Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

Front cover
Title page
Verso
Foreword and Preface
Notes for the Reader
Abbreviations
The monograph text

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

AGRIMONIAE HERBA

2019

Agrimony

DEFINITION

Agrimony consists of the dried flowering tops of *Agrimonia eupatoria* L. It contains not less than 2.0 per cent of tannins, expressed as pyrogallol ($C_6H_6O_3$; Mr 126.1) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Agrimony].

CONSTITUENTS

The main characteristic constituents are tannins (3-11%), consisting mainly of proanthocyanidins (condensed tannins) with a small proportion of ellagitannins, of which agrimoniin is the main constituent (0.3-0.5%) [Von Gizycki 1950; Drozd 1983; Granica 2013].

Flavonoids (about 0.9%) [Carnat 1991; Granica 2013] including glycosides of quercetin, the 7-glucosides of luteolin and apigenin [Von Gizycki 1950; Ivanov 1970; Sendra 1972; Gorunovic 1989; Carnat 1991] and 3-glycosides of kaempferol and kaempferide [Bilia 1993a,1993b], as well as triterpenoids such as ursolic acid [Le Men 1995], euscapic acid and the 28-glucosyl esters of euscapic acid and tormentic acid [Bilia 1993b].

Other constituents include phenolic acids [Bucková 1972; Granica 2013], β-sitosterol [Bilia 1993a], polysaccharides (19.5%) [Drozd 1983; Krzaczek 1985], and minerals (7.3-7.9%) [Von Gizycki 1950; Carnat 1991; Szentmihályi 1998].

CLINICAL PARTICULARS

Therapeutic indications

Internal use
Agrimony has been widely documented as a remedy to treat mild diarrhoea [Agrimonia; Blaschek 1993; Dorsch 2002].

External use
Locally as a gargle for inflammation of the oral and pharyngeal mucosa [Gray 1998; Dorsch 2002] and as a compress or rinse to support the healing of wounds [Gorunovic 1989; Blaschek 1993].

Efficacy for these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Internal use

Adults: 3-12 g of dried herb daily, or as an infusion or equivalent preparation [Blaschek 1993; Dorsch 2002]; three times daily, 1-3 mL of a liquid extract (1:1 in 25% ethanol) or 5-10 mL of a tincture (1:5 in 45% ethanol) [Gray 1998].

Children, average daily dose: *1-4 years of age*, 1-2 g; *4-10 years of age*, 2-3 g; *10-16 years of age*, 3-6 g [Agrimonia].

External use
A 10% decoction used several times daily, locally in gargles or externally as a compress or rinse [Dorsch 2002].

Method of administration
For oral administration or external use.

E/S/C/O/P
MONOGRAPHS

Duration of administration
No restriction.
If symptoms persist or worsen, medical advice should be sought.

Contra-indications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No human data available. In accordance with general medical practice, the product should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None known.

Overdose
None known.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments
A hydroethanolic extract (2.5 g drug/100 mL, ethanol 50% V/V) showed strong elastase-inhibiting activity [Carnat 1991].

A dried hydromethanolic extract (50% V/V) showed no spasmolytic activity on spontaneous or induced contractions of isolated guinea-pig ileum at concentrations up to 800 µg/mL [Izzo 1996].

A decoction (1 mg/ml) stimulated 2-deoxyglucose transport (1.4-fold), glucose oxidation (1.4-fold), glycogenesis (2.0-fold) and lactate release (1.4 fold) in isolated mouse abdominal muscle, comparable to the effects evoked by 0.01 µM insulin. The activity of agrimony on insulin secretion was also evaluated. A decoction (0.25-10 mg/ml) evoked a stepwise 1.9- to 3.8-fold stimulation of insulin secretion from the BRIN-BD11 rat pancreatic B-cell line with no detrimental effect on cell viability. These experiments demonstrated that agrimony has antihyperglycaemic, insulin-like and insulin-releasing activity [Gray 1998].

An infusion (1 g agrimony/200 mL water) demonstrated considerable antioxidant activity. Relative to the reactivity of Trolox (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid) as a standard, the Trolox equivalent antioxidant capacity (TEAC) was found to be 3.76 mM [Ivanova 2005].

Aqueous extraction of agrimony aerial parts was performed at four different temperatures in order to determine the optimal extraction temperature for inhibiting the release of hepatitis B surface antigen (HBsAg) from hepatitis B virus-infected HepG2.2.15 cells. Secretion was inhibited dose-dependently and the EC_{50} values for each aqueous extract at 37 °C, 45 °C, 55 °C and 60 °C were 168 µg/mL (extrapolated value), 127.91 ± 4.21 µg/mL, 115.24 ± 4.75 µg/mL and 74.29 ± 41.97 µg/mL respectively. Cell growth was not influenced by treatment with the aqueous extracts at concentrations of 44–132 µg/mL. The inhibitory activity of the extracts on HBsAg secretion varied over the growing season and was the highest at mid-July [Kwon 2005].

An aqueous extract significantly ($p<0.001$) suppressed lipopolysaccharide-induced nitric oxide production in BV2 microglial cells at concentrations of 0.01, 0.1 and 1 mg/ml compared to control. The extract at the same concentrations also significantly ($p<0.05$ to 0.001) suppressed lipopolysaccharide-induced production of the proinflammatory cytokines tumor necrosis factor, interleukin 1 beta and interleukin 6, and inhibited the expression of inducible nitric oxide synthase, in a dose-dependent manner [Bae 2010].

A methanolic extract (80%) and *n*-hexane, BuOH, EtOAc and H_20 fractions significantly attenuated glutamate-induced oxidative stress in HT22 hippocampal cells. Isolated flavonoids also showed a neuroprotective effect on glutamate-induced toxicity in HT22 cells [Lee 2010].

An ethanolic extract (45%; DER 1:2) demonstrated high growth inhibition against *Helicobacter pylori* and *Campylobacter jejuni*. At a dilution of 1:25 the % of inhibition ± SD against *H. pylori* was 97 ± 5 % and against *C. jejuni* was 96 ± 30%. At a dilution of 1:100, results were 5 ± 11 % and 30 ± 37% respectively [Cwikla 2010].

No significant antiadhesion activity (IC_{50} values >35 mg/mL) against *Campylobacter jejuni* was found for a hydroethanolic extract [Bensch 2011].

A lyophilized infusion prepared according to the Pharmacopoeia Bohemoslovaca 4 did not demonstrate cytotoxic activity at the tested concentrations (0.1 mg/mL and 0.05 mg/mL) on a THP-1 cell line after 24 h incubation. The infusion did not alter CAT activity but did decrease the activity of SOD. Good antioxidant activity was shown in the ABTS assay (RC_{50}: 0.79 mg/mL). Further antioxidant properties were shown in a test assessing plasmid DNA protection and the infusion had a lower damage index than the standard rutin [Kuczmannová 2015].

Various extracts were obtained by macerating 30 g of agrimony in 150 mL of a range of solvents, namely ethanol, diethyl ether, water and acetone. The following dried extracts were obtained: 5.42 g of water extract, 0.55 g of diethyl ether extract, 0.76 g of acetone extract and 2.4 g of ethanol extract. The acetone extract (at 250 µg/mL) exhibited the greatest DPPH radical scavenging activity (97.13%), while the water and ethanol extracts also exhibited high antioxidant activity. The strongest antimicrobial activity was detected against gram positive bacteria, with the acetone extract demonstrating the highest activity. BIC_{50} (inhibitory concentration to reduce biofilm coverage by 50%) values for the acetone extract were 4315 µg/mL for *P. mirabilis* and 4469.5 µg/mL for *P. aeruginosa* [Muruzović 2016].

An infusion (20 g agrimony/600mL water, for 15 min) and its ethyl acetate fraction showed considerable antioxidant activity when calculated relative to the reactivity of DPPH as standard, with respective EC_{50} values of 12.80 µg/mL and 4.60 µg/mL. The EC_{50} values for superoxide anion scavenging activity were 3.34 µg/mL for the infusion and 13.59 µg/mL for the fraction. Respective EC_{50} values for hydroxyl radical-scavenging activity were 126.99 µg/mL and 90.97 µg/mL. In experiments assessing cytotoxicity and effects on NO production, RAW 264.7 macrophages were incubated for an hour with various concentrations of the infusion and fraction and then with LPS for 24 hours. Cell viability of the macrophages (measured as % of LPS) was only significantly ($p<0.001$) reduced by the highest concentrations tested of the infusion (770 µg/mL) and fraction (276 µg/mL). LPS-induced increases in nitrite production (% of LPS) were only

significantly ($p<0.001$) inhibited, without detrimental effects to cells, by the infusion at 382 µg/mL and the fraction at 138 µg/mL. In a further experiment assessing NO production, cells were cultured with S-nitroso-N-acetylpenicillamine (SNAP). The infusion significantly ($p<0.05$) inhibited nitrite production (% of SNAP) by 36.67% at 382 µg/mL and the fraction by 29.46% at 138 µg/mL [Santos 2017].

In vivo experiments

After oral administration of an infusion or decoction to rats at a dose equivalent to 3 g dried herb per kg b.w., the volume of urine excreted over the following 6 hours was significantly ($p<0.01$) less than that from rats treated with distilled water, while the amount of uric acid excreted in the urine during the first 4 hours was significantly ($p<0.01$) greater than (more than two-fold) that of rats treated with distilled water, suggesting a uricosuric effect. The amount of urea excreted remained largely unchanged [Giachetti 1986]. Further experiments with rats showed that, while diuresis resulting from distilled water provoked loss of electrolytes, agrimony compensated for electrolyte loss, particularly that of potassium [Giachetti 1989].

Induction of diabetes in mice by treatment with streptozotocin (STZ) led, after 20 days, to reduced body weight ($p<0.01$) and significant increases in fluid and food intake and in plasma glucose (all $p<0.001$ compared to untreated controls). Incorporation of agrimony into the diet (62.5 g/kg in food) and drinking water (2.5 g/litre of a diluted decoction), for 5 days before and subsequent to administration of STZ, counteracted the loss of body weight to some extent and significantly counteracted polydipsia ($p<0.001$), hyperphagia ($p<0.01$) and hyperglycaemia ($p<0.05$) compared to STZ-treated mice receiving a normal diet [Swanston-Flatt 1990; Gray 1998].

A lyophilized aqueous extract (yield 17.1%), containing 8.34 and 11.82 mg/g extract of luteolin 7-glucuronide and apigenin 7-glucuronide respectively, was tested for hepatoprotective activity against chronic ethanol-induced liver injury in rats. Animals were treated orally with the extract at 10, 30, 100 and 300 mg/kg/day. The ethanol-induced increase in ALT was attenuated by the 10 and 30 mg/kg doses, while the increase in AST was attenuated by the 10, 30 and 100 mg/kg doses. Micro- and macrovesicular steatosis and excessive inflammatory cell infiltration were attenuated by the 30 mg/kg dose. The 30 mg/kg dose also had the following effects: prevented the ethanol-induced increase in serum concentrations of TNF-α and IL-6, attenuated the induced increase in CYP2E1 activity, the increase in MDA level and the decrease of GSH content, as well as the increase in hepatic level of TLR4 protein expression. It also attenuated the nuclear levels of p65, a subunit of NF-κB, and prevented the ethanol-induced increases in MyD88, COX-2, and iNOS protein expression [Yoon 2012].

An infusion prepared according to the Pharmacopoeia Bohemoslovaca 4 was provided to male Sprague-Dawley rats (n = 20; 6 months old) for 5 weeks prior to experimental skin flap surgery. The mean vital area of the skin flap 7 days after surgery was 48.7% ± 9.4% in the control group (water only), whereas the agrimony treated rats had a significantly ($p<0.05$) increased flap viability at 58.1% ± 7.7% [Kuczmannová 2015].

The antinociceptive activity of a dried ethanolic extract (500 g aerial parts macerated in a volume of 80% ethanol equal to ten times that of the sample) was investigated in a rat model of cisplatin-induced neuropathy. The effect of the extract (200 mg/kg p.o.) was compared with that of the positive control gabapentin (100 mg/kg i.p.) in various tests. Paw withdrawal duration in response to pin prick was considerably lower in the agrimony group than the cisplatin only control group at week 1 and was sustained at week 4. Gabapentin also showed a lower withdrawal duration than the cisplatin-only control group, but this effect was not sustained at week 4. Similar results were noted in the test of paw-withdrawal threshold in response to mechanically-induced pressure [Lee 2016].

An infusion (20 g agrimony/ 600mL water, for 15 min) and its ethyl acetate fraction were tested for anti-inflammatory and analgesic activity in several assays. In the carrageenan-induced rat paw oedema assay, rats were divided into six groups (n = 6–8): negative control group received water (0.5 µL/g p.o.), positive control group received diclofenac sodium (10 mg/kg i.p.), and test groups received one of two oral doses of the infusion (99.59 mg/kg, D1; 199.18 mg/kg, D2) or the ethyl acetate fraction (18.12 mg/kg, D3; and 36.24 mg/kg, D4) reconstituted in water. The infusion reduced oedema by 43.2% (D1) and 52.2% (D2) and the ethyl acetate fraction reduced it by 34.6% (D3) and 35.4% (D4) compared to the negative control.

Analgesic activity of the preparations was tested using several assays in mice. Neither preparation demonstrated a significant increase in the reaction time of mice in the hot plate test. In contrast, the preparations did inhibit abdominal writhing induced by acetic acid. Mice were divided into six groups (n = 6–8): negative control group received water (0.5 µL/g p.o.), positive control group received diclofenac sodium (10 mg/kg i.p.), and test groups received one of two oral doses of the infusion (199.18 mg/kg, D5 and 398.26 mg/kg, D6) or the ethyl acetate fraction (36.24 mg/kg, D7; 72.48 mg/kg, D8), reconstituted in water. Diclofenac sodium inhibited writhing by 71.3%, while the average number of abdominal constrictions was significantly ($p<0.05$) reduced by D5 (43.5%), D6 (49.8%), D7 (29.2%) and D8 (46.8%) compared to the negative control. Only the D8 dose was tested in the formalin test. It did not show any relevant effect in the early phase of pain response but did reduce time spent licking in the late phase by 32.5% [Santos 2017].

Pharmacological studies in humans

An infusion of the dried aerial parts (1 g in 200 ml water) was given to 19 healthy volunteers (aged 18 to 55 years) twice a day (9 am and 2 pm) for 30 days. Fasting blood samples were taken on days 0 and 30. Significant increases from baseline were found on day 30 for HDL cholesterol ($p<0.05$) and total cholesterol ($p<0.01$), while there were non-significant increases in LDL cholesterol, triglycerides and glucose; all markers remained within reference values. Total antioxidant capacity had significantly ($p<0.001$) increased at day 30. There was a significant ($p<0.05$) decrease in serum levels of the pro-inflammatory cytokine IL-6 at day 30. Plasma levels of adiponectin were not significantly changed at day 30, but were found to be positively correlated with HDL cholesterol levels [Ivanova 2013].

Clinical studies

Patients with cutaneous porphyria (n = 20) were treated orally with an infusion 3-4 times daily (and no other treatment) in an open study. After 15 days substantial improvements in skin eruptions were observed together with decreases in serum iron levels and urinary porphyrins (intensely hyperchromic urine after initial doses, decolorizing to normal over the following days). All the patients showed improvements in general health (appetite, lack of dyspepsia, regularity) and no adverse reactions were reported [Patrascu 1984].

Pharmacokinetic properties

No data available.

Preclinical safety data

Mutagenicity

In the Ames test, using *Salmonella typhimurium* strains TA98

and TA100 with and without metabolic S9 mix activation, a commercial tincture (ethanol 70%, 1:5) [Schimmer 1994] and a methanolic extract [Bilia 1993a] from agrimony did not increase the number of revertants and showed no evidence of mutagenicity.

Clinical safety data

No adverse effects were observed in the clinical study described above, in which 20 patients were treated orally with an infusion of agrimony 3-4 times daily for 15 days Patrascu 1984].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CVI	chronic venous insufficiency
CYP	cytochrome P450
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF	necrosis factor
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ORAC	oxygen radical absorbance capacity
ovx	ovariectomy or ovariectomized
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandine E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TNF	tumour necrosis factor

URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ALCHEMILLAE HERBA

2013

Alchemilla / Lady's Mantle

DEFINITION

Alchemilla consists of the whole or cut, flowering aerial parts of *Alchemilla vulgaris* L. *sensu latiore*. It contains minimum 6.0 per cent of tannins, expressed as pyrogallol ($C_6H_6O_3$; M_r 126.1) (dried drug). The material complies with the European Pharmacopoeia [EP].

Note: A synonym for *Alchemilla vulgaris* L. *sensu latiore* as stated in the European Pharmacopoeia definition is *Alchemilla xanthochlora* Rothm. [Blaschek 2009].

CONSTITUENTS

Ellagitannins (5-8%), principally the dimers agrimoniin (3.5-3.8%) and laevigatin F (0.9%) and the monomer pedunculagin (1.2%) as determined by HPLC [Geiger 1990, 1991, 1994; Moeck 2007; Bradley 2006; Blaschek 2009]. Use of the pharmacopoeial method for tannin determination yielded contents of up to 15% in the herb [Lamaison 1990; Schimmer 1992; Scholz 1994; Fraisse 1999].

Flavonol glycosides (2.2-2.5% in leaves, 1.0-1.9% in flowers), mainly quercetin 3-glucuronide, quercetin 3-glucoside (isoquercitrin), 3-rutinoside (rutin) and 3-arabinoside as well as kaempferol 3-(6″-p-coumaryl)-glucoside [Lamaison 1991; Schimmer 1992; D'Agostino 1998; Fraisse 2000; Bradley 2006, Blaschek 2009]. Approximately 3 % leucocyanidin in the flowers [Moeck 2007].

Essential oil, phytosterols and aliphatic hydrocarbons [Schimmer 1992; Bradley 2006].

CLINICAL PARTICULARS

Therapeutic indications

As an adjuvant in non-specific diarrhoea, gastrointestinal complaints and dysmenorrhoea [Schimmer 1992; Scholz 1994; Jänicke 2003; Bradley 2006; Gerlach 2007, Schilcher 2007; Moeck 2007; Blaschek 2009].

Efficacy in these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adult daily dose:

Internal use:

2-4 g of dried drug as an infusion or equivalent preparation three times daily [Schimmer 1992; Jänicke 2003; Bradley 2006; Moeck 2007; Blaschek 2009].
2-3 ml liquid extract (1:1, 25% ethanol) three times daily [Bradley 2006].

Method of administration

For oral administration.

Duration of administration

No restriction. If diarrhoea persists or worsens, medical advice should be sought.

Contraindications

None known.

Special warnings and special precautions for use

None required.

Interaction with other medicaments and other forms of interaction

None reported.

E/S/C/O/P MONOGRAPHS

Pregnancy and lactation
In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

Due to the high content of tannins Alchemilla has an astringent effect [Moeck 2007; Blaschek 2009].

In vitro experiments

Antibacterial activity
Various aqueous and ethanolic extracts showed antibacterial activity against *Staphylococcus aureus* and *Bacillus subtilis* [Schimmer 1992].

Astringent activity
The antisecretory activity of a lyophilized hot water extract from *Alchemilla xanthochlora* was examined using isolated rabbit colon. A significant effect could not be demonstrated [Geiger 1994].

The astringency of ellagitannins isolated from *Alchemilla xanthochlora* was determined by haemanalysis with fresh human blood and by their relative affinity to methylene blue. Agrimoniin, pedunculagin and laevigatin F showed the highest activity [Geiger 1991, 1994].

Antioxidant activity
Aqueous and ethanolic extracts of Alchemilla (20 mg powder/10 ml solvent) were tested for their ability to inhibit lipid peroxidation in phosphatidylcholine liposomes by the thiobarbituric acid (TBA) test using butylhydroxytoluene as reference. Inhibition was demonstrated for 3, 10 and 30 µl of the aqueous extract while the ethanolic extract was not active The superoxide anion scavenging activity of the same preparations were tested in the NADH-phenazine methosulfate system. Doses of 10, 30 and 40 µl of the aqueous extract showed a dose-dependent effect [Filipek 1992].

Antioxidant activity was measured by the ABTS assay, and the total polyphenol content was assayed using the Folin-Ciocalteu reagent. An extract from Alchemilla (0.5 g/100 ml water) exhibited higher antioxidant activity expressed as Trolox equivalents (4.79 ± 0.14 mM) than *Ilex paraguariensis* (3.50 ± 0.29 mM) [Kiselova 2006].

A 50 % ethanolic extract demonstrated antioxidant activity by inhibiting H_2O_2-induced cytotoxicity (47.0 ± 3%) and DNA damage (37.2 ± 3.6%) as well as in the DPPH assay (71.8 ± 4.1%) and an Fe^{2+} chelating assay (84.6 ± 3.8%). The same extract decreased bacteriostatic and bactericidal effects of H_2O_2 on *Escherichia coli* and caused an increase in expression of the H_2O_2-inducible gene *katG*, measured by the activity of b-galactosidase in *E. coli* cells [Oktyabrsky 2009].

