limited metabolism with only hydroxylated/methoxylated glycosylflavonoids as metabolites. In contrast, orientin, isoorientin and isovitexin resulted in more phase I and II metabolites at 10 µM including sulphates as conjugation products and at 100 µM the diversity of metabolites further increased with sulphates and glucuronides [Tremmel 2021b].

Preclinical safety data

Single dose toxicity
No acute toxicity was observed in mice after i.p. administration of extracts in doses up to 500 mg/kg b.w. [Aoyagi 1974] and 900 mg/kg b.w. [Speroni 1988] as well as after oral administration of a methanolic leaf extract at doses between 50 and 1600 mg/kg [Gupta 2012].

Repeated dose toxicity
No change compared to control animals was observed in weight, rectal temperature and motor coordination of male Sprague-Dawley rats following 21 days of subacute oral treatment with 10 mL/kg b.w. of a hydroethanolic extract, equivalent to 5 g/kg b.w. of the drug [Sopranzi 1990].

An extract (60% ethanol, leaves and fruits 8:2) was administered orally to C57BL/6 mice at 500 mg/kg b.w. daily for 5 days. No differences in body weight, food and water consumption or body composition were observed as compared to the vehicle control [Kim 2019a].

Mutagenicity
In the somatic segregation assay in the diploid strain *Aspergillus nidulans* D-30, no genotoxic effects (neither chromosomal damage caused by aneuploidy and clastogenic effects nor mitotic crossover) were detected after plate incorporation of 1.30 mg/mL of a fluid extract (16.2% dry matter, 0.32% ethanol) [Ramos Ruiz 1996].

Clinical safety data
In children with attention deficit hyperactivity disorder receiving 0.04 mg/kg b.w./day of a preparation (not further specified) (n=17) or 1 mg/kg b.w./day methylphenidate (n=17) for 8 weeks, a few adverse reactions such as palpitations, weight loss, dry mouth, constipation, headache, early awakening and difficulty in falling asleep were observed in both groups. The number of events was higher in the methylphenidate group with 35 events as compared to 11 events in the passionflower herb group. With regard to decreased appetite and anxiety/nervousness, passionflower herb was tolerated significantly better ($p<0.03$ and 0.01 respectively) [Akhonzadeh 2005].

In a multicenter, prospective, non-interventional trial with a dry ethanolic extract (50% ethanol; 5-7:1; 425 mg; 3 times daily for 12 weeks) tolerability was rated as very good or good by more than 99% of the patients (n=153). Three cases of tiredness were reported [Gibbert 2017].

In a double-blind, randomized, placebo-controlled study with an extract (60% ethanol, leaves and fruits 8:2) in patients with insomnia disorder no adverse events occurred in the verum group (n=45) and laboratory results were all in the normal ranges [Lee 2020].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (well-established use) or on experience and historical use of that product (traditional use) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

Pelargonium Root

DEFINITION

Dried, unpeeled, usually fragmented, underground organs of *Pelargonium sidoides* DC and/or *Pelargonium reniforme* CURT. It contains not less than 2.0 per cent of tannins, expressed as pyrogallol ($C_6H_6O_3$; Mr 126.1) (dried drug).

The material complies with the monograph of the European Pharmacopoeia [Pelargonium root].

CONSTITUENTS

Oligomeric and polymeric proanthocyanidins (mainly with catechin and gallocatechin units, approx. 9%); flavan-3-ols (afzelechin, catechin and gallocatechin); phenolic acids (gallic acid and its methylester); hydroxycinnamic acids (caffeic acid, *p*-coumaric acid); flavonoids (*P. reniforme*); highly oxygenated coumarins (approx. 0.05% for *P. sidoides* and 0.03% for *P. reniforme*) such as 7-hydroxy-5,6-dimethoxycoumarin (umckalin), 5,6,7-trimethoxycoumarin (TMC), 5,6,7,8-tetramethoxycoumarin and 6,8-dihydroxy-5,7-dimethoxycoumarin (DHDMC) (all characteristic for *P. sidoides*), 6-hydroxy-5,7-dimethoxycoumarin (fraxinol), 8-hydroxy-6,7-dimethoxycoumarin (fraxidin) and 5,6-dihydroxy-7-methoxycoumarin (isofraxetin) (characteristic for *P. reniforme*), 8-hydroxy-5,6,7-trimethoxycoumarin and 6,7,8-trihydroxycoumarin (present in both species), *P. sidoides* contains also coumarins as glycosides and sulfates [Kolodziej 1995,1998,2000,2003b, 2007, Kayser 1995, Latté 2000, Schoetz 2008].