Anti-inflammatory activity
An aqueous lyophilized extract of Alchemilla did not show inhibitory activity on prostaglandin biosynthesis in bovine seminal vesicle microsomes with ^{14}C-arachidonic acid (reference indometacin). The same extract was tested for its platelet-activating factor (PAF)-induced exocytosis in neutrophils using SAAVNA (0.2 mM) as a substrate and produced an inhibition of 91 ± 4 % [Tunon 1995].

In the hen's egg chorioallantoic membrane (HET-CAM) assay two dry hydroethanolic extracts (lyophilized mother tinctures, not further specified) at a concentration of 500 µg/pellet inhibited membrane irritation by 91 and 100%. The effect was comparable to that of hydrocortisone, phenylbutazone or diclofenac sodium at 50 µg/pellet [Paper 1997].

An Alchemilla fraction consisting of flavone monoglycosides at a concentration of 0.16 mg/ml inhibited 50% of the activity of porcine pancreatic elastase against the substrate N-succinyl-L-alanyl-L-alanine-L-valine-p-nitroanilide (SAAVNA). The inhibitory activity on trypsin and a-chymoptrypsin was less pronounced [Jonadet 1986]. Extracts (25 µg/ml, ethanol 50% V/V) of both flowers and leaves inhibited elastase by 94% [Lamaison 1990].

Antispasmodic activity
A 50% V/V methanolic extract did not show an effect on spontaneous or acetylcholine- or barium chloride-induced contractions of isolated guinea pig ileum at concentrations up to 800 µg/ml [Izzo 1996].

Wound-healing properties
The effects of an Alchemilla fluid extract (3% in glycerol) on cell growth were investigated in Chang Liver and Madin Darby Bovine Kidney (MDBK) epithelial cell lines and in rat aortic myofibroblast cultures. Cell numbers increased with 0.1 - 1% of the extract, attaining 21.3 ± 2.1%, 15.5 ± 2.25% and 10.6 ± 0.6% in MDBK, myofibroblast and Chang liver cells, respectively ($p<0.005$). No morphological changes or cytotoxicity were noted [Shrivastava 2007].

In vivo experiments

Angioprotective effects
An Alchemilla extract rich in flavone monoglycosides was subjected to the capillary permeability test in male rats using the Evans Blue diffusion chamber. At doses of 30 and 60 mg/kg body weight (i.p.), angioprotection significantly ($p<0.001$) increased by 28.0 and 30.1%, respectively. Another fraction consisting of flavone diglycosides showed a non-significant increase [Jonadet 1986].

Haemorheological effects
In 16 spontaneously hypertensive male rats, and 8 female Wistar rats, with arterial hypertension and increased blood viscosity, the effects of an Alchemilla extract (standardised on flavonoids, not further specified) on the structure and function of erythrocytes were examined. The extract was administered intragastrically at a daily dose of 300 mg/kg body weight for 10 days. It had a positive effect on erythrocyte surface morphology as well as on the lipid composition of erythrocyte membranes. Furthermore, the administration of the extract improved erythrocyte deformability [Plotnikov 2006].

Wound-healing properties
The effect of an Alchemilla fluid extract (3% in glycerol) on cell growth was investigated using dorsal skin lesions (8 mm diameter) in adult male rats. The lesions treated topically with

the extract significantly decreased in size by 10.0 ± 0.7% ($p<0.005$) after 2 days of treatment. On day 3 of treatment, the diameter of the lesions was significantly reduced by 15.9 ± 1.1% in glycerine-treated rats compared with distilled water ($p<0.005$), whereas the diameter in verum-treated rats was further reduced by 23.2 ± 1.4% ($p<0.005$) [Shrivastava 2007].

Other effects
The effects of Alchemilla dried leaves and decoction on glucose homoeostasis were evaluated in normal and streptozotocin diabetic mice. The plant material was supplied ad libitum in the diet (6.25% body weight) and additionally as a decoction (1 g/400 ml water) instead of drinking water. After 12 days of administration the animals were challenged with streptozotocin (200 mg/kg b.w. i.p.). Alchemilla did not prevent the development of hyperphagia, polydipsia, body weight loss, hyperglycaemia and hypoinsulinaemia [Swanston-Flatt 1990].

Eight-day-old chicks received i.p. injections of a hydroalcoholic Alchemilla extract (not further specified) 30 minutes before being tested in the presence of two other chicks, or in isolation, for a 3-minute observation period. Sedation, separation-distress and stress-induced analgesia were not changed significantly after application of the extract [Sufka 2001].

The effect of a polyphenol-containing fraction (not further specified) from Alchemilla on the morphofunctional state of the thyroid was examined in rats. The animals were fed with 10 mg/kg b.w. of this extract by gastric tube and then were exposed to cold air (minus 10°C). Enhanced synthesis and an increase in peripheral de-iodated thyroid hormones were observed in both the treatment and the control group. After a subsequent "readaptation phase" at room temperature, the control group showed a compensatory reduction of thyroid function whereas in the treatment group hormone synthesis was stimulated [Borodin 1999].

Clinical data

An open-label study involving 48 otherwise healthy male and female patients (4-44 years of age) examined the effects of a gel containing an Alchemilla fluid extract (3% in glycerol) on common minor oral ulcers. The gel was applied topically three times daily. In 60.4 % of the patients discomfort was relieved and complete healing was achieved within 2 days. In 75 % of the patients, healing was achieved within 3 days, as compared to 15 % without treatment and 40 % with usual treatment (not further specified) [Shrivastava 2006].

Pharmacokinetic properties
No data available.

Preclinical safety data
In the Ames test with *Salmonella typhimurium* strains TA 98 and TA 100, an Alchemilla tincture (1:5, ethanol 70%, species not defined) showed no mutagenicity without activation and weak mutagenicity at a concentration of 40 µl/plate after activation with S9 mix [Schimmer 1988, 1994]. The latter effect is supposed to be caused by quercetin and does not seem to be clinically relevant as Alchemilla preparations have only a low quercetin content [Schimmer 1988].

Hydroethanolic extracts (DER 1:5) from *A. mollis* and *A. alpina* (50% ethanol), and *A. vulgaris* (70% ethanol), were tested for their antimutagenic potency against 2-nitrofluorene as a standard mutagen. The experiments were performed with *Salmonella typhimurium* strains TA 98 and TA 100 without exogenous metabolic system. At doses of 80 and 160 µl/plate all preparations inhibited the induced mutagenicity. The extracts and tincture did not show any significant mutagenicity within the dose range tested [Schimmer 1995].

Clinical safety data
A gel containing an Alchemilla fluid extract (3% in glycerol) used topically on the oral mucosa in an open-label study in 48 patients (4-44 years of age) was well tolerated [Srivastava 2006].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ALLII SATIVI BULBUS

2019

Garlic

DEFINITION

Garlic powder consists of the bulb of *Allium sativum* L., with the outer corneous layer removed, cut, freeze-dried or dried at a temperature not exceeding 65°C and powdered. It contains not less than 0.45 per cent of allicin ($C_6H_{10}OS_2$; M_r 162.3), calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Garlic Powder].

CONSTITUENTS

Carefully dried, powdered material contains about 1 per cent of alliin [(+)-S-allyl-L-cysteine sulphoxide] as the main sulphur-containing amino acid. In the presence of the enzyme alliinase, alliin will be converted to allicin (1 mg of alliin is equivalent to 0.45 mg of allicin).

In turn, allicin is the precursor of various transformation products, including ajoenes, vinyldithiines, oligosulphides and polysulphides, depending on the conditions applied.

Material derived from garlic by steam distillation or extraction in an oily medium contains various allicin transformation products.

Other characteristic, genuine constituents are (+)-S-methyl-L-cysteine sulphoxide, gamma-L-glutamyl peptides, S-allyl-cysteine, ubiquitous amino acids, steroids, triterpenoid saponins, flavonoids, lectins and adenosine [Ackermann 2001; Benavides 2007; Blaschek 2016; Block 1985, Block 1992; Bradley 2016; Koch 1996; Lawson 1993; Sticher 1991; Wang 2015; Xiong 2015].

CLINICAL PARTICULARS

Therapeutic indications

Prophylaxis of atherosclerosis [Bordia 1989; Harenberg 1988; Kiesewetter 1991, 1993a,b; Koch 1996; Koscielny 1999; Orekhov 1995, 1996, 1997; Reuter 1991].

Treatment of elevated blood lipid levels insufficiently controlled by diet [Adler 1997; Auer 1990; Brewitt 1991; Beck 1993; De Santos 1993, 1995; Harenberg 1988; Fatima 2014; Kiesewetter 1993b; Jain 1993; Mader 1990; Orekhov 1996; Reinhard 2009; Ried 2013; Rinneberg 1989; Vorberg 1990; Schilcher 2016; Sobenin 2009b; Walper 1994; Zeng 2012].

Supportive treatment of hypertension [Ashraf 2013; Auer 1990; De Santos 1993, 1995; Holzgartner 1992; Kandziora 1988; Kiesewetter 1993b; Ried 2016; Sobenin 2009a; Vorberg 1990; Wang 2015; Xiong 2015].

Upper respiratory tract infections and catarrhal conditions [Allium BHP 1983; Andrianova 2003; Block 1992; Bradley 1992; Josling 2001; Lissiman 2009, 2014; Rafinsky 1974; Tsai 1985].

Posology and method of administration

Dosage

Prophylaxis of atherosclerosis or treatment of elevated blood lipid levels
Adults: The equivalent of 6-10 mg of alliin (approx. 3-5 mg of allicin) daily, typically contained in one clove of garlic or in 0.5-1.0 g of dried garlic powder [Adler 1997; Auer 1990; Beck 1993; Bordia 1989; Brewitt 1991; De Santos 1993, 1995; Fatima 2014; Harenberg 1988; Holzgartner 1992; Jain 1993; Kandziora 1988; Kiesewetter 1991, 1993a,b; Koch 1996; Koscielny 1999; Mader 1990; Orekhov 1995, 1996, 1997; Reuter 1991; Ried 2013; Rinneberg 1989; Schilcher 2016; Sobenin 2009b; Vorberg 1990; Walper 1994; Zeng 2012].

E/S/C/O/P
MONOGRAPHS

Supportive treatment of hypertension
Adults: The equivalent of 6-10 mg of alliin (approx. 3-5 mg of allicin) daily, typically contained in one clove of garlic or in 0.5-1.0 g of dried garlic powder [Ashraf 2013; Auer 1990; De Santos 1993, 1995; Holzgartner 1992; Kandziora 1988; Kiesewetter 1993b; Schilcher 2016; Sobenin 2009a; Vorberg 1990].

Upper respiratory tract infections
Adults: 2-4 g of dried bulb or 2-4 ml of tincture (1:5, 45% ethanol), three times daily or 180 mg garlic powder per day [Allium BHP 1983; Josling 2001].

Method of administration
For oral administration.

Duration of administration
Long-term treatment is generally advised in the prevention of atherosclerosis and prophylaxis or treatment of peripheral arterial vascular diseases [Kiesewetter 1993b; Koscielny 1999].

Contra-Indications
None known.

Special warnings and special precautions for use
Caution is advised with regard to surgical operations due to some case reports with prolonged or increased bleeding [Burnham 1995; Carden 2002; German 1995; Izzo 2007; Kilic 2014; Shakeel 2010; Woodbury 2016].

Interaction with other medicaments and other forms of interaction
An increased International Normalized Ratio (INR) has been observed in 2 patients on warfarin and in one patient on fluindione who had used garlic products [Sunter 1991; Pathak 2003]. The results of studies with saquinavir and ritonavir in healthy volunteers remain unclear [Piscitelli 2002; Gallicano 2003].

Pregnancy and lactation
There are no objections for use during pregnancy and lactation, because neither long term nutritional experience nor any other important circumstances give reason for concern [Ziaei 2001]. From a controlled trial it is known that major sulphur-containing volatiles from garlic are transmitted to human milk leading to improved drinking habits of the babies [Mennella 1991].

Effects on ability to drive and use machines
None known.

Undesirable effects
In rare cases gastro-intestinal irritation or allergic reactions [Izzo 2007; Mane 2013; Schilcher 2016; Siegers 1989; Vovolis 2010].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties
Garlic exerts antiatherogenic, lipid-lowering, antihypertensive, antiaggregatory, endothelium-relaxing, vasodilatory and antioxidant effects. The effects are primarily due to allicin and its transformation products [Benavides 2007; Bradley 2016; Koch 1996; Ried 2016; Schilcher 2016; Xiong 2015].

In vitro experiments

Antiatherogenic and lipid-lowering effects
Inhibitory effects of extracts and isolated fractions from garlic on cholesterol biosynthesis were observed in chicken hepatocytes and monkey livers. At equivalent doses, both the drug and its lipophilic and hydrophilic fractions caused 50-75% inhibition of cholesterol biosynthesis [Quereshi 1983].

Inhibition of cholesterol biosynthesis by allicin and ajoene was evaluated in cultivated rat hepatocytes and the human liver cell line HepG2. In rat hepatocytes, ajoene inhibited sterol biosynthesis with an IC_{50} of 15 µM; alliin was almost ineffective. In HepG2 cells both allicin and ajoene inhibited sterol biosynthesis with IC_{50} values of 7 and 9 µM, respectively. The inhibition was exerted at the level of HMG-CoA-reductase [Gebhardt 1994].

In a study in primary rat hepatocytes, the water-soluble organosulphur compounds S-allyl cysteine (SAC), S-ethyl cysteine (SEC) and S-propyl cysteine (SPC) inhibited [2-^{14}C]acetate incorporation into cholesterol in a concentration-dependent manner, achieving 42 to 55% maximal inhibition. Other sulphur compounds were less potent. Alliin, S-allyl-N-acetyl cysteine, S-allylsulphonyl alanine and S-methyl cysteine had no effect. Of the lipid-soluble compounds, diallyl disulphide (DADS), diallyl trisulphide (DATS) and dipropyl disulphide (DPDS) reduced cholesterol synthesis by 10 to 25% at low concentrations (≤0.5 mmol/L) and completely inhibited synthesis at high concentrations (≥1.0 mmol/L) [Liu 2000].

Standardized garlic powder (1.3% alliin) inhibited cholesterol biosynthesis in rat hepatocytes with an IC_{50} of 90 µg/ml [Gebhardt 1991, 1993]. In HepG2 cells cholesterol biosynthesis was inhibited by the garlic powder with an IC_{50} of 35 µg/ml [Gebhardt 1993].

The mechanism of action is believed to be an interaction at the molecular level with the phosphorylation cascade of hydroxymethylglutaryl-CoA reductase. Organosulphur compounds containing an allyl disulphide or allyl sulphydryl group are capable of interacting with the thiol group of cysteine and thus forming cysteine derivatives. The antiatherogenic effects of these organosulphur compounds can be attributed to reactions that inhibit HMG-CoA reductase and other lipogenic enzymes [Gebhardt 1994; Mathew 2004; Singh 2006].

A concentration-dependent inhibition of cholesterol synthesis (^{3}H-acetate incorporation in Hep-G2) was exerted by allyl mercaptan, a metabolite of organosulphur compounds. At concentrations between 5 and 100 µg/mL, cholesterol synthesis was inhibited by 20 to 80% in cells (approximately 50% inhibition with 25 µg/mL) and cholesterol secretion into the medium was decreased by 20 to 50% compared with control ($p<0.05$). In cells incubated with 1 mM of oleic acid, allyl mercaptan decreased cholesterol synthesis compared to control ($19.5\pm1.2 \times 10^3$ dots per minute (dpm)/mg protein/4 h vs. $30.0\pm2.6 \times 10^3$ dpm/mg protein/4 h; $p<0.05$) [Xu 1999].

Allicin inhibits the incorporation of ^{14}C-acetate into non-saponifiable neutral lipids at concentrations as low as 10 µM and can be regarded as the most active of the sulphur-containing metabolic products of alliin [Gebhardt 1991].

Inhibition of cholesterol biosynthesis by up to 87% was also observed with petroleum ether, methanol and water extracts of garlic, and a garlic-preparation containing S-allylcysteine [Yeh 1994].

During a 24-hour incubation period garlic powder significantly reduced the level of cholesteryl esters by 26% and free cholesterol by 32% in cells of atherosclerotic plaques of human aorta ($p<0.05$) and inhibited their proliferative activity by 55% at 1 mg/ml [Orekhov 1995].

The antiatherogenic effect of egg-yolk-enriched garlic powder was determined on LDL oxidation and oxidant stress-induced cell injury models. The powder inhibited copper-induced LDL-oxidation in a dose-dependent manner. Pretreatment with the garlic powder significantly suppressed the production of peroxides in HL60 cells and protected endothelial cells from hydrogen peroxide-induced cell injury [Yamaji 2004].

Effects on vascular resistance, fibrinolysis and platelet aggregation
In isolated arterial strips from the dog, garlic at 0.2-200 g powder/litre and ajoene at 10^{-6} to 10^{-3} M hyperpolarised membrane potential by 9.3 mV and 4.2 mV, and reduced muscle tone by up to 0.33 g and 0.16 g, respectively [Siegel 1991,1992].

Similarly, in human coronary artery smooth muscle garlic at concentrations of 0.0002-0.2 g/litre caused dose-dependent hyperpolarisation (2.7 mV at maximum) and relaxation (20% at maximum); half-maximal effects were obtained at 1.15 mg/litre. Allicin and ajoene produced hyperpolarisation of up to 5.1 mV and 4.4 mV, and diminished vascular tone by 24% and 11%, respectively, with half-maximal effects at 6.2×10^{-9} M and 9.9×10^{-9} M [Siegel 1998].

In isolated rat aorta freeze-dried garlic powder dose-dependently inhibited noradrenaline-induced contractions. The EC_{50} values were 5.28 mg/ml in aortas with endothelia and 5.81 mg/ml in aortas without endothelia [Öztürk 1994].

A two-fold activation of endogenous nitric oxide synthesis was observed in isolated thrombocytes obtained from human volunteers after ingestion of a single dose of 4 g of fresh garlic [Das 1995; Sooranna 1996].

Garlic preparations and organosulphur compounds from garlic inhibited collagen-stimulated platelet aggregation in platelet-rich plasma with the following IC_{50} values (µg/ml): an aqueous garlic extract 460, total polar constituents 190, alliin 205, allicin 14.0, total thiosulphinates 13.2, adenosine 0.11, guanosine > 20. In whole blood the strongest effects were exhibited by allicin (IC_{50}:14.0 µg/ml) and adenosine (IC_{50}: 0.11 µg/ml) [Lawson 1992].

Diallyldisulphide (40-200 µg/mL) and diallyltrisulphide (5-100 µg/mL) dose-dependently inhibited platelet aggregation and thromboxane B2 secretion induced by arachidonic acid, adrenaline, collagen and calcium ionophore A23187 [Bordia 1998].

Antioxidant effects
Allicin inhibited lipid peroxidation induced by an ascorbic acid/Fe^{2+} system at a concentration of 0.18 mM [Rekka 1994].

The antioxidant effect of an aqueous garlic extract obtained from 1 mg of garlic powder was comparable to that of 30 nmol of ascorbic acid or 3.6 nmol of α-tocopherol in a chemiluminescence assay [Lewin 1994; Popov 1994]. Radical scavenging activity of preparations containing S-allylcysteine has also been demonstrated in both chemiluminescence and 1,1-diphenyl-2-picrylhydrazyl (DPPH) assays [Imai 1994].

Garlic powder strongly inhibited superoxide production in phorbol ester-activated granulocytes with an IC_{50} of 390 µg/ml, whereas an alliin-enriched but alliinase-inactivated garlic extract did not inhibit superoxide production at concentrations up to 1 g/ml [Siegers 1999].

An aqueous solution of garlic powder (1.3% alliin) reduced radicals generated by the Fenton reaction and liberated by cigarette smoke [Török 1994].

Trichloromethyl and trichloromethylperoxyl free radicals were scavenged by the garlic sulphur components diallyl sulphide, diallyl disulphide and allyl mercaptan. Diallyl disulphide also inhibited CCl_4-promoted liver microsomal lipid peroxidation, and diallyl sulphide was able to react with free radicals formed by UVC-activation of hydrogen peroxide or terbutyl hydroperoxide but not with those produced during UVC activation of terbutyl peroxide. However, all garlic components tested absorbed energy from UVC and became partially destroyed in the process. Allyl mercaptan was able to destroy 4-hydroxynonenal, a key reactive aldehyde produced during lipid peroxidation. Allyl mercaptan and diallyl disulphide were also able to prevent UVC and CCl_4-promoted oxidation of albumin *in vitro* [Fanelli 1998].

Allicin reversed the effect of H_2O_2 on HUVEC death. The activation of PARP-cleavage and Bax expression, and the reduction of pro-caspase-3 levels, were inhibited by allicin [Chen 2014].