CLINICAL PARTICULARS

Therapeutic indications
Symptoms of upper respiratory tract infections including common cold, such as blocked or runny nose, sore throat and cough [Timmer 2013, Kamin 2010a-b, Brendler 2009, Bachert 2009, Agbabiaka 2008, Matthys 2010a/2007c/2003, Lizogub 2007, Chuchalin 2005, Bereznoy 2003].

Posology and method of administration

Dosage

Ethanolic extract (1:8-11; 12% V/V)
Adults and children over 12 years: 2.5-7.5 mL daily [Timmer 2013, Kamin 2010a, Brendler 2009, Bachert 2009, Agbabiaka 2008, Matthys 2007b-c/2003, Lizogub 2007, Chuchalin 2005, Heil 1994].
Children aged 6-12 years: 1.25–2.5 mL daily [Timmer 2013, Kamin 2010a, Brendler 2009, Agbabiaka 2008, Matthys 2007b, Bereznoy 2003, Haidvogl 1996, Heil 1994].
Children aged 2-6 years: 0.6-1.25 mL daily [Timmer 2013, Kamin 2010a, Brendler 2009, Agbabiaka 2008, Matthys 2007b, Haidvogl 1996, Heil 1994].

Method of administration
For oral administration.

Duration of administration
If symptoms persist or worsen, medical advice should be sought.

Contra-indications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

E/S/C/O/P MONOGRAPHS

Pregnancy and lactation
No data available.

In accordance with general medical practice, the product should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Gastro-intestinal complaints and allergic skin reactions [Agbabiaka 2008, Timmer 2013, Brendler 2009, Brown 2009]. Hepatotoxicity has been reported but causality for pelargonium could not be established [Teschke 2012a and 2012b].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Almost all pharmacodynamic and clinical studies were performed with an ethanolic extract of *P. sidoides* root (1:9-11 or 1:8-10; 11% ethanol (m/m)) as an 80:20 mixture with glycerol 85%; this will be subsequently cited as the liquid extract.

Pharmacodynamic properties

In vitro experiments

Antibacterial effects
Methanolic extracts of the roots showed antibacterial activity against 8 bacteria: *Staphylococcus aureus* (Sa), *Streptococcus pneumoniae*, β-haemolytic *Streptococcus, Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, Pseudomonas aeruginosa* and *Haemophilus influenzae* (MIC values: 5 – 7.5 mg/mL). The ethyl acetate, butanol and remaining water fractions of these extracts gave MIC values from 0.6 to 2.5 mg/mL. From the 7 isolated compounds umckalin and DHDMC were the most potent (MIC values: 0.2-0.5 mg/mL) [Kayser 1997].

The liquid extract demonstrated antibacterial activity against several multiresistant strains of Sa (MIC 3.3 mg/mL). An 80% acetone extract (4:1; 12.5 µg/mL) inhibited the growth of *Mycobacterium tuberculosis* by 96% in the radiospirometric bioassay. In the Alamar blue assay the same extract exhibited an MIC of 100 µg/mL (compared to rifampicine MIC 0.06 µg/mL) [Kolodziej 2003a].

The liquid extract reduced the growth of *Helicobacter pylori* by 43% of the control value at a concentration of 100 µg/mL. The extract (50 and 100 µg/mL) significantly reduced ($p<0.05$) the quantity of bacteria attached to gastric epithelial AGS cells by 77% and 91% respectively; while amoxicillin (up to 64 µg/mL) was inactive. At the same concentrations the adherence to these cells was significantly reduced ($p<0.05$) [Beil 2007].

The same extract significantly reduced adhesion of *Streptococcus pyogenes* (Sp) to human Hep-2 epithelial cells dose-dependently by up to 46% ($p<0.001$) while the adhesion to decaying buccal epithelial cells was increased by 7-fold ($p<0.001$) [Conrad 2007b].

In another experiment the extract also inhibited the adhesion of Sp to Hep-2 cells but the polyphenol-free extract was inactive. When highly purified proanthocyanidin fractions from *P.sidoides* were evaluated, only the prodelphinidins showed anti-adhesive properties [Janecki 2011].

Immunomodulatory properties
A methanolic extract, as well as petrol ether, ethyl acetate and butanol fractions thereof, reduced the intracellular survival of *Leishmania donovani* amastigotes within murine macrophages (EC_{50} 2.7, <0.1, <0.1 and 3.3 µg/mL respectively). A bioassay-guided isolation led to the characterization of gallic acid and its methyl ester with EC_{50} values of 4.4 and 12.5 µg/mL (compared to the reference sodium stibogluconate, EC_{50} 2.7 µg/mL). Isolated coumarins proved to be inactive at concentrations up to 25 µg/mL. This was possibly due to macrophage activation which was confirmed by detection of TNF-α and NO-inducing activity. The most potent NO inducers were gallic acid, umckalin and DHDMC (35-45% of the effect of LPS), whereas gallic acid and its methyl ester exhibited the strongest TNF-α-inducing potential (24 and 19% of LPS stimulus). Gallic acid also showed an interferon-like activity by reducing the cytopathogenic effect of encephalomyocarditis virus in fibroblasts [Kayser 2001].

The liquid extract (1 – 30 µg/mL) dose-dependently increased the release of NO, IL-1, IL-12 and TNF-α and changed the expression of the surface markers CD40 and CD119 in bone-marrow derived macrophages infected with *Listeria monocytogenes* [Thäle 2008].

The liquid extract (3 µg/mL) increased β-interferon secretion in MG-63 cells by 200% [Kolodziej 2003a].

Cytotoxic effects
In the brine shrimp lethality bioassay, neither pelargonium extracts nor phenolic constituents such as benzoic and cinnamic acid derivatives, hydrolysable tannins and C-glycosylflavones showed cytotoxic effects (LC_{50} > 1 mg/mL for the extracts; LC_{50} > 0.2 mg/mL for the pure compounds) [Kolodziej 2002].

The cytotoxicity of scopoletin, umckalin and DHDMC was evaluated in a human small cell lung carcinoma line and in a human colorectal cancer cell line, using the micro culture tetrazolium assay. Only DHDMC showed a moderate cytotoxicity with IC_{50} values of 22.1 and 9.5 µM respectively (compared to cisplatin: IC_{50} of 1.0 and 2.7 µM respectively) [Kolodziej 1997].

Other effects
The liquid extract showed a dose-dependent anti-influenza virus activity with an EC_{50} of 6.6 µg/mL and corresponding to a selectivity index of 84 (CC_{50}/ EC_{50}). The concentrations required for complete virus clearance (determined on 6 different strains) varied from 16 µg/mL up to 300 µg/mL. It was demonstrated that the extract had no virucidal activity but affected an early step in the virus life cycle (presumably viral entry into the host cell). A polyphenol-free extract had no activity while an oligo-/polymeric prodelphinidin fraction had a EC_{50} of 2.8 µg/mL [Theisen 2012].

The extract exhibited a free radical scavenging activity in the DPPH assay (IC_{50} 14.7 ± 0.85 µg/mL) (Rezaizadehnajafi 2014).

The liquid extract (30 µg/mL) enhanced phagocytosis by 56% at 2 min ($p=0.002$) and oxidative burst (maximum increase of 120% after 4 min, $p<0.001$). The extract also enhanced intracellular killing, demonstrated by a significant reduction of surviving *Candida albicans* cells (maximum reduction of 31% after 120 min, $p<0.001$) [Conrad 2007a].