Other effects
In the ischaemia-reperfusion model, garlic juice (0.01 mg/mL added to the perfusion solution) significantly ($p<0.05$) increased coronary flow before ischaemia in isolated rat heart. Compared to control, the released lactate dehydrogenase at the first minute, the recovery of rate pressure product, and the left ventricular-developed pressure after 45 minutes, were significantly ($p<0.05$) better in the garlic group [Shackebaei 2010].

An aqueous extract from fresh garlic (100-500 µg/ml) increased the proliferation and improved the morphological characteristics of cultured human fibroblasts (more thin, long and spindle cells instead of large, flat cells) [Svendson 1994].

A similar extract non-competitively and irreversibly inhibited cyclooxygenase activity in rabbit platelets and in lung and vascular aortic tissues with IC_{50} values of 0.35, 1.10 and 0.9 mg, respectively; boiled garlic had only modest effects [Ali 1995].

Anti-aggregatory [Mayeux 1988; Lawson 1992], antibacterial [Sharma 1977; Adetumbi 1983; Gupta 2010], antimycotic [Lutomski 1991; Li 2014], antiviral [Tsai 1985], neuroprotective [Koh 2005; Ishige 2007], anti-parasitic [Kinuthia 2014], and anti-tumour effects [Wargovich 1991; Dorant 1993; Lan 2013; Bagul 2015] of garlic have also been demonstrated.

In vivo experiments

Lipid-lowering and antiatherogenic effects, hypoglycaemic activity
Garlic powder (0.6% allicin) fed to rats for 11 days at 0.25, 0.5 or 1 g/kg b.w. protected against isoprenaline-induced myocardial damage, as shown by histological examination and biochemical analysis [Ciplea 1988].

In the isolated, perfused heart (Langendorff model) from rats which had been given 1% of garlic powder (1.3% alliin) in their diet for 10 weeks, the size of the ischaemic zone (32% vs 41% of total heart tissue; $p<0.05$), incidence of ventricular tachycardia (0% vs 35%; $p<0.05$) and incidence of ventricular fibrillation (50% vs 90%; $p<0.05$) were significantly reduced in comparison with untreated controls [Jacob 1991; Isensee 1993].

A petroleum-ether extract of garlic (corresponding to dried garlic at 1 g/kg b.w.), fed to rats for 5 days in combination with an atherogenic diet, significantly prevented elevation of serum cholesterol and triglyceride levels (92.4 and 93 mg/dl), respectively, compared to 320 and 370 mg/dl in control animals; $p<0.001$), and reduced the incidence and grade of atherosclerotic lesions ($p = 0.0027$) compared to animals fed on the atherogenic diet alone [Lata 1991].

Rabbits were given cholesterol in their diet at 0.5 g/kg b.w. daily for 2 months, then fed for 3 months on a normal diet with or without the addition of fresh garlic at 1 g/kg daily. Compared to rabbits receiving a normal diet over the 3-month period, those given garlic had reduced plaque areas with half as many lesions [Mand 1985].

After de-endothelialisation of the carotid artery, rats were given a diet containing 2% of cholesterol with or without the addition of 5% of garlic powder (1.3% alliin). After 4 weeks, insertion of a balloon catheter revealed only modest inhibition of the growth of neointima in the rats given garlic compared to those given cholesterol alone. However, the garlic inhibited elevation of serum cholesterol by 42% ($p<0.05$) and protected enzymes of the glutathione system, which were strongly impaired under hypercholesterolaemia [Heinle 1994].

In Wistar rats with induced hypercholesterolaemia, and their 1-day-old offspring, pathological changes to myocardial muscle and atherosclerosis of dorsal aorta were observed, affecting the progress of gestation and development of both morphological and skeletal abnormalities. Oral administration of 100 mg fresh garlic/kg b.w. for three weeks prior to onset of gestation as well as throughout the gestation period led to amelioration of histological heart and vessel abnormalities, serum total cholesterol, triglycerides, LDL and creatine kinase activity of both mother and their offspring. Moreover, as compared to those effects seen in animals with experimental hypercholesterolemia, the supplementation reduced the increased incidence of abortions, reduced the decrease in total number of offspring and reduced the marked depletion of body weight; additionally, congenital abnormalities induced by hypercholesterolaemia were not seen in the verum group [El-Sayyad 2010].

In guinea pigs fed a diet enriched with 2.5 and 5% garlic powder for 21 days, significant decreases were found in serum triglycerides (15 and 29%; $p<0.02$), total cholesterol (73 and 78%; $p<0.001$), VLDL (65 and 70%; $p<0.001$) and LDL (69 and 70%; $p<0.001$) when compared to control. HDL remained unchanged [Pourkabir 2010].

The effects of a single dose of an ethanolic garlic extract (250, 300 and 350 mg/kg b.w.) were compared to metformin in normal and alloxan-induced diabetic rabbits. In non-diabetic rabbits a maximum hypoglycaemic response was observed with the highest dose of garlic extract (350 mg/kg b.w.) 4 h after administration, while in diabetic rabbits, blood glucose levels (270.3 ± 0.8 mg/dl) were significantly ($p<0.05$) lowered as compared to control (303.8 ± 1.8 mg/dl). Triglycerides (44.0 ± 0.9 mg/dl) and cholesterol (32.8 ± 0.7 mg/dl) also significantly ($p<0.05$) decreased in non-diabetic rabbits [Sher 2012].

Administration of garlic juice by gavage to STZ-induced diabetic male Wistar rats (1 ml/100 g b.w. per day), resulted in a significant increase in body weight ($p<0.05$), together with a decrease in food intake ($p<0.0001$), and a decrease in glucose-, cholesterol- and TG-levels ($p<0.0001$) [Masjedi 2010].

In alloxan-induced diabetic rabbits, oral administration of a 1% aqueous garlic extract (300 ml three times per day) for 15 days reduced blood glucose (by 51%), cholesterol (35%) and urea (46%) [Rind 2013].

A study investigated the effects of garlic oil and gliclazide on blood glucose levels in alloxan-induced diabetic rats. Garlic oil (1 ml/kg b.w.) or a vehicle were orally administered to groups of rats for 14 days, this was followed by i.p. administration of alloxan for 2 days to induce diabetes, in all but a control group. On day 17, the diabetic rats were given single oral doses of either vehicle, gliclazide (2 ml/kg b.w.), garlic oil (1 ml/kg b.w.) or garlic oil and gliclazide. The gliclazide and combination groups demonstrated a significantly ($p<0.01$) greater mean percentage blood glucose reduction (over a 12 hour period) than the diabetic control group, while the combination had a greater effect than gliclazide alone [Nandyala 2013].

Antihypertensive effects

Garlic powder given for several weeks at 1 g/kg b.w. to spontaneously hypertensive juvenile rats, starting in their fifth week of life, inhibited the development of hypertension and reduced myocardial hypertrophy. In spontaneously hypertensive adult rats (6-7 month of age), garlic lowered blood pressure and myocardial hypertrophy ($p<0.01$) [Jacob 1993].

Garlic powder (1.3% alliin) added at 0.5% to the diet of hypertensive rats significantly ($p<0.02$) prolonged their life span by 22 days (453.2±16.2 days) compared to a control group of of hypertensive rats given the normal diet (434.5±23.5 days). During the course of the study systolic blood pressure was significantly lower in the garlic group ($p<0.01$) [Brändle 1997].

An aqueous garlic extract administered orally to hypertensive two-kidney-one-clip Goldblatt model rats as a single dose at 50 mg/kg b.w. or in repeated daily doses of 50 mg/kg for 2 weeks exerted a significant antihypertensive effect ($p<0.05$) [Al-Qattan 1999].

Other cardiovascular effects

The oral pretreatment of female Wistar albino rats with fresh garlic (125, 250 or 500 mg/kg b.w.) for 30 days, given alone or in combination with 30 mg/kg captopril during the last seven days, showed cardioprotective effects in a modified Langendorff heart model and after isoproterenol-induced myocardial damage [Asdaq 2008a; 2010a]. Given alone, or in combination with 10 mg/kg hydrochlorothiazide, fresh garlic revealed cardioprotective effects against myocardial damage induced by ischaemia-reperfusion and isoproterenol [Asdaq 2009b]. The protective effects on the myocardium after ischaemia-reperfusion injury were also demonstrated histologically and by analysis of heart tissue [Asdaq 2008a]. However, in all studies the highest dose of 500 mg/kg b.w. of fresh garlic did not show cardioprotective effects [Asdaq 2008ab, 2009ab, 2010ab].

In male wistar rats given a high-fat diet for 12 weeks prior to treatment, a garlic extract (1% allicin; 250 or 500 mg/kg b.w. for 28 days) significantly ($p<0.05$) decreased the diet-induced increases in plasma insulin, total cholesterol and oxidative stress levels, and restored heart rate variability, cardiac function and cardiac mitochondrial function [Supakul 2014].

Clotting time was delayed in rats treated orally for 11 days with an ethanolic garlic extract (10 mg/kg b.w./d), and significantly ($p<0.05$) delayed with a combination of the garlic extract at the same dose for 10 days and a single oral dose of warfarin (3 mg/kg b.w.) on day 11, when compared to untreated controls and those given a single dose of warfarin alone. Clot retraction was also shown to be poor in rats given the combination treatment [Musubika 2015].

Antioxidant effects

Pretreatment of female Wistar albino rats with an oral dose of 250 mg/kg b.w. of fresh garlic for 30 days, either alone or combined with 30 mg/kg captopril or 10 mg/kg propranolol during the last seven days of treatment, led to an increase in activities of antioxidant enzymes such as SOD and catalase ($p<0.05$), and retained the activities of lactate dehydrogenase and creatine phosphokinase isoenzyme [Asdaq 2008b, 2010a].

Oral administration of fresh garlic at 125, 250 or 500 mg/kg b.w., given alone for 30 days or in combination with 10 mg/kg b.w. propranolol for the last 7 days of treatment, augmented endogenous antioxidant synthesis at the two lower doses ($p<0.05$), whereas at the highest dose a reduction in the synthesis of SOD and catalase was observed ($p<0.05$) [Asdaq 2010a].

In a study in male Albino rats, administration of fresh garlic (250 mg/kg b.w. p.o.) for 20 days significantly ($p<0.05$) reduced nickel- and chromium-induced increases in the lipid peroxidase (LPO) level and signficantly ($p<0.05$) improved SOD activity [Das 2009].

Administration of garlic oil (10 mg/kg i.p.; n=10) for 8 weeks was compared with a saline control (i.p.; n=10) in alloxan-induced diabetic rats. The garlic oil retarded lipid peroxidation of cellular membranes induced by oxidative stress associated with diabetes. Compared to the saline control, garlic oil significantly ($p<0.05$) decreased the levels of LPO in plasma, erythrocyte lysate and liver tissue homogenate, whereas total thiols were significantly ($p<0.05$) elevated in the plasma and erythrocyte lysate. SOD and GST activity were significantly ($p<0.05$) elevated in erythrocyte lysate and liver homogenate [Saad Abdultawab 2013].

Garlic oil (5 ml/kg b.w.), administered orally 30 minutes before each daily dose of cyclosporine A (25 mg/kg b.w. p.o.) for 3 weeks, attenuated cyclosporine-induced nephrotoxicity in rats. The significant ($p<0.05$) increases in renal dysfunction parameters and levels of serum NO and plasma MDA caused by cyclosporine A were significantly ($p<0.05$) reduced by the co-administration with garlic oil [Abdelsattar 2013].

Garlic has been shown to prevent or reduce biochemical and histological effects of methotrexate (MTX)-induced nephrotoxicity in rats. An aqueous extract (100 g crushed garlic in 100 ml water; squeezed and filtered) administered orally (1 ml/100 g b.w.) for 7 days before and after a single MTX (20 mg/kg b.w.) i.p. injection resulted in decreased urea and creatinine levels, almost normalized change of electrolytes (sodium, potassium, phosphorus, calcium), and increased concentrations of renal antioxidant stress markers such as GSH and catalase as compared to a decrease with MTX alone. Decreased oxidative stress was shown via reduction of malondialdehyde adenosine deaminase and NO levels. MTX-induced alterations in renal morphology (glomerular/tubular) were prevented by garlic [Ahmed 2015].

A study investigated the ameliorative effects of garlic on gentamicin-induced nephrotoxicity in rats. Serum creatinine and blood urea nitrogen levels were significantly increased ($p<0.05$) by the administration of gentamicin (100 mg/kg bw i.p.) for 10 days. When this was followed by 10 days treatment with garlic juice (20 mg/kg b.w. i.p.), these raised levels of serum creatinine and blood urea nitrogen were significantly ($p<0.05$) reduced [Nasri 2014].

In a study investigating cisplatin-induced nephrotoxicity in rats, oral administration of an ethanolic garlic extract (150 or 300 mg/kg b.w.) for 4 days, following a single injection of cisplatin (5 mg/kg b.w.), significantly ($p<0.001$) reduced the cisplatin-induced biochemical changes (increased urea, uric acid, creatinine, blood urea nitrogen) and dose-dependently ($p<0.01$ to $p<0.001$) reduced the cisplatin-induced increase in kidney weight [Anusuya 2013].

Other effects

Post-ischaemic neuroprotective effects of allicin were seen in a rat middle cerebral artery occlusion (MCAO) model. Treatment with allicin (50 mg/kg b.w. i.p.) at 3 and 6 hours, but not 9 hours, after ischaemia induction significantly ($p<0.05$) reduced brain infarct volume, attenuated cerebral oedema and decreased the neurological deficit score when compared to vehicle only treated rats [Lin 2015].

In other studies, antiviral [Nagai 1973; Sohn 2009], antihepatotoxic [Hikino 1986; Nakagawa 1989], antidiabetic [Thomson 2007; Shariatzadeh 2008; Das 2009; Thomson 2013], anti-inflammatory [Sohn 2009; Sahbaz 2014], anti-parasitic [Khalil 2015; Kinuthia 2014], and tumour growth-inhibiting [Wargovich 1991; Dorant 1993] effects of garlic have also been demonstrated.

Pharmacological studies in humans

Rheological and antiatherosclerotic effects

In a randomized, double-blind, placebo-controlled, cross-over study, the influence on cutaneous microcirculation of a single oral dose of 900 mg of garlic powder (1.3% alliin) was evaluated in 10 healthy volunteers. After 5 hours, a significant increase of 55% was observed in erythrocyte velocity in skin capillaries ($p<0.01$) resulting from vasodilatation of precapillary arterioles, which increased in diameter by 8.6% ($p<0.01$) [Jung 1991].

In a 2-week, randomized, double-blind, placebo-controlled, cross-over study involving 10 healthy volunteers, daily ingestion of 600 mg of a standardized garlic powder preparation (1.3% alliin) significantly ($p<0.05$) lowered susceptibility to lipoprotein oxidation by 34% [Phelps 1993].

In an open study involving 101 healthy volunteers (50 – 80 years of age), the effects of 300-900 mg of standardized garlic powder (1.3% alliin) daily on elastic properties of the aorta were investigated for at least 2 years. Compared to the results from an untreated control group, garlic intake attenuated age-related increases in aortic stiffness: significant differences were observed in pulse wave velocity (8.3 vs. 9.8 m/s, $p<0.0001$) and pressure-standardized elastic vascular resistance (0.63 vs. 0.9 $m^2/s^2 \times$ mm Hg, $p<0.0001$); correlation with age was significantly different ($p<0.0001$) for pulse wave velocity (garlic, $r = 0.44$; control, $r = 0.52$) and systolic blood pressure (garlic, $r = 0.48$; control, $r = 0.54$) [Breithaupt-Grögler 1997].

In an open study 8 healthy volunteers took 1 clove of garlic (about 3 g) daily for 16 weeks. Serum thromboxane B2 was significantly ($p<0.001$) reduced from 243 to 24 ng/ml [Ali 1995].

Healthy volunteers ($n = 30$) took 10 g of fresh garlic daily for 2 months. Clotting time increased from 4.15 to 5.02 min ($p<0.001$) and fibrinolytic activity (euglobulin clot lysis time) decreased from 4.17 to 3.26 hours ($p<0.001$). There were no changes in the control group [Gadkari 1991].

In a randomized, double-blind, placebo-controlled, cross-over study, the effect of a single dose of a dried ethyl acetate extract of garlic (55 mg pure garlic oil derived from 9.9 g fresh garlic) on *ex vivo* induced platelet aggregation was investigated in 14 healthy volunteers. In blood collected 4 hours after administration there was a significant ($p<0.05$) reduction of adrenaline-induced platelet aggregation by 12%, but no effect on platelet aggregation induced by collagen or ADP [Wojcikowski 2007].

Incubation of cultured smooth muscle cells for 24 hours with serum from patients with coronary atherosclerosis increased total cell cholesterol by 46.6%. However, incubation with serum taken from the patients 2 hours after ingestion of 300 mg of standardized garlic powder (1.3% alliin) reduced total cell cholesterol to 19.3% [Orekhov 1995].

Lipid-lowering effects
In a randomized, double-blind, placebo-controlled study, significant reductions of up to 30% in fasting and postprandial plasma triglycerides were observed in 24 volunteers after 6 weeks of daily treatment with 900 mg of garlic powder ($p<0.05$ for intergroup differences in fasting plasma triglycerides) [Rotzsch 1992].

In a randomized, double-blind, placebo-controlled study, the effects of taking 600 mg of standardized garlic powder (1.3% alliin) daily were evaluated in 68 volunteers (initial total cholesterol: verum group 222 mg/dl, placebo group 217 mg/dl). After 15 weeks total cholesterol and triglycerides showed a tendency to decrease in the verum group [Saradeth 1994].

In an open study 8 healthy volunteers (initial total cholesterol, 6.1 mmol/L) took 1 clove of garlic (about 3 g) daily for 16 weeks. Total cholesterol decreased by 21% ($p<0.02$) [Ali 1995]. In another open study, total cholesterol decreased by 15.5% ($p<0.001$) in 30 healthy volunteers who took 10 g of garlic daily for 2 months; no change was observed in an untreated control group [Gadkari 1991].

In a 12-week randomized, double-blind, placebo-controlled trial, 62 healthy volunteers received 920 mg garlic per day (corresponding to 10.8 mg alliin) or placebo. No significant differences in serum lipids (total cholesterol, LDL, HDL) were found. There was a decrease (12 %; p= 0.07) in triacylglycerol concentration [Turner 2004].

In a double-blind, randomized, placebo-controlled, cross-over study in 100 healthy volunteers, 500 mg of garlic (details and daily dosage not given) administered for up to 9 months showed no effect on blood lipid levels [Tanamai 2004].

In a randomized, placebo-controlled study involving healthy volunteers, administration of garlic oil (8.2 mg allyl sulphide daily; n=19) or garlic powder (7.8 mg allicin daily; n=20) for 11 weeks did not lead to changes in plasma lipid parameters when compared to placebo (n=21). A gender-specific analysis revealed that garlic oil exerted significant increases in HDL-cholesterol ($p<0.004$) and reductions in the ratio of total cholesterol:HDL-cholesterol ($p<0.003$) in women [Zhang 2001].

Clinical studies

Antihypertensive effects

Systematic reviews/meta-analyses
In an early meta-analysis of 8 studies, the effect of garlic on blood pressure was evaluated. The overall pooled mean difference in the absolute change from baseline to final measurement of systolic blood pressure was greater (7.7 mmHg) in subjects who were treated with garlic than those treated with placebo; the effect on diastolic blood pressure (5 mmHg) was smaller. The results suggested that garlic powder may have some clinical benefit in mild hypertension [Silagy 1994a].

A systematic review of 45 randomized trials assessing the effects of garlic on several cardiovascular-related factors revealed that inconsistent effects on blood pressure were reported in the studies. The authors noted that conclusions regarding clinical significance were limited by the low quality and short duration of many trials and by the unpredictable release and inadequate definition of active constituents in the study preparations [Ackermann 2001].

A meta-analysis of 10 randomized, controlled trials studying the effect of garlic on blood pressure in both normotensive and hypertensive subjects, suggested that garlic is associated with blood pressure reductions only in patients with an elevated systolic blood pressure [Reinhart 2008].

A systematic review suggested that the contradictory results described in previous meta-analyses assessing the effect of garlic on blood pressure can be attributed to methodological deficiencies. The methodological quality of the selected studies (32 in all, 13 evaluated in previous meta-analyses) was considered to be poor. Only four trials had adequate allocation concealment, no trial reported an intention-to-treat analysis, and the evaluators were blinded in only three of the trials. Futhermore, half of the studies did not report any information regarding the details of blood pressure measurement. All trials fulfilling a predefined cut-off point for quality criteria (methodological and blood pressure measurement) were conducted in normotensive subjects and none of these found garlic to lower blood pressure. For these reasons, the authors conclude that the effect of garlic on blood pressure cannot be ascertained [Simons 2009].

A meta-analysis of 17 randomized controlled trials showed that garlic was superior to controls (placebo in most trials) in reducing blood pressure (BP), especially in hypertensive patients. Pooled analysis showed that garlic intake caused a 3.75-mm Hg reduction (95% CI, -5.04 to -2.45, $p<0.001$) in systolic BP and a 3.39-mm Hg reduction (95% CI, -4.14 to -2.65, $p<0.001$) in diastolic BP compared with controls. Meta-analysis of subgroups showed a significant reduction in systolic BP in hypertensive (-4.4 mm Hg; 95% CI, -7.37 to -1.42, p=0.004) but not normotensive patients. Significant diastolic BP reduction (-2.68 mm Hg, 95% CI, -4.93 to -0.42, p=0.02) was shown in hypertensive patients after sensitivity analysis [Wang 2015].

In a systematic review and meta-analysis of seven randomized, placebo-controlled trials comparing garlic with placebo in hypertensive patients, garlic had a significant lowering effect on both systolic BP (weighted mean difference (WMD): -6.71 mmHg; 95% CI: -12.44 to -0.99; p=0.02) and diastolic BP (WMD: -4.79 mmHg; 95% CI: -6.60 to -2.99; $p<0.00001$) [Xiong 2015].

A meta-analysis of 20 randomized, controlled trials, including 970 participants, found a mean decrease in systolic blood pressure (SBP) of 5.1 ± 2.2 mm Hg ($p<0.001$) and in diastolic blood pressure (DBP) of 2.5 ± 1.6 mm Hg ($p<0.002$) when compared with placebo. A subgroup analysis of hypertensive subjects (SBP/DBP ≥140/90 mm Hg at baseline) revealed a greater significant reduction in SBP of 8.7 ± 2.2 mm Hg ($p<0.001$) and in DBP of 6.1 ± 1.3 mm Hg ($p<0.001$) [Ried 2016].

Clinical trials
In a randomized, double-blind, placebo-controlled study, 52 patients with hypercholesterolaemia and mild systolic hypertension were treated with 900 mg of standardized garlic powder (1.3% alliin) daily for 6 months. Systolic and diastolic blood pressure (initial values: 145 and 90 mmHg) were reduced by 17% ($p<0.001$) and 10% ($p<0.01$), respectively, in the verum group, but remained unchanged in the placebo group ($p<0.001$ for intergroup comparison) [De Santos 1993].

In a randomized study the effects of daily treatment with 600 mg of standardized garlic powder (1.3% alliin, equivalent to 0.6% allicin) were compared to those of 1.98 mg of garlic oil in 80 patients with mild hypercholesterolaemia and mild hypertension. By the end of 4 months of treatment, initial systolic and diastolic blood pressures of 151 and 96 mmHg had decreased by 19 and 17% respectively (both $p<0.001$) in the garlic powder group, whereas no effects were observed in

the garlic oil group (p<0.001 for intergroup comparison) [De Santos 1995].

In a randomized, double-blind, placebo-controlled study the effects of 600 mg of standardized garlic powder (1.3% alliin) daily for 12 weeks were evaluated in 47 patients with mild hypertension. In the verum group, initial supine and standing diastolic blood pressures of 102 and 101 mmHg decreased by 13% and 11% respectively (p<0.05), while in the placebo group initial values of 97 and 94 mmHg decreased by 4% and 0.5% respectively (not significant). Initial systolic blood pressures of 171 and 161 mmHg in the verum and placebo groups respectively decreased by 12% (p<0.05) and 6% (not significant). Intergroup comparisons were not reported [Auer 1990].

In a 12-week randomized, reference-controlled study involving 98 normotensive patients with primary hyperlipoproteinaemia, the effects of daily administration of 900 mg of garlic powder (1.3% alliin) or 600 mg of bezafibrate were compared. Systolic blood pressures of 143.4 mmHg in the garlic group and 140.6 mmHg in the bezafibrate group were reduced by 5.5% and 2%, respectively (p<0.05 in favour of garlic). Initial diastolic blood pressures of 82.8 and 82.4 mmHg, respectively decreased by 5% in both groups [Holzgartner 1992].

In a randomized, double-blind, placebo-controlled study 40 patients with moderate hypertension (systolic blood pressure, 178 mmHg; diastolic, 100 mmHg) undergoing concomitant diuretic treatment with triamterene and hydrochlorothiazide received 600 mg of standardized garlic powder (1.3% alliin) or placebo daily. After 12 weeks systolic blood pressure had decreased by 9% in the verum group compared to 3% in the placebo group (p<0.001), while diastolic pressure had decreased by 15% in the verum group compared to 9% in the placebo group (p<0.001) [Kandziora 1988].

In a randomized, double-blind study 40 patients with hypercholesterolaemia and slightly elevated blood pressures received 900 mg of standardized garlic powder (1.3% alliin) or placebo daily. After 16 weeks, supine systolic and diastolic blood pressures were significantly lowered in the verum group (p<0.001 and p<0.05, respectively) compared to the placebo group [Vorberg 1990].

In a randomized, double-blind study 80 normotensive patients with peripheral arterial occlusive disease received 800 mg of standardized garlic powder (1.3% alliin) or placebo daily. After 12 weeks of therapy the initial diastolic blood pressure of 85 mmHg in the verum group had decreased by 3.5% (p<0.04), while that in the placebo group (initially 83 mmHg) remained unchanged [Kiesewetter 1993b].

In a randomized, double-blind study 42 patients with mild hypercholesterolaemia were treated with 900 mg of standardized garlic powder (1.3% alliin) or placebo daily for 12 weeks. At the end of the study systolic and diastolic blood pressures remained unchanged [Jain 1993].

In an open study, 20 patients with mild essential hypertension received two 250 mg garlic oil capsules (2.5% w/v, not clearly specified) daily for 8 weeks. A significant (p<0.05) decline in mean systolic (148±12 to 140±16 mmHg) and diastolic (94±15 to 85±23 mmHg) blood pressure was observed compared to baseline. Furthermore, significant (p<0.05) reductions in 8-hydroxy-2´-deoxyguanosine and 8-iso-prostaglandin F2α (biomarkers of oxidative stress), plasma oxidized LDL, NO levels and lipid peroxidation were observed, as well as a significant (p<0.05) increase in vitamin A, C and E levels and total antioxidant status, when compared to baseline levels [Dhawan 2004, 2005].

An acute dose study involving 75 patients with hypertension showed no significant effects on blood pressure in any of the three patient groups: placebo; 1 clove of garlic (slightly chewed and swallowed), or 12 tablets of garlic (slightly chewed and swallowed; 2.4 mg allicin) for up to an hour after consumption [Capraz 2007].

In an open study involving 50 type 2 diabetic patients with hyperlipidaemia (total cholesterol ≥220 mg/dl), administration of 900 mg garlic powder daily for 6 weeks resulted in a reduction of systolic blood pressure (p<0.03) [Parastouei 2006].

In an open study, 70 hypertensive patients received an oily garlic preparation (1.6 g garlic macerate 1:1; 1.6 mg allicin derivatives) in addition to standard antihypertensive treatment for 30 days. There were no significant changes in systolic and diastolic blood pressure. A gender-specific analysis revealed a trend for better effects in women as compared to men [Duda 2008].

A placebo-controlled study involving 100 women in their third trimester of pregnancy was conducted to evaluate whether garlic (800 mg powdered garlic with 1 mg allicin daily for 8 weeks) could prevent pre-eclampsia. No difference between the garlic and control groups in the relative risk of gestational hypertension or pre-eclampsia was observed [Ziaei 2001].

In a double-blind, placebo-controlled trial, patients with mild or moderate hypertension (systolic blood pressure 150-160 mmHg, diastolic blood pressure 90-115 mmHg) received 600 mg garlic powder daily (n=30) or placebo (n=20) for 8 weeks after an 8 week placebo-run-in phase. As compared to the baseline values (after the placebo run-in-phase), garlic significantly reduced systolic and diastolic blood pressures by 7.0 mmHg and 3.8 mmHg respectively (p<0.001). There was also a significant (p<0.001) difference compared to the placebo group [Sobenin 2009a].

In a single-blind, placebo controlled, multicentre study, patients with stage 1 essential hypertension (30 per group) received garlic tablets (not further specified) for a period of 24 weeks at daily doses of 300, 600, 900, 1200 or 1500 mg, atenolol (100 mg) or placebo. Garlic demonstrated dose- and duration-dependent significant (p<0.05) reductions in systolic and diastolic blood pressure when compared to placebo; the activity was comparable with atenolol at doses of 600 mg and above at 24 weeks [Ashraf 2013].

Rheological and antiatherosclerotic effects

Systematic reviews/meta-analyses

A systematic review of 45 randomized trials summarized the effects of garlic on several cardiovascular-related factors. The relevant trials reported modest but significant reductions in platelet aggregation with garlic treatment (without additional anti-platelet medication) compared with placebo. The authors noted that conclusions regarding clinical significance were limited by the low quality and short duration of many trials and by the unpredictable release and inadequate definition of active constituents in the study preparations [Ackermann 2001].

Clinical trials

In a randomized, double-blind study, 60 young patients (average age 24 years) with constantly elevated spontaneous platelet aggregation and at increased risk of ischaemic attack were treated with 800 mg of standardized garlic powder (1.3% alliin) or placebo daily for 4 weeks. In the garlic group the ratio of

circulating platelet aggregation decreased by 10.3% (p<0.01; placebo group unchanged) and spontaneous platelet aggregation decreased by 56.3% (p<0.01; placebo group unchanged) [Kiesewetter 1991, 1993a].

In a double-blind study 80 patients with peripheral arterial occlusive disease received 800 mg of standardized garlic powder (1.3% alliin) or placebo daily for 12 weeks. In the garlic group plasma viscosity decreased by 3.6% (p<0.0013) and spontaneous platelet aggregation dropped by 59% (p<0.01) while these parameters were unchanged in the placebo group [Kiesewetter 1993b].

In a randomized, double-blind study, 23 patients with coronary arterial disease received 900 mg of standardized garlic powder (1.3% alliin) or placebo daily for 3 weeks. The cholesterol content per mg of cell protein decreased from 40 to 28 µg, the LDL oxidation lag-time was prolonged from 133 to 176 min and the LDL-sialic acid content increased from 22 to 33 nmol/mg lipoprotein. In the control group these parameters remained unchanged [Orekhov 1996].

In an open study 20 patients with hypercholesterolaemia were treated daily for 4 weeks with 600 mg of dried garlic. Fibrinogen decreased by 10% (p<0.01) and fibrinopeptide A by 45% (p<0.01); streptokinase-activated plasminogen increased by 15% (p<0.01) and fibrinopeptide Bβ 15-42 by about 42% (p<0.01) [Harenberg 1988].

Lipid-lowering effects

Systematic reviews/meta-analyses

The effect of garlic on total serum cholesterol has been assessed in 9 meta-analyses [Warshafsky 1993; Silagy 1994b; Neil 1996; Stevinson 2000; Ackermann 2001; Reinhart 2009; Khoo 2009; Zeng 2012; Ried 2013]. In most of them it was concluded that the available data showed garlic to be superior to placebo in reducing total cholesterol; however, only a modest effect was indicated from one meta-analysis [Stevinson 2000] and no benefit on serum cholesterol was found in one meta-analysis [Khoo 2009].

A systematic review of 45 randomized trials summarized the effects of garlic on several cardiovascular risk-related factors. When compared with placebo, garlic preparations led to small reductions in the total cholesterol level at 1 month (range of average pooled reductions, 0.03-0.45 mmol/l [1.2-17.3 mg/dL]) and at 3 months (range of average pooled reductions 0.32-0.66 mmol/l [12.4-25.4 mg/dL]), but not at 6 months. Changes in the levels of LDL and triglycerides paralleled those of total cholesterol, while there were no significant changes in HDL levels observed. The authors noted that conclusions regarding clinical significance were limited by the low quality and short duration of many trials and by the unpredictable release and inadequate definition of active constituents in the study preparations [Ackermann 2001].

A meta-analysis of 13 trials (11-24 weeks in duration) including 1056 healthy or hypercholesterolaemic subjects showed that administration of garlic did not have any significant effects on lipid profile compared with placebo [Khoo 2009].

A meta-analysis of 29 trials studying garlic preparations revealed a significant reduction of total cholesterol (by 0.19 mmol/l (95% CI -0.33, -0.06); = 7.35 mg/dl) and triglycerides (by 0.11 mmol/l (95% CI -0.19, -0.03); = 9.7 mg/dl) as compared to placebo, but exhibited no significant effects on LDL or HDL [Reinhart 2009].

A meta-analysis of 26 randomized, double-blind, placebo-controlled trials concluded that garlic was superior to placebo in reducing serum total cholesterol (TC) and triglyceride levels. Compared with placebo, TC levels were significantly (p=0.001) reduced by 0.28 mmol/L (95% CI, -0.45, -0.11) and triglyceride level significantly (p<0.001) reduced by 0.13 mmol/L (95% CI, -0.20, -0.06) in the garlic group. The effects of garlic were more pronounced with long-term intervention and in subjects with higher baseline cholesterol levels. Garlic powder was more effective in reducing serum cholesterol levels, while garlic oil was more effective in lowering serum triglyceride levels. However, garlic did not influence other lipid parameters, including LDL, HDL, apolipoprotein B and TC/HDL ratio [Zeng 2012].

A meta-analysis of 39 trials investigating the effect of garlic preparations on serum lipids revealed that garlic reduced total serum cholesterol compared with placebo by 15.25 mg/dL (95% CI, -20.72, -9.78; p<0.0001). The effect was stronger in individuals with elevated total cholesterol levels (>200 mg/dL) when garlic was used for more than 2 months (-17.20 mg/dL; 95% CI, -23.10, -11.30; p<0.0001). Similar results were also seen for LDL, while HDL levels improved only slightly, and triglycerides were not influenced significantly [Ried 2013].

Comparative studies

The lipid-lowering effect of 900 mg of garlic powder (standardized to 1.3% alliin) daily (G) was compared to that of 600 mg of bezafibrate daily (B) in 98 patients with hyperlipoproteinaemia. After 12 weeks of treatment, both groups showed significant reductions in total cholesterol (G 25%, B 27%; p<0.001) and LDL (G 32%, B 33%; p<0.001) as well as an increase in HDL (G 51%, B 58%; p<0.001). No significant differences were found between the two groups [Holzgartner 1992].

In a randomized study the effects of daily treatment with 600 mg of standardized garlic powder (1.3% alliin) or 1.98 mg of garlic oil were compared in 80 patients with mild hypercholesterolaemia. After 4 months of treatment total cholesterol had decreased by 11% in the garlic powder group (p<0.001) and by 3% in the garlic oil group. LDL was reduced by 16% in the garlic powder group (p<0.001) and by 1% in the garlic oil group (intergroup comparison: total cholesterol, not significant; LDL, p<0.001) [De Santos 1995].

In a randomized study involving 20 hyperlipidaemic patients (serum cholesterol and triglyceride levels > 200 and 280 mg/dl respectively), the effects of garlic powder compared with clofibrate were investigated. Each patient took garlic at a dose of 900 mg (equivalent to 2.7 g of fresh garlic and 11.7 mg alliin) or 100 mg clofibrate daily for 8 weeks. After 4 and 8 weeks, total cholesterol was reduced with garlic by 9.8 and 17.5% and with clofibrate by 3.0 and 7.2%, respectively. Triglyceride levels were reduced by 34.8 and 43.7% with garlic and by 21.3 and 25.5% with clofibrate. Garlic demonstrated a significantly (p<0.01) greater effect than the clofibrate [Nouri 2008].

Placebo-controlled studies

A placebo-controlled, randomized study evaluated the effects of fresh or powdered garlic on plasma lipid concentrations in adults with moderate hypercholesterolaemia (LDL 3.36-4.91 mmol/L). The daily dosages of 4 g fresh garlic (n=49), 1.4 g powdered garlic (n=47) or placebo (n=48) were administered 6 days a week for 6 months. There were no statistically significant effects on the plasma lipids [Gardner 2007].

In a double-blind, randomized, placebo-controlled trial, the effects of a daily dose of 2.1 g garlic powder on biomarkers for inflammation, endothelial function and lipid metabolism were studied in 90 overweight subjects with cardiovascular risk factors (BMI >24.5 kg/m², >10 cigarettes/d, 40-75 years of age), in comparison to atorvastatin. The subjects were randomly

assigned to 3 parallel treatment groups: garlic powder (2.1 g/d), atorvastatin (40 mg/d), or placebo. In contrast to atorvastatin the garlic preparation had no effect on the variables as compared to placebo [Van 2006].

In a randomized, double-blind, placebo-controlled study the effect of standardized garlic powder tablets (1.3% alliin) was investigated in 261 patients with hyperlipidaemia (initial cholesterol: verum 266, placebo 262 mg/dl). The patients received 800 mg of garlic powder or placebo daily for 16 weeks. In the garlic group mean serum total cholesterol levels dropped by 12% ($p<0.001$) and triglyceride values by 17% ($p<0.001$); both results were significant ($p<0.001$) compared to placebo treatment. A subgroup analysis revealed better results in patients with increased initial lipid levels [Mader 1990].

In a randomized, double-blind, placebo-controlled study, 42 patients with mild hypercholesterolaemia (serum total cholesterol: verum 262, placebo 276 mg/dl) were treated with 900 mg of standardized garlic powder (1.3% alliin) or placebo daily for 12 weeks. In the garlic group serum total cholesterol decreased by 6% ($p<0.01$ vs. baseline and placebo) compared to 1% in the placebo group and LDL by 11% ($p<0.05$ vs. baseline and placebo) compared to 3% in the placebo group [Jain 1993].

In a randomized, double-blind, placebo-controlled study, 46 patients with mild hypercholesterolaemia (6.5 mmol/dl) were assigned to one of four daily treatments: group I, 900 mg of standardized garlic powder (1.3% alliin); group II, 12 g of fish oil; group III, 12 g of fish oil + 900 mg of standardized garlic powder; group IV, placebo. After 3 weeks of treatment the changes in serum total cholesterol and LDL, respectively, were: group I, -11.5% and -14.2%; group II, 0% and + 8.8%; group III, -12.2% and -9.5%; group IV, +4.5% and -1.4%. The differences in groups I and III were significant ($p<0.01$) compared to those in groups II and IV [Adler 1997].

In a randomized, double-blind study 52 patients with hypercholesterolaemia were treated with 900 mg of standardized garlic powder (1.3% alliin) or placebo daily for 6 months. Baseline serum total cholesterol levels were 6.92 mmol/litre in the garlic group and 7.05 mmol/litre in the placebo group. Serum total cholesterol and LDL, respectively, decreased by 9% ($p<0.01$ vs. baseline, $p<0.05$ vs. placebo) and 10% ($p<0.05$ vs. baseline) in the verum group and by 4% and 6% in the placebo group [De Santos 1993].

In a randomized, double-blind study 40 patients with moderate hypertension (blood pressure 178/100 mmHg) and hypercholesterolaemia (280 mg/dl) received 600 mg of standardized garlic powder (1.3% alliin) or placebo daily. After 12 weeks serum total cholesterol had decreased by 10% ($p<0.05$) and triglycerides by 8% ($p<0.05$); no changes were observed in the placebo group [Kandziora 1988].

In a randomized, double-blind study, 40 patients with hypercholesterolaemia received 900 mg of standardized garlic powder (1.3% alliin) or placebo daily. After 16 weeks of treatment, serum total cholesterol had decreased by 21% in the verum group and 3% in the placebo group (intergroup difference $p<0.001$). Serum triglycerides decreased by 24% in the verum group and 3% in the placebo group ($p<0.05$) [Vorberg 1990].

In a randomized, double-blind study 23 patients with coronary artery disease (determined by selective coronary angiography) received 900 mg of standardized garlic powder (1.3% alliin) or placebo daily. Initial serum total cholesterol levels were 218 mg/dl in the verum group and 219 mg/dl in the placebo group. After 3 weeks of treatment HDL had increased by 16% in the verum group ($p<0.05$); total cholesterol and triglycerides remained unchanged [Orekhov 1996].

In a randomized, double-blind study, 80 patients with peripheral arterial occlusive disease (determined by angiography) were assigned to treatment with 800 mg of standardized garlic powder (1.3% alliin) or placebo daily for 12 weeks. Initial serum total cholesterol levels of 266.5 and 264.4 mg/dl in the verum and placebo groups, respectively, decreased by 12% and 4% (intergroup comparison $p<0.011$) [Kiesewetter 1993b].

In a randomized, double-blind study the effects of 600 mg of standardized garlic powder (1.3% alliin) or placebo daily for 12 weeks were compared in 47 patients with mild hypertension. The baseline serum total cholesterol level of 268 mg/dl decreased by 14% in the garlic group ($p<0.05$ vs. baseline) and 6% in the placebo group (not significant). Serum triglycerides decreased by 18% in the garlic group ($p<0.05$) and 6% in the placebo group (not significant) [Auer 1990].

In a single-blind, placebo-controlled trial, administration of garlic tablets (not further specified) at 900 mg per day for 3 months to hyperlipidaemic patients (n=55) significantly ($p<0.001$) reduced total cholesterol by 9.37%, triglycerides by 1.30%, LDL by 17.59% and increased HDL-cholesterol by 5.54%, as compared to baseline values. The placebo hyperlipidaemic patient group (n=51) did not demonstrate significant changes in any of the tested parameters [Fatima 2014].