The liquid extract significantly ($p<0.05$) increased the ciliary beat frequency in human nasal epithelium cell cultures to 123% at 30 µg/mL and to 133% at 100 µg/mL, compared to the equilibration phase (100%) [Neugebauer 2005].

In vivo experiments
The liquid extract administered by inhalation to influenza-infected mice for 10 days significantly ($p<0.003$) increased survival without obvious toxicity (no difference in weight of lungs, liver, spleen and kidneys) [Theisen 2012].

In nematodes (*Caenorhabditis elegans*) pre-treated with 40, 50 and 100 µg/mL of the extract for 48 h before the addition of 20 µM juglone, a significant reduction (32% to 58%; $p<0.001$) in hsp-16.2::GFP activity (induced by oxidative stress) was observed as compared to controls. The same doses of the extract significantly increased the survival rate (22 – 24%; $p<0.05$) in the nematodes after the addition of a lethal dose of 300 µM juglone for 24 h. Application of the extract (50 µg/mL) to TJ356 worms induced the migration of the transcription factor DAF-16 from cytosol to the nucleus (this is essential for the activation of the transcription of various genes mediating stress resistance) [Rezaizadehnajafi 2014].

Pre-treatment of mice with a single oral dose of liquid extract (400 µg/kg b.w.) significantly inhibited lipopolysaccharide-induced sickness behaviour ($p<0.05$) [Noldner 2007].

Studies in humans
All studies were performed with the liquid extract except a few where it was dried but no DER is given for the dry extract.

Pharmacological studies in humans
In a randomized, double-blind, placebo-controlled study 28 athletes received the liquid extract (4.5 mL daily) or placebo for 28 days. The relative salivary IgA level was significantly increased in the verum group ($p<0.001$) while nasal IL-15 ($p<0.05$), serum IL-15 ($p<0.02$) and serum IL-6 levels ($p<0.05$) were significantly decreased [Luna 2011].

Clinical Studies
In a systematic review and meta-analysis, 6 randomized clinical trials (Matthys 2003, Chuchalin 2005, Matthys 2007c, Blochin and 2 unpublished trials) met the inclusion criteria, of which 4 were suitable for statistical pooling. Only mono-preparations containing the liquid extract used for the treatment of patients with acute bronchitis were included. Meta-analysis of the 4 placebo-controlled trials indicated that pelargonium significantly decreased the Bronchitis Severity Score (BSS assessing cough, sputum, rales/rhonchi, chest pain during coughing and dyspnoea) within 7 days of treatment (weighted mean difference: 2.80 points, 95% CI interval 2.44-3.15) [Agbabiaka 2008].

A Cochrane review evaluated 10 randomized clinical trials dealing with acute bronchitis in adults and children, sinusitis and the common cold in adults, and sore throat in children. The quality of 8 of the 10 studies was considered to be adequate for inclusion in the analysis (Chuchalin 2005, Matthys 2007c, Matthys 2010a, Lizogub 2007, Bachert 2009, Kamin 2010a, Kamin 2010b and Kamin 2012). It was concluded that based on the limited evidence from the few clinical trials with acceptable methodology, pelargonium may offer symptom relief in acute bronchitis in children and adults, and in rhinosinusitis and the common cold in adults [Timmer 2013].

Other clinical reviews, which assessed open as well as controlled studies, involved a total of 5400 patients. They all concluded that pelargonium is efficient in the treatment of upper respiratory tract infections [Brown 2009, Brendler 2009, Kolodziej 2002].

Acute bronchitis
In two randomized, double-blind, placebo-controlled, multicentre trials, patients (1-18 years) with acute bronchitis received the liquid extract (1-6 years: 3x0.5 mL; 6-12 years: 3x1 mL; 12-18 years: 3x1.5 mL daily) or placebo for 7 days. From baseline to day 7, the decrease in the BSS total score was significantly higher for the verum group compared to placebo:
- *Study 1* (n=200): 3.4±1.8 points versus 1.2±1.8 points ($p<0.0001$) [Kamin 2010a].
- *Study 2* (n=220): 4.4±1.6 points versus 2.9±1.4 points ($p<0.0001$) [Kamin 2012].