In a randomized, double-blind, placebo-controlled study 51 patients with coronary heart disease were treated with 300 mg time-released garlic powder tablets or placebo daily for 12 months. There were significant decreases in total cholesterol (-12.4 %; $p=0.004$) and LDL (-16.3%; $p=0.001$) as compared to baseline. The cholesterol lowering effects were significantly ($p=0.038$) greater for garlic than placebo. The most significant effects were observed in men [Sobenin 2009b].

Placebo-controlled studies in combination with defined diet
In a single-blind, randomized, placebo-controlled study the effects of garlic were studied in hyperlipidaemic patients (total cholesterol ≥200 mg/dl and/or LDL ≥100 mg/dl). Patients were given a garlic powder tablet (400 mg garlic,1 mg allicin; n=50) or placebo (n=50) twice daily for 6 weeks. All patients were put on the NCEP step II diet (not more than 7% of calories from saturated fat, not more than 30% of calories from total fat and less than 200 mg of cholesterol per day). Garlic had significant ($p<0.001$) effects on total cholesterol (12.1% reduction), LDL (17.3% reduction) and HDL (15.7 % increase), but no significant effect on triglycerides [Kojuri 2007].

After 8 weeks on an NCEP Step I diet (8-10% of calories from saturated fat, not more than 30% of calories from total fat and less than 300 mg of cholesterol per day), the effects of 900 mg of standardized garlic powder (1.3% alliin) or placebo daily for 12 weeks were compared in a randomized, double-blind study in 50 patients with hyperlipidaemia (initial serum total cholesterol: garlic group 274 mg/dl, placebo group 250 mg/dl). The diet was maintained during the course of study. There were no significant changes to lipid levels in either group and no intergroup differences were observed for serum total cholesterol or LDL [Isaacson 1998].

Over 1200 patients with hypercholesterolaemia embarked on an NCEP Step I diet. After 6 weeks, 115 patients who had not responded to the diet (serum total cholesterol 6.0-8.0 mmol/dL) maintained the diet and were enrolled in a randomized, double-blind study, assigned to 900 mg of standardized garlic powder (1.3% alliin) or placebo daily for 6 months. The baseline

serum total cholesterol levels were 6.96 and 6.99 mmol/litre in the garlic and placebo groups respectively. At the end of this study there were no intra- nor inter-group differences in lipid parameters [Neil 1996].

In a randomized, double-blind, crossover study (2 × 12 weeks, with a wash-out period of 4 weeks) 30 patients with hypercholesterolaemia (serum total cholesterol 6.72 mmol/litre) were treated with 900 mg of standardized garlic powder (1.3% alliin) or placebo daily. All patients maintained an NCEP Step I diet during the study. No effects on serum lipids were observed [Simons 1995].

After following an NCEP Step II diet for 6 months, 30 children with primary familial hypercholesterolaemia participated in a randomized, double-blind study and were assigned to 900 mg of standardized garlic powder (1.3% alliin) or placebo daily for 8 weeks. Baseline serum total cholesterol levels were 6.66 and 7.06 mmol/litre in the garlic and placebo groups respectively. No effects on serum lipid levels were observed except for a 10% increase in apolipoprotein A-I in the garlic group ($p = 0.03$) [McCrindle 1998].

In a randomized, double-blind study, 35 renal transplant patients with serum total cholesterol levels of 290 mg/dl followed an NCEP Step I diet and were also treated with 1.36 g of an undefined garlic preparation (equivalent to 4 mg of allicin daily) or placebo daily for 12 weeks. After 6 and 12 weeks of treatment serum total cholesterol decreased by 5% in the garlic group ($p<0.05$) while serum levels in the placebo group remained unchanged. Serum triglycerides increased by 7.5% (not significant) and HDL decreased by 5% (not significant) in the garlic group, while in the placebo group these parameters changed by +17.3% ($p<0.05$) and -6% ($p<0.05$) respectively [Lash 1998].

After following an NCEP Step I diet for at least 2 weeks (and maintaining it during the course of study), 50 patients with moderate hypercholesterolaemia (LDL subclass pattern A or B; mean serum LDL 166 mg/dl) participated in a randomized, double-blind study, taking 900 mg of standardized garlic powder (1.3% alliin) or placebo daily for 3 months. At the end of the study no significant changes were observed in lipid parameters [Superko 2000].

In a 16 week double-blind, placebo-controlled study in 33 patients with primary hypercholesterolaemia (LDL 130-190 mg/dl after at least 4 weeks of generalized dietary modification), the effects of garlic powder (22.4 mg alliin corresponding to approx. 10 mg allicin daily) on lipid profile and various mental parameters (depression, impulsiveness, hostility and temperament) were compared with placebo. Both groups received individual dietary counseling (NCEP Step I diet). No significant effects on lipid and mental parameters were observed within or between the groups [Peleg 2003].

In a randomized, double-blind, placebo-controlled trial 136 hypercholesterolaemic patients (cholesterol concentrations ≥ 5.2 mmol/L resp. >200 mg/dl) received garlic (333 mg garlic preparation equivalent to 7 g fresh garlic, standardized to 5.6 mg allicin; n=70) or placebo (n=66) for 12 weeks. All patients were given advice to follow NCEP Step I diet for 4 weeks prior to randomization and during the study. There were no statistically significant changes in serum lipid parameters or in plasma glucose, liver or renal functions [Satitvipawee 2003].

Open studies

Patients with hyperlipoproteinaemia type IV (n = 5) and hypercholesterolaemia (n = 15) were treated daily for 4 weeks with 600 mg of garlic powder. The initial mean serum total cholesterol of 278 mg/dl decreased by 7.2% ($p<0.01$) [Harenberg 1988].

Patients with hyperlipidaemia (n = 44; serum total cholesterol 298 mg/dl, triglycerides > 200 mg/dl) were treated with 1.2 g of standardized garlic powder (1.3% alliin) for 18 weeks. Serum total cholesterol decreased by 11.3% ($p<0.001$), LDL by 15.7% ($p = 0.003$) and triglycerides by 13%; HDL increased by 19.9% [Rinneberg 1989].

Patients with hyperlipidaemia (n=1024; initial serum total cholesterol 297 mg/dl) took 600-900 mg of standardized garlic powder (corresponding to 3-6 mg of allicin) for 16 weeks. Serum total cholesterol decreased by 15.8%, LDL by 13.3% and triglycerides by 13.7%; HDL increased by 14.3% [Brewitt 1991].

Patients with hyperlipidaemia (n = 1873; serum total cholesterol > 200 mg/dl or elevated triglycerides) were treated with 900 mg of standardized garlic powder (1.3% alliin) for 16 weeks. Initial average serum total cholesterol of 290 mg/dl decreased by 16.4% ($p<0.0001$), LDL by 15.1% ($p<0.0001$) and triglycerides by 21% ($p<0.0001$); HDL increased by 9.4% ($p<0.0001$) [Beck 1993].

Patients with hypercholesterolaemia (n=917; serum total cholesterol 262 mg/dl), following a cholesterol and fat-reduced diet, were treated with 600 mg of standardized garlic powder (1.3% alliin) daily for 6-8 weeks. Serum total cholesterol decreased by 2.3% ($p<0.01$) [Walper 1994].

In type 2 diabetic patients with hyperlipidaemia (n=50; total cholesterol ≥ 220 mg/dL), the administration of 900 mg garlic powder daily for 6 weeks resulted in a significant reduction of total cholesterol ($p<0.01$) and LDL ($p<0.001$), and a significant increase in HDL ($p<0.02$). There were no significant effects on diastolic blood pressure, fasting blood sugar, serum triglycerides and HbA1c [Parastouei 2006].

Hypertensive patients (n=70) received 6 capsules of an oily garlic preparation daily, in addition to standard antihypertensive medications, for 30 days. Each capsule contained 270 mg garlic macerate in rapeseed oil (1:1) with 0.27 mg of allicin derivatives standardized for allicin. Total cholesterol and LDL were significantly ($p<0.05$) reduced, while HDL increased nonsignificantly. There was also a slight increase of 7 to 10% in the proportion of patients with normal total serum cholesterol levels at the end of the study [Duda 2008].

Prophylaxis of atherosclerosis

Patients homogenous in all demographic data except age (verum > placebo, $p<0.001$), with advanced atherosclerotic plaques (measured by ultrasound in the carotid bifurcation and/or femoral arteries) and at least one risk factor (high systolic blood pressure, hypercholesterolaemia, diabetes mellitus, smoking), participated in a randomized, double-blind, placebo-controlled study. They were assigned to treatment with 900 mg of standardized garlic powder (1.3% alliin; n = 140) or placebo (n = 140) daily for 48 months; 152 patients (61 in the garlic group and 91 in the placebo group) completed the study; 38% of patients in the verum group dropped out because of annoyance with odour. In the remaining patients plaque volume decreased by 2.6% in the verum group and increased by 15.6% in the placebo group. The strongest effects (in both directions) were observed in women. There was a strong correlation ($p<0.0001$) of inhibition of the increase in plaque volume with increasing age [Koscielny 1999].

In a 3-year randomized study, 432 patients with a history of myocardial infarction were assigned to an oily extract of garlic (n = 222) or placebo (n = 210) daily, in addition to other necessary

medication. Significant reductions in the non-fatal reinfarction rate (44%; p<0.001) and mortality (31%; p<0.01) were observed in patients taking the oily extract of garlic compared to those taking placebo [Bordia 1989].

Respiratory Tract Infections / Common cold
A systematic review revealed insufficient evidence for the use of garlic in preventing or treating the common cold. Of the eight studies identified, only one (Josling 2001) met the inclusion criteria and suggested that garlic may prevent the common cold [Lissiman 2014].

In a randomized, double-blind, placebo-controlled study, a daily dose of 180 mg of stabilized allicin or placebo were given to 146 volunteers for 12 weeks. There were significantly (p<0.001) fewer occurrences of common cold in the garlic group (24) than in the placebo group (65). Symptoms lasted significantly (p<0.001) longer in the placebo group (5.01 days) compared to the garlic group (1.52 days) and there were fewer days of illness in the garlic group (n=111) compared with the placebo group (n=366) [Josling 2001].

In a randomized, double-blind, placebo-controlled, 5-month trial, garlic tablets (300 mg/day; not further specified; n=42) reduced acute respiratory disease morbidity 1.7-fold in children aged 10 to 12 years compared to placebo (n=41) [Andrianova 2003].

Other clinical effects
Other clinical studies of garlic preparations have reported antimycotic and antibacterial effects, such as in women with bacterial vaginosis [Ledezma 2000; Sabitha 2005; Mohammadzadeh 2014].

In a randomized, placebo-controlled study involving 41 patients suffering from hepatopulmonary syndrome, the effect of garlic oil capsules (n=21) was compared to placebo (n=20) over a period of 9 to 18 months. Each garlic capsule contained 250 mg oil and the mean daily garlic dose was 1.55±0.29 g. After 9 months there was a significant (p<0.001) increase in baseline arterial oxygen levels of 24.66% in the garlic group compared to only 7.37% in the placebo group (p=0.02), and a significant (p<0.001) decrease in the alveolar-arterial oxygen gradient in the garlic group (28.35%) compared to placebo (10.73%; p=0.12). The arterial oxygen level and alveolar-arterial oxygen level were also significantly (p<0.001) higher and lower, respectively, in the garlic group compared to the placebo group. Two of 21 patients in the garlic group and 7 of 20 patients in the placebo group died during the follow-up period of up to 18 months [De 2010].

In a randomized, double-blind, placebo-controlled trial, 40 women with metabolic syndrome according to NCEP ATPIII (Adult Treatment Panel III) criteria, and 10 healthy female controls, were treated with 1.8 g garlic tablets per day or placebo for 6 weeks. Compared to placebo, the garlic treatment resulted in a significantly lower weight (p=0.04) and waist circumference (p<0.001) in the women with metabolic syndrome, while no effect was seen in healthy women [Sharifi 2010].

In an open, two phase study involving 30 patients with type-II diabetes, both dry powdered garlic and a dried aqueous extract (dried filtrate of an aqueous macerate), at a dose of 45 mg/kg/d orally for 14 days, significantly (p<0.05) decreased blood glucose levels in patients taking no other medications as well as in patients taking oral hypoglycaemics but with an inadequate control of blood glucose. Lower doses (20 and 30 mg/kg/d) had no significant effect. Glycosuria, found only in the patients not also taking oral hypoglycaemics, was reversed by both garlic preparations at the 45 mg/kg/d dose. There was no significant activity found in a healthy control group (n=15) for either garlic preparation [Waheed 2014].

Various epidemiologic studies have found a negative correlation between the intake or use of garlic and the incidence of cancer [Gao 1999; Munoz 2001; Setiawan 2005; Galeone 2006; Galeone 2007; Zhou 2013; Galeone et al. 2015; Kodali 2015]. A systematic review found 4 randomized controlled trials on the effectiveness of garlic extract for reducing cancer risk. The analyzed studies were of mixed quality, and the findings from these trials were not uniformly positive [Ernst 2012].

In a randomized, placebo-controlled, double-blind trial, the preventive effect of garlic against nosocomial infections was studied in 94 patients in intensive care units. A powdered and dissolved garlic tablet (400 mg/day) or placebo were administered by gavage through nasogastric intubation for 6 days. There were no cases of venous catheter infection in the garlic group and the frequency of positive venous catheter tip cultures was significantly (p=0.03) higher in the placebo group than in the garlic group. There was no significant difference in urinary catheter cultures between the groups [Madineh 2017].

Pharmacokinetic properties
The absorption and excretion of orally administered radio-actively-labelled 35S-alliin, allicin and vinyldithiine were studied in rats. Alliin was absorbed and eliminated much faster than the other compounds. After administration of ^{35}S-alliin at 8 mg/kg b.w. maximum blood concentration was reached after 10 minutes (allicin 30-60 minutes, vinyldithiine 120 minutes). The excretion of alliin equivalents was mainly renal [Lachmann 1991].

The metabolism of allicin was analyzed in perfusion experiments using isolated rat liver. Allicin could be identified after passage through the liver only after administration of high doses (1.2 mg allicin/minute). After administration of 400 µg allicin/minute 95% was metabolized after the first hepatic passage; in this case allicin metabolites such as diallyl disulphide and allyl mercaptan were detected in the liver and gall bladder [Egen-Schwind 1991].

S-allylcysteine orally administered to rats, mice and dogs was rapidly and easily absorbed, and distributed mainly in plasma, liver and kidney; the bioavailability was 98.2% in rats, 103.0% in mice and 87.2% in dogs. It was mainly excreted in the urine as the N-acetyl metabolite in rats, while mice excreted both unchanged and N-acetyl forms [Nagae 1994].

Interactions in animals
Pharmacokinetic interactions between orally administered metformin (320 mg/kg b.w.) and garlic (500 mg/kg b.w.) were studied in rats. Compared to metformin alone, administration of the garlic with metformin for 8 days produced a significant (p-value not given) increase in the C_{max} and AUC_{0-12h}, as well as a slightly higher $t_{1/2}$, of metformin. Furthermore, blood glucose was decreased more with the combination than with metformin alone [Chourey 2011].

Oral pre-treatment of rats with a garlic homogenate (250 mg/kg b.w.) for 30 days enhanced the bioavailabilty of a single oral dose of propranolol (10 mg/kg b.w.). Significant increases in the half-life (p<0.001) and C_{max} (p<0.05) were demonstrated, as well as a significant (p<0.001) reduction in clearance, when compared to propranolol given alone [Asdaq 2011].

Interactions in humans
An increased INR in 2 patients on warfarin was attributed to garlic products as there were no other changes of medication

or habits (no further data) [Sunter 1991]. A decreased INR was reported in a patient on fluindione with concurrent use of garlic (600 mg, no further details) for 12 days [Pathak 2003].

A preparation of garlic (equivalent to approx. 8 g/day; not further defined) was given to 10 healthy volunteers on study days 5-25. Saquinavir was administered on days 1-4, 22-25 and 36-39, and blood samples were obtained on study days 4, 25 and 39. At day 25 as compared to day 4, the mean area under the curve (AUC) of saquinavir was reduced by 51%, the trough levels by 49% and the mean maximum concentrations (C_{max}) by 54%. After a 10-day washout period from garlic (day 39), the AUC, trough, and C_{max} values returned to 60-70% of their values at baseline. However, the decrease was only seen in 6 of the patients; in 3 of the patients an increase was observed. A control group as well as information on nutrition which could influence the bioavailability of saquinavir are missing [Piscitelli 2002].

A garlic preparation (equivalent to 1 g fresh garlic daily), administered for 4 days to 10 volunteers, decreased the $AUC_{0-\infty}$ of a single dose of 400 mg ritonavir by 17% and peak plasma concentration by 1%. The authors concluded that the results should not be extrapolated to steady-state conditions [Gallicano 2003].

Another study in healthy volunteers revealed no significant effects on pharmacokinetic parameters of probe substrates of the CYP2D6 (dextromethorphan) or CYP3A4 (alprazolam) pathway of metabolism after administration of 1800 mg of a garlic extract (1800 µg "potential" allicin) twice daily for 14 days [Markowitz 2003].

The effect of dried garlic powder on blood pressure was studied in a 12-week randomized, double-blind, placebo-controlled trial in 62 healthy volunteers assigned to garlic (920 mg daily, corresponding to 10.8 mg alliin) or placebo. No significant differences in blood pressure were measured between the groups [Turner 2004].

In an open study, 70 hypertensive patients received an oily garlic preparation (1.6 g garlic macerate 1:1; 1.6 mg allicin derivatives) in addition to standard antihypertensive pharmacotherapy for 30 days. A significantly lower level of lipid peroxidation products reacting with thiobarbituric acid (from 4.9±0.9 to 2.8±0.9 µmol/l, $p<0.05$), as compared to the initial values, was measured in the blood [Duda 2008].

In an open pilot study involving 13 elderly healthy adults, daily consumption of garlic (0.1 g/kg b.w.) for one month resulted in significantly lower plasma and erythrocyte malondialdehyde levels (from 381.7±39.8 to 352.2±38.4 nmol/ml, $p<0.05$) and increased activities of the antioxidant enzymes glutathione peroxidase (from 8.34±1.07 to 9.32±0.78 IU/ml) and SOD (from 1,668±495 to 2,065±298 IU/ml, $p<0.05$) as compared to the initial values [Avci 2008].

Preclinical safety data

Acute toxicity
The LD_{50} of an aqueous extract of garlic applied s.c. to rabbits (3 per group) was 3034 mg/kg b.w. and the maximum tolerated dose was 2200 mg/kg b.w. At doses of 3200 and 4200 mg/kg b.w. the extract induced behavioural signs such as loss of appetite, depression, partial paralysis and death (2 of 3 animals at 3200 mg/kg b.w.; 3 of 3 animals at 4200 mg/kg b.w.) [Mikail 2010].

Other investigators, using various non-standardized garlic extracts, reported the lowest oral LD_{50} value in rats and mice as 30 ml/kg for a 14.5% ethanolic extract from fresh bulbs [Nagakawa 1984].

The LD_{50} of an aqueous suspension of powdered garlic administered by oral gavage to mice was determined to be 25 g/kg b.w. [Alqasoumi 2012].

Repeated dose toxicity
Fresh garlic juice orally administered to rats at 5 ml/kg b.w. daily for 3 weeks resulted in reduced weight gain, gastric mucosal damage and in some cases death [Nagakawa 1980].

Daily administration of a raw garlic extract to rats at 200 mg/kg b.w. for 4 weeks resulted in weight loss and a drop in serum protein levels [Shashikanth 1986].

An aqueous extract administered by gavage to rats at doses of 1000, 3000 and 5000 mg/kg b.w. for 14 days did not induce mortality. The increased levels of liver enzymes and bilirubin, and reduced levels of urea and creatinine, were non-significant compared to control. Whereas the low and high doses demonstrated a significant ($p<0.005$) increase in white blood cells. Neither gross pathology nor histopathological analysis revealed any adverse effects [Asiedu-Gyekye 2014].

An aqueous suspension of powdered garlic administered by oral gavage to mice for 90 days, at doses of 37.5 and 75 mg/kg b.w., induced mild to moderate autonomic symptoms such as changes of respiration rate, heart rate and hypothermia, in addition to causing itching, alopecia, agressive behavior and excitation [Alqasoumi 2012].

Mutagenicity
The genotoxicity of orally administered garlic was assessed using the micronucleus test in mice; compared to controls no significant changes were found in the bone marrow cells [Abraham 1984]. No mutagenicity was evident in the Ames test [Yoshida 1984].

In the micronucleus test an aqueous suspension of powdered garlic administered to mice by oral gavage at doses of 250 and 500 mg/kg b.w. did not reveal any significant activity as compared to the control [Alqasoumi 2012].

Clinical safety data
Systematic reviews and meta-analyses have concluded that garlic preparations were well tolerated in all trials with minimal side effects [Ried 2013] and that no serious adverse events were reported in any of the included trials [Xiong 2015].

In a 5-month, open study involving 172 children with acute respiratory disease, there was no difference in the prevalence of gastrointestinal side effects between the groups receiving garlic tablets (not further specified), benzimidazole or placebo [Andrianova 2003].

In published studies involving consumption of up to 1.2 g of garlic powder daily, garlic odour was the most common side effect, with an incidence of up to 50%. However, this effect is not considered to be adverse. Gastrointestinal discomfort was a common adverse effect reported and there have been rare cases of allergic reactions [Hughes 2002; Pires 2002; Izzo 2007; Polat 2007].

In healthy volunteers 10 g of raw garlic consumed daily for 2 months induced no adverse events [Gadkari 1991].

Daily administration of high doses of garlic oil (approx. 120 mg, equivalent to 60 g/day fresh garlic) over a period of 3 months did not result in any toxic effects or adverse events [Bordia 1978].

In 4 cases reduced platelet aggregation and prolonged bleeding time have been reported after intake of raw garlic or garlic powder [Rose et al. 1990; Burnham 1995; German 1995; Carden 2002; Woodbury & Sniecinski 2016], and in one further case also in combination with acetyl salicylic acid and milk thistle tablets (no further details) [Shakeel 2010].

In an 8 week, randomized, single-blind, placebo-controlled study involving 100 women in the third trimester of pregnancy, given either garlic (n=50; 800 mg garlic powder per day, 2 mg allicin) or placebo (n=50), no serious side effects were reported. A slight feeling of nausea was reported in 8 of the garlic group patients and 2 of the placebo patients. An "odour due to garlic" was reported by 34% of the garlic group and 4% of the placebo group [Ziaei 2001].

In a case report, consumption of approx. 6 stir-fried garlic cloves three times per week was associated with HIV virologic failure during treatment with boosted atazanavir [Duncan 2013].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ALOE BARBADENSIS

2014

Barbados Aloes

DEFINITION

Barbados aloes[1] consists of the concentrated and dried juice of the leaves of *Aloe barbadensis* Miller. It contains not less than 28.0 per cent of hydroxyanthracene derivatives, expressed as barbaloin ($C_{21}H_{22}O_9$; M_r 418.4) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [EP].

CONSTITUENTS

The main active constituents are 25-40% of barbaloin, which is a mixture of aloin A (10*S*) and aloin B (10*R*), and their respective 6-O-*p*-coumaroyl esters; 3-4% of 7-hydroxyaloins A and B and their 6-O-*p*-coumaroyl esters (characteristic for Barbados aloes); and 8-O-methyl-7-hydroxyaloins A and B and their 6-O-cinnamoyl esters; all these compounds are aloe-emodin anthrone C-glycosides. Small amounts of the aglycones aloe-emodin and chrysophanol are also present. Other constituents include 5-methylchromone glycosides, mainly the 8-glucosyl derivative aloeresin B with smaller amounts of its coumaroyl and cinnamoyl esters [Sigler 2007; Hiller 2009; Sticher 2010].

CLINICAL PARTICULARS

Therapeutic indications
For short term use in cases of occasional constipation [Schilcher 1979; Sigler 2007; Hiller 2009].

Posology and method of administration

Dosage
The correct individual dosage is the smallest required to produce a comfortable soft-formed motion.

Adults and children over 12 years: preparations equivalent to 10-30 mg of hydroxyanthracene derivatives, calculated as barbaloin, to be taken once daily at night [Sigler 2007; Hiller 2009].

Elderly: dose as for adults.

Not recommended for use in children under 12 years of age.

The pharmaceutical form must allow lower dosages.

Method of administration
For oral administration.

Duration of administration
Stimulant laxatives should not be used for periods of more than 2 weeks without medical advice. If symptoms persist after intake of the preparation medical advice should be sought [Tack 2011].

Contra-indications
Known hypersensitivity; intestinal obstruction and stenosis, atony, inflammatory bowel diseases (e.g. Crohn's disease, ulcerative colitis), appendicitis; abdominal pain of unknown origin; severe dehydration states with water and electrolyte depletion [Schilcher 1979; Reynolds 1996; Hiller 2009; Pasricha 2011].

Special warnings and special precautions for use
As for all laxatives, aloes should not be given when any undiagnosed acute or persistent abdominal symptoms are present.

E/S/C/O/P
MONOGRAPHS

[1]Synonym: Aloe vera

Chronic use of anthraquinone laxatives may cause pigmentation of the colon (pseudomelanosis coli) which is harmless and reversible after drug discontinuation. Abuse, with diarrhoea and consequent fluid and electrolyte losses, may cause disturbance of the water and electrolyte balance (mainly hypokalaemia). A symptom of hypokalaemia is an atonic colon with impaired function (aggravation of constipation). In severe cases hypokalaemia can result in cardiac and neuromuscular dysfunction, especially if cardiac glycosides, diuretics or corticosteroids are taken. Chronic use may result in albuminuria and haematuria.

Long-term use of stimulant laxatives is not recommended. If laxatives are needed every day the cause of the constipation should be investigated. Use of stimulant laxatives for more than 2 weeks should be avoided and requires medical supervision. In chronic constipation, stimulant laxatives are not an acceptable alternative to a change in dietary habits, adequate fluid intake, physical activities and training for normal bowel evacuation [Schilcher 1979; Müller-Lissner 1993, 2005; Reynolds 1996; Nusko 2000; Morales 2009; Sticher 2010; Keller 2011; Pasricha 2011].

Anthraquinone laxatives enhance circulation in the pelvic region and thus are not recommended for patients suffering from haemorrhoids [Frasch 2007; Sigler 2007; Hiller 2009; Sticher 2010].

Not recommended for children under 12 years.

Interaction with other medicaments and other forms of interaction
Hypokalaemia (resulting from long term laxative use) potentiates the action of cardiac glycosides and interacts with antiarrhythmic drugs and with drugs which induce reversion to sinus rhythm (e.g. quinidine). Concomitant use with other drugs inducing hypokalaemia (e.g. thiazide diuretics, adrenocorticosteroids and liquorice root) may aggravate electrolyte imbalance [Sigler 2007].

Pregnancy and lactation

Pregnancy
Not to be taken by pregnant women as there is a greater risk of abortion due to increased circulation in the pelvic region and nervous stimulation of uterine muscles [Frasch 2007; Sigler 2007; Hiller 2009].

Lactation
Not to be taken during breastfeeding as small amounts of active metabolites (rhein) may appear in breast milk [Faber 1988; Sigler 2007; Hiller 2009].

Effects on ability to drive and use machines
None.

Undesirable effects
Abdominal spasms and pain, in particular in patients with irritable colon; yellowish-brown or red (pH dependent) discolouration of urine by metabolites, which is not clinically significant [Ewe 1986; Tedesco 1986; Reynolds 1996; Pasricha 2011; Tack 2011].

Overdose
The major symptoms are griping and severe diarrhoea with consequent losses of fluid and electrolytes, which should be replaced [Pasricha 2011]. Treatment should be supportive with generous amounts of fluid. Electrolytes, especially potassium, should be monitored; this is particularly important in the elderly and the young.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

1,8-dihydroxyanthracene derivatives possess a laxative effect [Fairbairn 1965, 1970]. Aloins A and B and 7-hydroxyaloins A and B are precursors which are not absorbed in the upper gut. Studies in conventional and germ-free animals have established that glycosidases from the intestinal flora are responsible for the breakdown of glycosides. The ability to metabolize various anthranoids varies greatly across species depending upon the composition of intestinal flora [Dreessen 1988; de Witte 1993; Sigler 2007]. In humans, anthranoid glycosides ingested orally pass into the colon unmodified. Human intestinal flora is able to break down O-glycosides easily, but only to some extent the C-glycosides of most anthranoids [Hattori 1988; Che 1991]. The main active metabolite is aloe-emodin-9-anthrone, which acts specifically on the colon [Ishii 1990].

There are different mechanisms of action:

(i) reduced resorption of sodium and water and an influence on the motility of the large intestine (inhibition of the Na^+/K^+ pump and of Cl^- channels at the colonic membrane) resulting in accelerated colonic transit [Ishii 1990; Hönig 1992; Rauwald 1992; Wanitschke 2003; Hiller 2009], and

(ii) an influence on secretion processes (stimulation of mucus and chloride secretion) resulting in enhanced fluid secretion [Ishii 1990, 1994a, 1994b; Wanitschke 2003].

(iii) direct and indirect stimulation of colonic neurons (indirect stimulation by prostaglandins) resulting in enhanced motility [Capasso 1983; Ishii 1990; Wintola 2010; Teuscher 2012].

Due to the time taken for transport to the colon and metabolism into the active compounds, defecation may take place after a delay of 6-12 hours [Sigler 2007; Müller-Lissner 2009; Pasricha 2011].

Anti-tumour activity
Isolated aloe-emodin specifically inhibited the growth of neuroectodermal tumour cell lines at ED_{50} of 1-13 µg *in vitro*. However, no effect was shown on other tumour cell lines or by aloe-emodin glycosides, which was explained by a unique drug uptake of aloe-emodin in neuroectodermal tumour cells. These results were confirmed by further experiments in rats [Pecere 2000].

In two human hepatic cancer cell lines, Hep G2 and Hep 3B, aloe-emodin inhibited cell proliferation by different mechanisms [Kuo 2002]. Aloe-emodin was also shown to inhibit the growth of Merkel carcinoma cells [Wassermann 2002]. In isolated rat hepatocytes, a cytoprotective effect of aloes extract against 1,4-naphthoquinone-induced toxicity was demonstrated [Norikura 2002].

Pharmacokinetic properties

Aloins A and B as well as hydroxyaloins A and B are C-glycosides which pass directly into the large intestine without breakdown in the stomach or the jejunum. At their site of action, the colon and rectum, they are metabolized by bacterial enzymes into the active anthrone compounds. It has been shown that *Eubacterium* sp. BAR isolated from human faeces is capable of transforming aloin A into the active metabolite aloe-emodin-9-anthrone. This bacterial strain is necessary to cause aloin A-induced diarrhoea in the rat [Hattori 1988; Schulz 1993; Morales 2009; Sticher 2010].

In a human pharmacokinetic study performed with Cape aloes (equivalent to 16.4 mg of hydroxyanthracene derivatives) administered orally for 7 days, aloe-emodin was detected as a metabolite in the plasma only sporadically and with maximum concentrations of less than 2 ng/ml. In the same study rhein was detected in the plasma in concentrations ranging from 6-28 ng/ml (median c_{max} 13.5 ng/ml at median t_{max} 16 h) after single dose administration. In 7-day administration there was no evidence of accumulation of rhein [Schulz 1993].

Using an Ussing-type chamber with rat colonic mucosa as test system, isolated aloe emodin anthrone significantly increased the permeation of the poorly permeable compound 5(6)-carboxyfluorescein [Kai 2002]. Isolated rhein and danthrone enhanced permeation of furosemide in a Caco-2 cell monolayer test system [Laitinen 2007].

In vitro studies on various membrane models confirmed membrane-related effects of barbaloin. Measurements of the phospholipid/water partition coefficient of barbaloin, and investigations on its influence on membrane thermotropic behaviour, illustrated barbaloin's high affinity for phospholipid membranes. Barbaloin induced leakage of intraliposomal carboxyfluorescein, and the antimicrobial effect of barbaloin-containing liposomes were traced back to interaction of this anthraquinone [Alves 2004].

In vitro absorption studies demonstrated that 5-14 % of aloin, aloe-emodin and aloesin were absorbed directly from the gut [Park 2009].

From another study it was concluded that free anthranoids absorbed systemically in humans are partly excreted in the urine as rhein or as conjugates [Vyth 1979].

Systemic metabolism of free anthranoids depends upon their ring constituents [de Witte 1988; Sendelbach 1989]. In the case of aloe-emodin, it has been shown in animal experiments that at least 20-25% of an oral dose will be absorbed. The bioavailability of aloe-emodin is much lower than the absorption, because it is quickly oxidized to rhein and an unknown metabolite, or conjugated. Maximum plasma values of aloe-emodin were reached 1.5-3 hours after administration [Lang 1993]. Elimination of anthranoid metabolites occurs mainly via faeces, but also renally as glucuronides and sulphates [Teuscher 2012].

Preclinical safety data
No specific toxicity was observed when aloes extract (up to 50 mg/kg daily for 12 weeks) and aloin (100 mg/kg daily for 20 weeks) were administered orally to mice [Siegers 1986,1993].

Aloes fermentation products, which contain higher amounts of aloin A and B and less glucans compared to unfermentated aloe preparations, were administered orally to rats at doses of 1, 2 or 5 g/kg for single-dose toxicity tests, and at 0.5, 1 or 2 g/kg for repeated-dose toxicity tests. Treatment, even at high dose levels, did not affect function of the autonomic nervous system, general behavior, reaction, vigilance, mortality, body weight, feed and water intake, nor haematological and histopathological parameters [Cho 2011].

There was no evidence of any embryolethal, teratogenic or foetotoxic effects in rats after oral treatment with aloes extract (up to 1000 mg/kg b.w./day) or aloin (up to 200 mg/kg b.w./day) [Bangel 1975].

Results from *in vitro* (gene mutation and chromosome aberration) tests and *in vivo* (micronucleus test in mice bone marrow cells) genotoxicity studies performed with various aloes preparations and isolated constituents, as well as human and animal pharmacokinetic data, indicate no genotoxic risk [Brown 1979, 1980; Westendorf 1988, 1990; Wölfle 1990; CCR 1992a, 1992b, 1992c; Heidemann 1993].

In a 2-year study, male and female F344/N rats were exposed to 280, 830 or 2500 ppm of emodin in the diet, corresponding to an average daily dose of emodin of 110, 320 or 1000 mg/kg b.w. in male rats and 120, 370 or 1100 mg/kg in female rats. No evidence of carcinogenic activity of emodin was observed in male rats. A marginal increase in the incidence of Zymbal's gland carcinoma occurred in female rats treated with the high dosage but was interpreted as questionable [NIH 1999].

In a further 2-year study, on $B6C3F_1$ mice, males were exposed to 160, 312 or 625 ppm of emodin (corresponding to an average daily dose of 15, 35 or 70 mg/kg b.w.) and females to 312, 625 or 1250 ppm of emodin (corresponding to an average daily dose of 30, 60 or 120 mg/kg). There was no evidence of carcinogenic activity in female mice. A low incidence of renal tubule neoplasms in exposed males was not considered relevant [NIH 1999].

Aloin fed to mice in the diet at a level of 100 mg/kg/day for 20 weeks did not promote dimethylhydrazine-induced colorectal tumours [Siegers 1993].

The data from *in vivo* studies concerning the carcinogenic risk of aloe in rats are supported by studies on herbal stimulant laxatives containing senna extract, with similar anthroquinone constituents. Senna preparations showed no carcinogenic or genotoxic effect, and from studies in rats no connection to tumours occurred [Lydén-Sokolowski 1993; Morales 2009].

Clinical safety data
In a case control study with retrospective and prospective evaluation, no causal relationship between anthranoid laxative use and colorectal cancer could be detected [Loew 1994a, 1994b].

In another prospective case control study involving 202 patients with colorectal carcinomas, 114 patients with adenomas and 238 patients in the control group, an association between the use of anthranoid laxatives and the development of colorectal adenoma or carcinoma could not be shown [Nusko 2000].

A longer-term use of laxatives has been recommended in chronic constipation [Andresen 2013].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

Front cover
Title page
Verso
Foreword and Preface
Notes for the Reader
Abbreviations

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ALOE CAPENSIS

2014

Cape Aloes

DEFINITION

Cape aloes consists of the concentrated and dried juice of the leaves of various species of *Aloe*, mainly *Aloe ferox* Miller and its hybrids. It contains not less than 18.0 per cent of hydroxyanthracene derivatives, expressed as barbaloin ($C_{21}H_{22}O_9$; M_r 418.4) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [EP].

CONSTITUENTS

The main active constituents are 13-27% barbaloin, which is a mixture of aloin A (10*S*) and aloin B (10*R*), the aloe-emodin anthrone C-glycoside 5-hydroxyaloin A (characteristic for Cape aloes) and the anthrone C- and O-glycosides aloinosides A and B [Rauwald 1993a, 1993b]. Other constituents include 2-acetonyl-5-methylchromones (also known as aloeresins), small quantities of 1.8-dihydroxyanthraquinones (e.g. aloe-emodin), cinnamic acid and 1-methyl-tetralin derivatives [Sigler 2007; Hiller 2009; Sticher 2010; Chen 2012].

CLINICAL PARTICULARS

Therapeutic indications
For short term use in cases of occasional constipation [Schilcher 1979; Sigler 2007; Hiller 2009].

Posology and method of administration

Dosage

The correct individual dosage is the smallest required to produce a comfortable soft-formed motion.

Adults and children over 12 years: preparations equivalent to 10-30 mg of hydroxyanthracene derivatives, calculated as barbaloin, to be taken once daily at night [Sigler 2007; Hiller 2009].

Elderly: dose as for adults.

Not recommended for use in children under 12 years of age.

The pharmaceutical form must allow lower dosages.

Method of administration
For oral administration.

Duration of administration
Stimulant laxatives should not be used for periods of more than 2 weeks without medical advice. If symptoms persist after intake of the preparation medical advice should be sought [Tack 2011].

Contra-indications
Known hypersensitivity; intestinal obstruction and stenosis, atony, inflammatory bowel diseases (e.g. Crohn's disease, ulcerative colitis), appendicitis; abdominal pain of unknown origin; severe dehydration states with water and electrolyte depletion [Schilcher 1979; Reynolds 1996; Hiller 2009; Pasricha 2011].

Special warnings and special precautions for use
As for all laxatives, aloes should not be given when any undiagnosed acute or persistent abdominal symptoms are present.

E/S/C/O/P
MONOGRAPHS

Chronic use of anthraquinone laxatives may cause pigmentation of the colon (pseudomelanosis coli) which is harmless and reversible after drug discontinuation. Abuse, with diarrhoea and consequent fluid and electrolyte losses, may cause disturbance of the water and electrolyte balance (mainly hypokalaemia). A symptom of hypokalaemia is an atonic colon with impaired function (aggravation of constipation). In severe cases hypokalaemia can result in cardiac and neuromuscular dysfunction, especially if cardiac glycosides, diuretics or corticosteroids are taken. Chronic use may result in albuminuria and haematuria.

Long-term use of stimulant laxatives is not recommended. If laxatives are needed every day the cause of the constipation should be investigated. Use of stimulant laxatives for more than 2 weeks should be avoided and requires medical supervision. In chronic constipation, stimulant laxatives are not an acceptable alternative to a change in dietary habits, adequate fluid intake, physical activities and training for normal bowel evacuation [Schilcher 1979; Müller-Lissner 1993, 2005; Reynolds 1996; Nusko 2000; Morales 2009; Sticher 2010; Keller 2011; Pasricha 2011].

Anthraquinone laxatives enhance circulation in the pelvic region and thus are not recommended for patients suffering from haemorrhoids [Frasch 2007; Sigler 2007; Hiller 2009; Sticher 2010].

Not recommended for children under 12 years.

Interaction with other medicaments and other forms of interaction
Hypokalaemia (resulting from long term laxative use) potentiates the action of cardiac glycosides and interacts with antiarrhythmic drugs and with drugs which induce reversion to sinus rhythm (e.g. quinidine). Concomitant use with other drugs inducing hypokalaemia (e.g. thiazide diuretics, adrenocorticosteroids and liquorice root) may aggravate electrolyte imbalance [Sigler 2007].

Pregnancy and lactation

Pregnancy
Not to be taken by pregnant women as there is a greater risk of abortion due to increased circulation in the pelvic region and nervous stimulation of uterine muscles [Frasch 2007; Sigler 2007; Hiller 2009].

Lactation
Not to be taken during breastfeeding as small amounts of active metabolites (rhein) may appear in breast milk [Faber 1988; Sigler 2007; Hiller 2009].

Effects on ability to drive and use machines
None.

Undesirable effects
Abdominal spasms and pain, in particular in patients with irritable colon; yellowish-brown or red (pH dependent) discolouration of urine by metabolites, which is not clinically significant [Ewe 1986; Tedesco 1986; Reynolds 1996; Pasricha 2011; Tack 2011].

Overdose
The major symptoms are griping and severe diarrhoea with consequent losses of fluid and electrolytes, which should be replaced [Pasricha 2011]. Treatment should be supportive with generous amounts of fluid. Electrolytes, especially potassium, should be monitored; this is particularly important in the elderly and the young.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties
1,8-dihydroxyanthracene derivatives possess a laxative effect [Fairbairn 1965, 1970]. Aloins A and B, 5-hydroxyaloin A and the aloinosides A and B are precursors which are not absorbed in the upper gut. Studies in conventional and germ-free animals have established that glycosidases from the intestinal flora are responsible for the breakdown of glycosides. The ability to metabolize various anthranoids varies greatly across species depending upon the composition of intestinal flora [Dreessen 1988; de Witte 1993; Sigler 2007]. In humans, anthranoid glycosides ingested orally pass into the colon unmodified. Human intestinal flora is able to break down O-glycosides easily but only to some extent C-glycosides of most anthranoids [Hattori 1988; Che 1991]. The main active metabolite is aloe-emodin-9-anthrone, which acts specifically on the colon [Ishii 1990].