Treatment outcome and satisfaction with treatment were also significantly better compared to placebo ($p<0.0001$).

In three randomized, double-blind, placebo-controlled, multicentre studies patients with acute bronchitis received the liquid extract (1.5 mL 3 times daily) or placebo for 7 days. In all studies the decrease of BSS from baseline to day 7 was significantly higher for the verum group compared to placebo:
- *Study 1* (n=217): 7.6±2.2 points versus 5.3±3.2 points; $p<0.0001$ [Matthys 2007c]
- *Study 2* (n=124): 7.2±3.1 points versus 4.9±2.7 points; $p<0.0001$ [Chuchalin 2005]
- *Study 3* (n=468): 5.9±2.9 points versus 3.2±4.1 points; $p<0.0001$ [Matthys 2003]

In addition, the duration of illness was shorter and satisfaction with treatment was better with verum compared to placebo.

In a prospective, open, multicentre study, 205 patients (42±16 years) suffering from acute bronchitis, or an acute exacerbation of chronic bronchitis, were treated with 1.5 mL of the liquid extract, three times daily for 7 days. The total BSS decreased by 3.3±3.8 points and 60.5% of the patients assessed their health condition at the end of the study as much improved or free from symptoms [Matthys 2007a].

In a prospective, open, multicentre study, 2099 patients (<3 years: n = 78; 3-18 years: n = 420; >18 years: n = 1601) with acute bronchitis were treated with the liquid extract at an age-dependant dosage three times daily for a maximum of 14 days (<6 years: 0.5 mL; 6-12 years: 1 mL; >12 years: 1.5 mL). The mean BSS of all patients decreased from 7.1±2.9 points at baseline to 1.0±1.9 points at patient's last visit. Subgroup analysis for children (<18 years, n = 498) and infants (<3 years) showed a decrease in mean BSS from 6.3±2.8 to 0.9±1.8 points and from 5.2±2.5 to 1.2±2.1 points, respectively [Matthys 2007b].

A prospective, open, multicentre study evaluated the treatment of 742 patients (<12 years) with acute bronchitis or acute exacerbations of chronic bronchitis. The children were treated with the liquid extract at a dosage according to their age for a maximum of 2 weeks: <2 years 0.75 mL daily, 2-6 years 1.5mL daily and 6-12 years 3 mL daily. The overall BSS decreased significantly from 6.0±3.0 points to 1.4±2.1 points ($p<0.001$). The assessment of the individual symptoms (coughing, expectoration, difficulty in breathing, wheezing and chest pain) gave a response rate (remission and improvement) of more than 80% [Haidvogl 1996]. In a similar study with 259 children and the same treatment, all the individual symptoms showed remission or improvement rates of more than 80% [Dome 1996].

In a randomized, double-blind, placebo-controlled, dose-finding study, 400 patients (6-18 years) with acute bronchitis received either 30 mg, 60 mg or 90 mg of the dry extract or placebo daily for 7 days. The decrease of total BSS from baseline to day 7 was significantly higher for the verum groups (60 mg, $p=0.0004$; 90 mg, $p<0.0001$) compared to placebo (4.4±2.4 and 5.0±1.9 points respectively versus 3.3±2.6 points) without relevant differences between these 2 verum dosages [Kamin 2010b].

In a randomized, double-blind, placebo-controlled, multicentre, dose-finding trial, 406 patients (>18 years) with acute bronchitis

received either 30 mg, 60 mg or 90 mg of the dry extract or placebo daily for 7 days. The decrease of total BSS from baseline to day 7 was significantly higher for the verum groups ($p<0.0001$) compared to placebo (4.3±1.9, 6.1±2.1 and 6.3±2.0 points respectively, versus 2.7±2.3 points) without relevant differences between the 2 highest dosages [Matthys 2010a]. The HRQL (health-related quality of life) and PRO (patient-reported outcome) questionnaires, assessing the secondary outcome measures, demonstrated significantly ($p<0.05$ or $p<0.0001$) greater improvement in all three of the verum groups compared to placebo (physical score, impact of patient's sickness, duration of activity limitation, patient-reported treatment outcome, satisfaction with treatment) [Matthys 2010b].