There are different mechanisms of action:

(i) reduced resorption of sodium and water and an influence on the motility of the large intestine (inhibition of the Na^+/K^+ pump and of Cl^- channels at the colonic membrane) resulting in accelerated colonic transit [Ishii 1990; Hönig 1992; Rauwald 1992; Wanitschke 2003; Hiller 2009], and

(ii) an influence on secretion processes (stimulation of mucus and chloride secretion) resulting in enhanced fluid secretion [Ishii 1990, 1994a, 1994b; Wanitschke 2003].

(iii) direct and indirect stimulation of colonic neurons (indirect stimulation by prostaglandins) resulting in enhanced motility [Capasso 1983; Ishii 1990; Wintola 2010; Teuscher 2012].

Due to the time taken for transport to the colon and metabolism into the active compounds defecation may take place after a delay of 6-12 hours [Sigler 2007; Müller-Lissner 2009; Pasricha 2011].

Anti-tumour activity
Isolated aloe-emodin specifically inhibited the growth of neuroectodermal tumor cell lines at ED_{50} of 1-13 µg in vitro. However, no effect could be shown on other tumor cell lines or by aloe-emodin glycosides, which was explained by a unique drug uptake of aloe emodin in neuroectodermal tumour cells. These results were confirmed by further experiments in rats [Pecere 2000].

In two human hepatic cancer cell lines, Hep G2 and Hep 3B, aloe-emodin inhibited cell proliferation by different mechanisms [Kuo 2002]. Aloe-emodin was also shown to inhibit the growth of Merkel carcinoma cells [Wassermann 2002]. In isolated rat hepatocytes, a cytoprotective effect of aloes extract against 1.4-naphthoquinone-induced toxicity was demonstrated [Norikura 2002; Chen 2012].

An ethanolic fraction of Cape aloes was reported to have anti-tumour activity *in vivo* against Sarcoma 180 and Ehrlich ascites cancer cells [Soeda 1969]. After a screening of 31different plants, aloes extract showed strong growth inhibiting effects on Ehrlich ascites tumor cells (EATC). From subsequent *in vitro* studies with Cape aloes dichloromethane extract it was concluded that constituents of aloes contribute synergistically to this effect. Aloe-emodin has no growth-inhibiting effect on EATC but enhanced the effect of the other constituents of the extract [Kametani 2007].

Pharmacokinetic properties
Aloins A and B as well as hydroxyaloins A and B are C-glycosides which pass directly into the large intestine without breakdown

in the stomach or the jejunum. At their site of action, the colon and rectum, they are metabolized by bacterial enzymes into the active anthrone compounds. It has been shown that *Eubacterium* sp. BAR isolated from human faeces is capable of transforming aloin A into the active metabolite aloe-emodin-9-anthrone. This bacterial strain is necessary to cause aloin A-induced diarrhoea in the rat [Hattori 1988; Schulz 1993; Morales 2009; Sticher 2010].

In a human pharmacokinetic study performed with Cape aloes (equivalent to 16.4 mg of hydroxyanthracene derivatives) administered orally for 7 days, aloe-emodin was detected as a metabolite in the plasma only sporadically and with maximum concentrations of less than 2 ng/ml. In the same study rhein was detected in the plasma in concentrations ranging from 6-28 ng/ml (median c_{max} 13.5 ng/ml at median t_{max} 16 h) after single dose administration. In 7-day administration there was no evidence of accumulation of rhein [Schulz 1993].

Using an Ussing-type chamber with rat colonic mucosa as the test system, isolated aloe-emodin anthrone significantly increased the permeation of poorly the permeable compound 5(6)-carboxyfluorescein [Kai 2002]. Isolated rhein and danthrone enhanced permeation of furosemide in a Caco-2 cell monolayer test system [Laitinen 2007].

In vitro studies on various membrane models confirmed membrane-related effects of barbaloin. Measurements of the phospholipid/water partition coefficient of barbaloin, and investigations on its influence on membrane thermotropic behaviour, illustrated barbaloin's high affinity for phospholipid membranes. Barbaloin-induced leakage of intraliposomal carboxyfluorescein and the antimicrobial effect of barbaloin-containing liposomes were traced back to the membrane interaction of this anthraquinone [Alves 2004].

In vitro absorption studies demonstrated that 5-14 % of aloin, aloe-emodin and aloesin were absorbed directly from the gut [Park 2009].

From another study it was concluded that free anthranoids absorbed systemically in humans are partly excreted in the urine as rhein or as conjugates [Vyth 1979].

Systemic metabolism of free anthranoids depends upon their ring constituents [de Witte 1988; Sendelbach 1989]. In the case of aloe-emodin, it has been shown in animal experiments that at least 20-25% of an oral dose will be absorbed. The bioavailability of aloe-emodin is much lower than the absorption, because it is quickly oxidized to rhein and an unknown metabolite, or conjugated. Maximum plasma values of aloe-emodin were reached 1.5-3 hours after administration [Lang 1993]. Elimination of anthranoid metabolites occurs mainly via faeces, but also renally as glucuronides and sulphates [Teuscher 2012].

Preclinical safety data
No specific toxicity was observed when aloes extract (up to 50 mg/kg daily for 12 weeks) and aloin A (up to 60 mg/kg daily for 20 weeks) were administered orally to mice [Siegers 1986, 1993].

Aloes fermentation products, which contain higher amounts of aloin A and B and less glucans compared to unfermentated aloe preparations, were administered orally to rats at doses of 1, 2 or 5 g/kg for single-dose toxicity tests, and at 0.5, 1 or 2 g/kg for repeated-dose toxicity tests. Treatment, even at high dose levels, did not affect function of the autonomic nervous system, general behavior, reaction, vigilance, mortality, body weight, feed and water intake, nor in haematological and histopathological parameters [Cho 2011].

There was no evidence of any embryolethal, teratogenic or foetotoxic effects in rats after oral treatment with aloes extract (up to 1000 mg/kg b.w./day) or aloin A (up to 200 mg/kg b.w./day) [Bangel 1975].

Results from *in vitro* (gene mutation and chromosome aberration) tests and *in vivo* (micronucleus test in mice bone marrow cells) genotoxicity studies as well as human and animal pharmacokinetic data indicate no genotoxic risk from Cape aloes [Brown 1979, 1980; Morimoto 1982; Bootman 1987a, 1987b; Marquardt 1987; Westendorf 1988, 1990, 1993; Wölfle 1990; CCR 1992a, 1992b, 1992c; Heidemann 1993; Lang 1993].

In a 2-year study, male and female F344/N rats were exposed to 280, 830 or 2500 ppm of emodin in the diet, corresponding to an average daily dose of emodin of 110, 320 or 1000 mg/kg b.w. in male rats and 120, 370 or 1100 mg/kg in female rats. No evidence of carcinogenic activity of emodin was observed in male rats. A marginal increase in the incidence of Zymbal's gland carcinoma occurred in female rats treated with the high dosage but was interpreted as questionable [NIH 1999].

In a further 2-year study, on $B6C3F_1$ mice, males were exposed to 160, 312 or 625 ppm of emodin (corresponding to an average daily dose of 15, 35 or 70 mg/kg b.w.) and females to 312, 625 or 1250 ppm of emodin (corresponding to an average daily dose of 30, 60 or 120 mg/kg). There was no evidence of carcinogenic activity in female mice. A low incidence of renal tubule neoplasms in exposed males was not considered relevant [NIH 1999].

Aloin fed to mice in the diet at a level of 100 mg/kg/day for 20 weeks did not promote dimethylhydrazine-induced colorectal tumours [Siegers 1993].

The data from *in vivo* studies concerning the carcinogenic risk of aloe in rats can be supported by studies on herbal stimulant laxatives containing senna extract, another anthraquinone containing plant with similar constituents. Senna preparations showed no carcinogenic or genotoxic effect, and from studies in rats no connection to tumours could be identified [Lydén-Sokolowski 1993; Morales 2009].

Clinical safety data
In a case control study with retrospective and prospective evaluation, no causal relationship between anthranoid laxative use and colorectal cancer could be detected [Loew 1994a, 1994b].

In another prospective case control study involving 202 patients with colorectal carcinomas, 114 patients with adenomas and 238 patients in the control group, no association between the use of anthanoid laxatives and the development of colorectal adenoma or carcinoma was shown [Nusko 2000].

A longer-term use of laxatives has been recommended in chronic constipation [Andresen 2013].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

Plant illustrated on the cover: *Althaea officinalis*

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ALTHAEAE RADIX

2019

Marshmallow Root

DEFINITION

Marshmallow root consists of the peeled or unpeeled, whole or cut, dried root of *Althaea officinalis* L. It has a swelling index of minimum 10, determined on the powdered herbal drug.

The material complies with the monograph of the European Pharmacopoeia [Marshmallow Root].

CONSTITUENTS

Characteristic constituents of the dried root are mucilage polysaccharides (from 5% up to 20% in late autumn and winter, in biennial roots), consisting of rhamnogalacturonans (≤30%), arabinans, glucans and arabinogalactans [Franz 1966; Karawya 1971; Tomoda 1977; Tomoda 1980; Capek 1983; Akhtardzhiev 1984; Rosík 1984; Capek 1984; Shimizu 1985; Capek 1987; Capek 1988; Evans 1996; Nosalova 2005; Blaschek 2014]. The mucilage can withstand temperatures of 40-60°C [Franz 1990].

Other constituents include flavone glycosides (ca. 0.2% as aglycones) [Gudej 1990; Shah 2011], mainly isoscutellarein 4′-methyl ether 8-glucoside-2″-sulphate, 4 sulfated hypolaetin-glucosides, phenolic acids, the coumarin scopoletin, fatty acids: linolenic acid (omega 3) and hexadecanoic acid [Gudej 1991; Ninov 1992; Valiei 2011; Sendker 2017], starch, pectin [Evans 1996; Blaschek 2014] and tannins [Bieloszabska 1966].

CLINICAL PARTICULARS

Therapeutic indications

a) Dry cough; irritation of the oral or pharyngeal mucosa [Braun 1987; Weiss 1991; Bradley 1992; Bone 1993; Barnes 2002; Sweetman 2002; Schulz 2004; Fasse 2005; Rouhi 2007; Wichtl 2009; Blaschek 2014].

b) For symptomatic relief of mild gastrointestinal discomfort and irritation of the gastric mucosa [Villar 1984; Schilcher 2003; Bäumler 2007; Blaschek 2014].

In these indications, efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

a) Internal use for dry cough and irritation of the oral mucosa.

Adult single and daily dose:
- 0.5-3 g herbal substance as an aqueous cold macerate* (several times daily up to an equivalent of 15 g of the drug).
- 10 ml of syrup (DER 1:20), repeated up to 6 times daily [Bradley 1992; Schilcher 2003; Schulz 2004; Wichtl 2009; Blaschek 2014].

Daily dose for children, between 6 and 12 years of age, for dry cough:
- 0.5-1.5 g as a macerate*, up to 3 times daily.
- 5-10 ml of syrup (DER 1:20), up to 4-6 times daily. [Weiss 1999; Schilcher 2003; Fasse 2005].

Daily dose for children, between 3 and 6 years of age, for dry cough:
- 0.5-1 g as a macerate*, up to 3 times daily.
- 2.5-5 ml of syrup (DER 1:20), up to 4-6 times daily. [Weiss 1999; Schilcher 2003; Fasse 2005].

E/S/C/O/P MONOGRAPHS

b) Internal use for gastrointestinal irritation.

Adult single and daily dose:
- 3-5 g herbal substance, as an aqueous cold macerate*, up to 3 times daily
  [Bradley 1992; Schilcher 2003; Wichtl 2009].

* To make a macerate pour 150 ml of water (max. temp. 40°C) over one dose of comminuted marshmallow root. Steep for 30 min., stirring frequently. The filtered macerate should be used immediately after preparation.

Method of administration
For oral administration.

Duration of administration
If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.

Special warnings and special precautions for use
For dry cough: the use in children under 3 years of age is not recommended [Fasse 2005].

Interaction with other medicinal products and other forms of interaction
The absorption of other drugs taken simultaneously may be retarded [Barnes 2002; Blaschek 2014]. As a precaution, marshmallow root should be taken ½ to 1 hour before or 2 hours after intake of other medicinal products.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation, without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties
The mucilage from marshmallow root covers the mucosa, especially of the mouth and pharynx, and the gastric mucosa, protecting them from local irritation [Meyer 1956; Müller-Limmroth 1980; Braun 1987; Franz 1989; Weiss 1999; Schulz 2004; Wichtl 2009; Shah 2011; Blaschek 2014].

In vitro experiments

Antimicrobial activity
A dry methanol extract (15 g extracted, filtered and evaporated) demonstrated significant antibacterial activity against periodontal pathogenic bacteria resident in the oral cavity (*Porphyromonas gingivalis*, *Prevotella* spp., *Actinomyces* spp.). The MIC for 9/12 strains was ≤3125 mg/L [Iauk 2003].

Antimicrobial activity against *Pseudomonas aeruginosa*, *Proteus vulgaris* and *Staphylococcus aureus* has been documented for chloroform and methanol extracts of marshmallow root [Recio 1989].

Good antimicrobial activity was reported for hexane extracts containing mainly fatty acids and hexadecanoic acid methylester. The strongest antibacterial effects, by zone of inhibition (mm), were demonstrated for *Bacillus subtilis* (18.9 mm), *Staphylococcus aureus* (16.8 mm), *S. epidermidis* (17.3 mm) and *Escherichia coli* (16.0 mm). Antifungal effects were observed against *Candida albicans* (14.7 mm) and *Saccharomyces cerevisiae* (14.7 mm) [Valiei 2011].

Protection of mucilage
Mucociliary transport in isolated, ciliated epithelium of the frog oesophagus was inhibited up to 17% by 200 µl of a cold, 30-minute macerate of marshmallow root (6.4 g/140 ml) [Müller-Limmroth 1980].

In a study of the bioadhesive effects of purified polysaccharides (>95%) on isolated porcine buccal membranes, polysaccharides from marshmallow root showed dose dependent moderate adhesion to epithelial tissue [Schmidgall 2000].

A dried cold aqueous extract (100 g powdered root yielding 9.9 g (w/w) dry extract), at 10 µg/ml, stimulated cell viability (marginally) and proliferation (significantly, $p<0.01$) of human epithelial cells. Isolated polysaccharides, at 10 µg/ml, significantly ($p<0.01$) increased cell viability but not proliferation. Primary dermal human fibroblasts were not stimulated by the extract or the polysaccharides. Fluorescence-labelled-polysaccharides were detected inside epithelial cells with detectable changes in cell physiology. The fibroblasts did not demonstrate any internalisation, but were found to be covered with a bioadhesive layer of polysaccharides [Deters 2010].

A 50% methanolic extract, depleted of high molecular weight material by alcohol precipitation, yielded 8.1% plant material (relative to the dried drug) in a raw extract. This low molecular weight raw extract contained, among others, flavonoid glycosides, four hypolaetin glycosides and coumarins. The raw extract inhibited human hyaluronidase-1 activity (expressed on *E. coli*) and hyaluronidase mRNA expression in keratinocytes (representing skin and mucosal epithelial cells) at 125 and 250 µg/ml [Sendker 2017].

The bioadhesive properties of 2 mucopolysaccharide-containing aqueous marshmallow root extracts, added to 2 commercial cough syrups (syrup 1: 2.5 g extract (DER: 7-9:1) in 100 ml syrup; syrup 2: 35.6 g extract (DER: 1:19.5-23.5) in 100 g syrup), were investigated in isolated porcine buccal mucosa (attached to glass plates) kept humid by artificial saliva, which was also used as a control solution. The positive adherence of these 2 syrups (coloured with eosin) to porcine mucosa was demonstrated by measuring a reduction in flow-velocity (6% flow for syrup 1; 25% flow for syrup 2) compared to the control solution which did not demonstrate any adhesive properties (100% flow). A subsequent experiment, using the same 2 marshmallow extract-containing syrups and an identical mucosal test system, measured inhibition of caffeine transport through the mucosa (a protective property). Both syrups inhibited caffeine transport: syrup 1 by 30% and syrup 2 by 10%; compared to 100% transport of caffeine alone. A control marshmallow extract (DER: 7-9:1) showed only slight inhibition, indicating that the galenic composition of the syrup supports the inhibitory activity of the marshmallow polysaccharides [Appel 2018].

Immunological activity and effects on melanocytes and keratinocytes
An acidic polysaccharide isolated from marshmallow root, althaea-mucilage O, exhibited weak anti-complement activity (alternative route) in normal human serum at concentrations of 100-1000 µg/ml [Yamada 1985].

A filtered extract (dissolved in 45% 1,3-butylene glycol) was found to inhibit intracellular calcium mobilization in normal human melanocytes (involved in pigmentation) and to strongly inhibit endothelin-1 induced proliferation of melanocytes. The extract also reduced the secretion of endothelin-1 in normal human keratinocytes. The authors suggest that because of these effects, the extract may be a useful ingredient in a whitening agent [Kobayashi 2002].

Pronounced antioxidant activity (tests: ABTS+ radical cation scavenging assay; hypochlorous acid scavenging assay; trolox as positive control) of ethanol/water extracts (50:50 and 70:30 V/V) of marshmallow root (100 mg/ml) was found to correlate well with the phenolic and flavonoid content of the extracts [Benbassat 2013].

In vivo experiments
Mucilaginous herbs like marshmallow root may inhibit coughing by forming a protective coating on the mucosal lining of the respiratory tract, shielding it from irritants.

Antitussive effects
Extracts from marshmallow root and isolated mucilage polysaccharides were administered orally to cats at doses of 50 or 100 mg/kg b.w. in order to investigate their antitussive effects in comparison with controls. Both the extract and isolated polysaccharides, as well as syrupus Althaeae (1000 mg/kg), significantly diminished the intensity and amount of coughing induced by mechanical irritation [Nosalova 1992a, 1992b, 1993].

Cats (with experimentally induced cough reflex, induced by mechanical stimulation of the airway mucosa) were treated orally with either a syrup (1 g/kg b.w.), or an aqueous extract (1 g/kg), or root mucilage (prepared as a crude mixture of polysaccharides obtained by precipitation of the aqueous extract with ethanol and subsequent dialysis of the precipitate; 100 mg/kg), or with isolated rhamnogalacturonan (50 mg/kg). These were compared to commonly used cough suppressants, both a narcotic (codeine at 10 mg/kg) and a non-narcotic drug (dropropizine at 100 mg/kg). The marshmallow-derived polysaccharides exhibited impressive antitussive activity after 30 min., 1, 2 and up to 5 hours, for various cough-related parameters. Rhamnogalacturonan was 2.5 times more active than the other marshmallow preparations [Nosalova 2005].

Antitussive activity of the marshmallow polysaccharide, rhamnogalacturonan, was shown to be dose dependent (25 mg/kg and 50 mg/kg b.w.), when given orally to unsensitized guinea pigs, with experimental citric acid aerosol-induced airways inflammation. The highest oral rhamnogalacturonan dose with strong cough reflex suppressant activity was comparable to the effect of codeine at 10 mg/kg b.w. This dose suppressed the cough reflex significantly ($p \leq 0.01$) up to 5 hours after application [Sutovska 2011].

Anti-inflammatory effects
An ointment containing an aqueous marshmallow root extract (20%), applied topically to the external ear of rabbits, reduced irritation induced by ultraviolet irradiation or tetrahydrofurfuryl alcohol; the anti-inflammatory effect was less than that of an ointment containing dexamethasone (0.05%). An ointment containing both active ingredients at these levels had an anti-inflammatory effect superior to that of the individual active ingredients [Beaune 1966].

On the other hand, a dry 80%-ethanolic extract, administered orally at 100 mg/kg b.w., did not inhibit carrageenan-induced rat paw oedema [Mascolo 1987].

Hypolaetin 8-glucoside has been shown to possess anti-inflammatory activity [Alcaraz 1989; Villar 1987; Villar 1984]. When administered i.p. at 90 mg/kg b.w., it dose-dependently inhibited carrageenan-induced rat paw oedema by 74% after 3 hours ($p<0.01$) compared to 49% inhibition by phenylbutazone at the same dose. The anti-inflammatory effect of hypolaetin 8-glucoside declined more rapidly than that of phenylbutazone, but gastric erosions were only seen after phenylbutazone [Villar 1984]. Hypolaetin 8-glucoside also showed gastric anti-ulcer activity in rats [Alcaraz 1988] and was more potent than troxerutin in inhibiting histamine-induced capillary permeability in rats [Villar 1987].

Hypoglycaemic activity
Mucilage polysaccharides isolated from marshmallow root and administered intraperitoneally to mice at doses of 10, 30 and 100 mg/kg reduced plasma glucose levels respectively to 74%, 81% and 65% of the control level after 7 hours, demonstrating significant hypoglycaemic activity [Tomoda 1987].