According to two reviews, other studies also showed an improvement of the BSS with the liquid extract given at an age-dependant dosage three times daily (<6 years: 0.5 mL; 6-12 years: 1 mL; >12 years: 1.5 mL) [Kolodziej 2003b; Brendler 2009].

TABLE 1. Clinical and surveillance studies in patients with acute bronchitis (Kolodziej 2003b)

Number of patients	Duration (days)	Control	BSS decrease after treatment	
			Verum	Control
205 adults	7	placebo	7.7 points	5.3 points
220 adults & children	7	placebo	4.4 points	2.9 points
60 children (6-12 y.)	7	AcC	7[1] points	6[1] points
213 children (6-12 y.)	7	AcC	6.7 points	6.6 points
205 adults	7	-	3.3 points	-
1042 children (up to 12 y.)	14	-	5.4 points	-

AcC = acetylcystein

[1] result given as such in Kolodziej 2003b

Chronic bronchitis
In a randomized, double-blind, placebo-controlled trial, 200 patients (> 18 years) with a history of chronic bronchitis were allocated to a 24-week add-on therapy with 1.5 mL of the liquid extract 3 times daily or placebo, alongside a standardised baseline-treatment. Median time to exacerbation was significantly ($p=0.005$) prolonged with verum compared to placebo (57 versus 43 days). Analysis of the secondary endpoints showed fewer exacerbations, less patients with antibiotic use, improved quality of life and less days of inability to work [Matthys 2013].

Tonsillopharyngitis
In a randomized, double-blind, placebo-controlled trial, 143 patients (6-10 years) with acute non-group A β-haemolytic *Streptococcus* tonsillopharyngitis received the liquid extract (3 mL daily) or placebo for 6 days. The decrease of the Tonsillopharyngitis Severity Score (TSS: assessing sore throat, difficulty in swallowing, pharyngeal erythema and fever) from baseline to day 4 was significantly higher for the verum group compared to placebo (7.1±2.1 points versus 2.5±3.6 points; $p<0.0001$). Also, the severity of the symptoms was reduced and the duration of illness was shortened by at least 2 days [Bereznoy 2003].

According to two reviews, other studies also showed an improvement of the TSS with the liquid extract given in a dosage of 1 mL three times daily [Kolodziej 2003b; Brendler 2009].

TABLE 2. Clinical and surveillance studies in patients with acute tonsillopharyngitis (Kolodziej 2003b)

Number of patients	Duration (days)	Control	TSS decrease after treatment	
			Verum	Control
124 children (6-10 y.)	6	placebo	6.8 points	3.4 points
78 children (6-10 y.)	6	placebo	6.7 points	3.6 points
60 children (6-10 y.)	10	gargle	5[1] points	3[1] points
1000 (2-35 years)	7	-	11[1] points	-

[1] result given as such in Kolodziej 2003b

Rhinosinusitis
In a randomized, double-blind, placebo-controlled, multicentre trial, 103 patients (18 – 60 years) with acute rhinosinusitis received the liquid extract (3 mL three times daily) or placebo for a maximum of 22 days. From baseline to day 7, the mean decrease in Sinusitis Severity Score (SSS; headache, maxillary pain, nasal obstruction and purulent nasal secretion) was 5.5 points in the verum group compared to 2.5 points in the placebo group ($p<0.00001$). Analysis of the secondary outcome measures showed a remission or major improvement in 30% of the patients in the verum group, compared to 5.8% in the placebo group ($p<0.0001$) [Bachert 2009].

In a randomized, double-blind, placebo-controlled trial, 272

patients with acute sinusitis were treated with 3 mL of the liquid extract three times daily or placebo for a maximum of 3 weeks. In the verum group, the mean SSS decreased from 14.4±1.8 points at baseline to 7.4±3.2 points at the patient's last visit, while the baseline value of 13.9±1.7 points in the placebo group remained unchanged ($p<0.0001$) [Bachert 2005 in Brendler 2009].