Phagocytic activity, immunemodulatory effect
Isolated mucilage polysaccharides from marshmallow root, administered intraperitoneally to mice at 10 mg/kg, produced a 2.2-fold increase in phagocytic activity of macrophages in the carbon-clearance test [Wagner 1985; Hänsel 2014].

Clinical studies
In a randomized, double-blind, placebo-controlled clinical study 63 adults suffering from dry cough, associated with angiotensin-converting enzyme inhibitors, were assessed using a cough score of 0 to 4 (0 = no cough, 1 = tickling in throat; 2 = mild cough; 3 = moderate tolerable cough; 4 = severe persistent cough). The patients were randomized to receive 20 drops 3 times per day of either a marshmallow root preparation (not further defined) or a placebo for 4 weeks. After 4 weeks the severity of cough in the marshmallow group was significantly ($p<0.05$) reduced. Eight patients in the marshmallow group showed almost complete abolition of cough, as opposed to 1 patient in the placebo group. Three patients were excluded from the study because of noncompliance with the test drug [Rouhi 2007].

In a postmarkeing surveillance study, 313 children in 3 groups (0-3 y, n=100; 3-6y, n=115; 6-12y, n=98) were treated 4-6 times daily with 2.5, 5 and 10 ml (according to their age group) of mashmallow root syrup (Phytohustil®; DER: 1:20). Duration of treatment was three days for ¾ of the patients and was continued longer for the remaining ¼ (2.2% were treated for < 3 days). Three children were excluded from efficacy evaluation due to disallowed concomitant medication. The following cough symptoms were evaluated: cough intensity, cough frequency and extent of coughing periods per day. Coughing intensity and frequency as well as cough-dependent symptoms were strongly reduced after three days. Two adverse events occurred in the 0-3 age group which were not attributed to the drug. Tolerability of marshmallow root was reported as very good [Fasse 2005].

Pharmacokinetic properties
No data available.

Preclinical safety data
No data available.

Clinical safety data
A total of 373 adults and children with cough were treated with various doses of marshmallow root in 2 clinical studies. In thirty patients treated with 3 x 40 mg/d marshmallow root for 4 weeks, adverse events were not reported [Rouhi 2007]. In the study with 313 children that received a marshmallow root

containing syrup (Phytohustil®, DER 1:20), for 3 days or more, one adverse event (development of obstructive bronchitis) and one serious adverse event (development of bronchopneumonia resulting in hospitalisation) occurred in the 0-3 years age group, but these were not attributed directly to the drug. The tolerability of marshmallow root was reported as very good [Fasse 2005].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ANGELICAE RADIX

2021

Angelica Root

DEFINITION

Angelica root consists of the whole or cut, carefully dried rhizome and root of *Angelica archangelica* L. (syn. *A. officinalis* Hoffm.). It contains not less than 2.0 mL/kg of essential oil, calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Angelica root].

CONSTITUENTS

The main characteristic constituents are:

Essential oil (0.2-1%) of variable composition, consisting mainly of monoterpenes, such as α-pinene, δ-3-carene, β-phellandrene, sabinene, limonene, *p*-cymene and myrcene, together with small amounts of sesquiterpenes, such as α-copaene, germacrene D, β-bisabolene and caryophyllenes and macrocyclic lactones [Taskinen 1975; Kerrola 1994; Lawrence 1989; Lawrence 1996; Chalchat 1997; Wedge 2009].

Coumarins, principally the prenylcoumarins, osthenol (0.04%) and osthole. Furanocoumarins including auraptene, bergapten, angelicin, imperatorin, isoimperatorin, oxypeucedanin, oxypeucedanin hydrate, 7-isopentenyl-oxycoumarin, phellopterin, ostruthol, byakangelicin angelate, xanthotoxin, umbelliprenin, psoralen and isopimpinellin, and the dihydrofuranocoumarins archangelicin and 2′-angeloyl-3′-isovaleryl vaginate [Genius 1981; Härmälä 1992a,b; Roos 1997; Eeva 2004; Taddeo 2017].

Other constituents include phenolic acids (chlorogenic and caffeic acids, 4′-geranyloxyferulic acid), sitosteryl esters, angelic acid and various fatty acids, tannins and starch [Baerheim Svendsen 1951; Eichstedt 1963; Czygan 1998; Taddeo 2017].

CLINICAL PARTICULARS

Therapeutic indications

Dyspeptic complaints such as mild gastrointestinal spasms, sluggish digestion, flatulence and feeling of fullness, loss of appetite, bronchitis [Ożarowski 1987; Bruneton 1995; Vieweger 1998; Chevallier 2001; Sarker 2004; Bradley 2006, Stahl-Biskup 2016].

Efficacy in these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adult daily dose: 3-6 g of the drug, or as an infusion; liquid extract 1:1 in 25% ethanol, 1.5-6 ml; tincture 1:5 in 50% ethanol, 1.5-6 ml, preferably divided into three doses [Todd 1967; Angelica root 1983; Bradley 2006; Stahl-Biskup 2016].

Elderly: dose as for adults.

Children over 4 years, average daily dose: 4-10 years of age, 2-3 g; *10-16 years of age*, 3-4 g [Dorsch 2002].

Method of administration
For oral administration.

Duration of administration
No restriction.

E/S/C/O/P
MONOGRAPHS

Contra-indications
None known.

Special warnings and special precautions for use
Care should be taken concerning prolonged exposure to sunlight while taking angelica root preparations since skin photosensitization due to the presence of furocoumarins was deduced from preclinical studies with the essential oil [Søborg 1996;Tisserand 2014].

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Spasmolytic activity
Significant spasmolytic activity was exerted by a 50% methanolic extract on isolated guinea pig ileum ($p<0.05$ to $p<0.01$). Spontaneous contractions of the circular smooth muscle were inhibited with an IC_{50} of 265 µg/mL compared to 3.94 µg/mL for papaverine. Acetylcholine- and barium chloride-induced contractions of the longitudinal smooth muscle were reduced with IC_{50} values of 242 and 146 µg/mL, respectively, compared to 4.82 and 4.90 µg/mL for papaverine [Izzo 1996].

The essential oil inhibited contractions of isolated guinea pig tracheal and ileal smooth muscle with IC_{50} values of 2.5 µg/mL and 10 µg/mL respectively [Reiter 1985].

Angelicin at 20 µg/mL produced marked relaxation of isolated rabbit duodenum and 50% inhibition of acetylcholine-, histamine- and barium chloride-induced contractions of isolated guinea pig ileum [Chandhoke 1975].

Calcium-blocking activity
Depolarization-induced uptake of $^{45}Ca^{2+}$ ions into cultured rat pituitary GH_4C_1 cells was inhibited by extracts of angelica root [Härmälä 1992b]. The effect was attributed to coumarins and furanocoumarins; osthole, imperatorin, isoimperatorin and phellopterin gave IC_{50} values in the range of 4-12 µg/mL [Härmälä 1992a]. A methanolic extract (not further specified) and archangelicin had IC_{50} values of 3.9 µg/mL and 1.2 µg/mL respectively, compared to verapamil (IC_{50} 2.0 µg/mL) [Härmälä 1991, 1992a, 1992b, Vuorela 1997].

Anti-inflammatory activity
A dry extract (24:1, petroleum ether-dichloromethane 1:1) at 50 µg/mL inhibited microsomal COX-1 from sheep seminal vesicles by 55% and 5-LOX in porcine leucocytes by 85%. In similar assays, coumarins showed no inhibitory activity on COX-1; however, osthole and oxypeucedanin hydrate isovalerate concentration-dependently inhibited 5-LOX with IC_{50} values of 36.2 and 127.5 µM, compared to 36.3% inhibition by nifedipine at 100 µM [Roos 1997].

An essential oil (α-pinene 21.3%, β-3-carene 16.5%, limonene 16.4%) significantly ($p<0.05$) reduced IL-6 release in LPS-stimulated human umbilical vein endothelial cells at 73 µg/mL [Fraternale 2018].

Antimicrobial activity
An essential oil (α-pinene 28.7%, β-3-carene 14.2%) exhibited MIC values of 14.2 µL/mL and 28.4 µL/mL against *S. aureus* and *E. coli* respectively, while the MBC values were 56.8 µL/mL and 113.6 µL/mL respectively. Gentamicin as a positive control showed MIC/MBC values of 0.25/0.75 µg/mL for *S. aureus* and 0.5/0.1 µg/mL for *E. coli* respectively [Aćimović 2017].

Antiviral activity
A dichloromethane extract (12:1) and isolated compounds such as imperatorin, phellopterin, isoimperatorin and bergapterin, as well as the mixture of imperatorin and phellopterin, were investigated in the virus titre reduction assay against *Herpes simplex* virus-1 (HSV-1) and Coxsackievirus B3 (CVB3). The extract, imperatorin, phellopterin and the mixture reduced the HSV-1 titre (expressed as $TCID_{50}$/mL) significantly ($p<0.05$) while the activity on CVB3 replication was not significant [Rajtar 2017].

Cytotoxic activity
Various furanocoumarins inhibited cell proliferation of HeLa S3 cells at 25 µg/mL; the order of potency was osthole > isopimpinellin > bergapten > xanthotoxin > imperatorin. Xanthotoxin and imperatorin also inhibited the proliferation of lymphocytes *in vitro*, and xanthotoxin inhibited the growth of tumours induced in mice (Ehrlich carcinoma) and rats (sarcoma 45) [Gawron 1987].

A 65% ethanolic extract (not further specified) was cytotoxic to human breast cancer cells MCF-7 and mouse mammary carcinoma cells 4T1 at 250 µg/mL and inhibited 50% of cell viability ($p<0.001$). No toxicity was observed in normal CCD1072Sk fibroblasts [Oliveira 2019].

An essential oil (α-pinene 21.3%, β-3-carene 16.5%) at more than 200 µg/mL induced apoptosis and to a lesser extent necrosis in U937 lymphoma cells after 4 hours of treatment ($p<0.05$). With 150 µg/mL only approximately 50% apoptosis and no necrosis were observed [Fraternale 2018].

Other effects
A hexane extract inhibited butyrylcholinesterase (BChE) with an IC_{50} of 16 ±5 µg/mL. Imperatorin showed IC_{50} values of 14.4±3.2 µg/mL (BChE) and 156±15 µg/mL (acetylcholinesterase, AChE). The IC_{50} for heraclenol-2'-O-angelate was 7.5±1.8 µg/mL for BChE as compared to physostigmine (1.73±0.4 µg/mL for BChE and 0.21±0.1µg/mL for AChE) and to galanthamine (8.3±2.6 µg/mL for BChE and 0.37±1.1 µg/mL for AChE) [Wszelaki 2011].

Chloroform and methanolic extracts (not further specified), the combination of these extracts, as well as osthole, were tested for their ability to inhibit ketohexokinase isoform C (KHKC) activity. The chloroform extract and the combination showed KHKC inhibition with IC_{50} values of 57.3 and 30.3 µg/mL respectively. The IC_{50} value for osthole was 0.7 µg/mL [Le 2016].

An aqueous methanolic extract (not further specified) inhibited urease with an IC_{50} of 64.03 µg/mL [Biglar 2014].

Phellopterin strongly inhibited the binding of [^{3}H]diazepam to CNS benzodiazepine receptors in isolated rat cortical membrane with an IC_{50} of 0.36 µM as compared to diazepam (IC_{50}: 0.018 µM). The selectivity of the benzodiazepine receptor for phellopterin was much greater than for various structurally similar furanocoumarins [Bergendorff 1997].

In vivo experiments

Gastro-intestinal effects
An ethanolic liquid extract (osthenol 53 µg/mL), administered orally to rats at 2.5-10 mL/kg b.w. one hour before the oral administration of indomethacin (10 mg/kg b.w.), reduced the ulcer index by 35-45%. This was associated with reduced acidity of the gastric juice, increased mucin secretion and prostaglandin E_2 release, and a decrease in leukotrienes (all $p<0.05$ compared to indomethacin). The anti-ulcerogenic effect of the extract was confirmed histologically [Khayyal 2001].

Hepatoprotective effects
Mice with ethanol-induced hepatotoxicity were treated orally with a dry aqueous extract at 10, 25 and 50 mg/kg three times per week for 4 weeks. The extract significantly ($p<0.05$) reduced both serum GOT and GTP levels and significantly ($p<0.05$) and dose-dependently inhibited malondialdehyde formation in mouse liver homogenates [Yeh 2003].

Anti-inflammatory and analgesic effects
Osthole inhibited carrageenan-induced rat paw oedema by 61.8% at 500 mg/kg b.w. p.o. and by 65.3% at 50 mg/kg i.p. ($p<0.01$), compared to 47.2% for indomethacin (10 mg/kg b.w. i.p.). Osthole inhibited acetic acid-induced writhing in mice by 53.9% at 250 mg/kg b.w. p.o. and by 61.2% at 50 mg/kg b.w. s.c. ($p<0.01$) compared to 69.7% for acetylsalicylic acid at 100 mg/kg b.w. s.c. [Kosuge 1985].

Sedative activity
Angelicin exhibited potent sedative, anticonvulsant and central muscle relaxant activity in mice, rats and rabbits. When administered p.o. to rats at 40-300 mg/kg or i.p. at 20-80 mg/kg b.w. it caused marked sedation, flaccidity, inhibition of spontaneous motor activity (77% at 80 mg/kg i.p.) and hypothermia. The ED_{50} for most of the parameters in rats was 30-40 mg/kg b.w. p.o. and 6-15 mg/kg b.w. i.p. [Chandhoke 1975].

Anxiolytic effects
A 95% methanolic extract (not further specified) was evaluated in albino rats using the elevated plus maze test. The rats were treated with diazepam (1 mg/kg b.w.) or doses of 200 mg/kg and 400 mg/kg b.w. of the extract. At the higher dose, the extract significantly ($p<0.05$) increased the number of entries and the duration of time spent in the open arms while both parameters decreased in the closed arms [Kumar 2012].

In the elevated plus-maze test, light and dark-box and whole board-box, the anxiety-like behaviour of albino rats was investigated using diazepam (1 mg/kg b.w.), imperatorin (5 mg/kg b.w.), isoimperatorin (5 mg/kg b.w.) or vehicle only. One hour after administration all substances showed significant activity ($p<0.05$, $p<0.01$) on the anxiety-like behaviour [Kumar 2013].

Anticonvulsant effects
An essential oil (not further specified) was evaluated against electrically- and chemically-induced seizures as well as in the rota-test. In maximal electroshock-induced seizures in mice, 30 min after i.p. administration of either vehicle (10 mL/kg b.w.), the essential oil (50, 100, 200, 400, 500 mg/kg b.w.) or phenytoin sodium (25 mg/kg b.w.), only the oil at 500 mg/kg b.w. and phenytoin resulted in a 100% protection against the tonic hind limb extensor phase. In pentylenetetrazol-induced seizures, the highest dose of the essential oil resulted in significant reduction of mortality, postponed the onset of general clonus ($p<0.05$) and decreased the duration of clonus compared to vehicle. In the rota-test, the essential oil at a dose of 500 mg/kg b.w. had a significant ($p<0.05$) influence on the motor function [Pathak 2010].

Imperatorin, osthole and valproate (positive control) were tested in maximal electroshock (MES)-induced seizures and chimney tests in mice. The animals were treated (i.p.) at 15, 30, 60 and 120 min before the test. The ED_{50} values for imperatorin were in the range of 185-290 mg/kg b.w., for osthole 266-639 mg/kg b.w. and for valproate 189-255 mg/kg b.w., depending on the timing of pre-treatment. In the chimney test, acute adverse effects on motor coordination were seen with TD_{50} values of 329-433 mg/kg b.w. for imperatorin, 531-648 mg/kg b.w. for osthole and 363-512 mg/kg b.w. for valproate. Imperatorin exhibited greater anticonvulsant activity than osthole while osthole demonstrated less acute neurotoxic effects than imperatorin, both in relation to valproate [Luszczki 2009].

Antitumour activity
A 65% ethanolic extract (not further specified) significantly ($p<0.05$) reduced tumour growth and tumour weight when administered by gavage at a dose of 500 mg/kg b.w. to mice inoculated with 4T1 cells as compared to the untreated group [Oliveira 2019].

Clinical studies
None published.

Pharmacokinetic properties
No data available.

Preclinical safety data
Angelica root is accepted as a food flavouring by the Council of Europe [Angelica archangelica 2000] and is generally recognized as safe (GRAS) in the USA [Anonymus 2018].

Angelica root oil has been assessed as non-toxic (i.e. safe for oral use at therapeutic dose levels), very mildly irritant and non-sensitizing, but phototoxic if applied in concentrations greater than 0.78% to areas of skin exposed to sunshine [Tisserand 2014].

Acute toxicity
The oral LD_{50} of angelica root oil was determined as 2.2 g/kg b.w. in mice and 11.2 g/kg b.w. in rats [Opdyke 1975].

An extract (not further specified) administered orally to rats at a dose of 3200 mg/kg b.w. was found to be safe [Kumar 2012].

Oral doses of 20 mg/kg b.w. imperatorin as well as isoimperatorin were determined as safe in rats [Kumar 2013]. The oral LD_{50} of angelicin in rats was found to be 321.6 mg/kg b.w. [Chandhoke 1975].

Subchronic toxicity
When angelica root oil was administered to rats for 8 weeks, the tolerated dose was concluded to be 1.5 g/kg b.w. [Opdyke 1975].

Mutagenicity
A tincture and a liquid extract showed weak mutagenic potential in the Ames test using *Salmonella typhimurium* strains TA 98 and TA 100 [Göggelmann 1986].

In the micronucleus test in murine bone marrow cells, aqueous and alcoholic extracts exhibited antimutagenic activity against triethylenethiophosphoramide (thio-TEPA)-induced

mutagenicity. The reduction of micronucleus frequencies was more marked when the extracts were injected 2 hours before thio-TEPA treatment. No genotoxic effects of the extracts were observed at concentrations of 50-100 mg/kg [Salikhova 1993, 1995].

Clinical safety data
No clinical data available for mono-preparations.

Data from clinical studies and post-marketing surveillance studies involving a total of over 5000 patients, as well as from adverse event reporting systems, showed that angelica root was safe when used as a herbal combination in which 10% by volume is angelica root tincture (1:3, ethanol 30% V/V) [Saller 2002].

Data from randomized, controlled studies (413 patients), prospective non-interventional studies (5,795 patients) and more than 40,000 children in retrospective database surveillances, showed that angelica root was safe when used as a herbal combination in which 10% by volume is angelica root extract (1-2.5-3.5, ethanol 30% V/V) [Ottillinger 2013].

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ANISI FRUCTUS

2014

Aniseed

DEFINITION

Aniseed consists of the whole dry cremocarp of *Pimpinella anisum* L. It contains not less than 20 ml/kg of essential oil.

The material complies with the monograph of the European Pharmacopoeia [Aniseed].

Note: In The European Pharmacopoeia (Eds 1,2 and 3), the monograph for Anise Oil permits oils obtained by steam distillation from the fruits of *Pimpinella anisum* L. (aniseed) or *Illicium verum* L. (star anise). *Trans*-anethole is the predominant component of both oils, but the other components are not identical. The term 'anise oil' is therefore avoided in the following text and the terms 'essential oil' or 'oil' refer specifically to the essential oil from aniseed.

CONSTITUENTS

The essential oil (2-6%) contains predominantly *trans*-anethole (80-95%) with smaller amounts of estragole, *cis*-anethole, anisaldehyde and pseudoisoeugenyl-2-methylbutyrate [Blaschek 2007; Kubeczka 1976; Kubeczka 1978; Schultze 1987]; sesquiterpene and monoterpene hydrocarbons are also present [Kubeczka 1976; Scultze1987; Orav 2008].

Other constituents include flavonol glycosides [El-Moghazi 1979; Kunzemann 1977], phenolic acids [Schulz 1980; Baerheim-Svendsen 1951; El-Wakeil 1986], phenolic and hydroxyalkylglucosides [Dirks 1984; Fujimatu 2003] furanocoumarins [Ceska 1987; Kartnig 1969], hydroxycoumarins [Blaschek 2007] and fatty oil [Kartnig 1969].

CLINICAL PARTICULARS

Therapeutic indications
Dyspeptic complaints and mild spasmodic gastro-intestinal complaints, such as bloating, flatulence [Blaschek 2007; Czygan 2002; Weiss 1997; Pimpinella 1983; Sweetman 2011; Czygan 1992; Hänsel 1999].

In mild inflammation of the upper respiratory tract, as expectorant [Blaschek 2007; Czygan 2002; Weiss 1997; Pimpinella 1983; Sweetman 2011; Czygan 1992; Hänsel 1999].

In these indications the effects are plausible on the basis of human experience and longstanding use.

Posology and method of administration

Dosage

Adult average daily dose: 3 g of crushed fruits as an infusion or similar preparation [Czygan 2002; Pimpinella 1983].

Children, average daily dose: *0-1 year of age*, 0.5 g of crushed fruits as an infusion; *1-4 years of age*, 1 g; *4-10 years of age*, 2 g; *10-16 years of age*, the adult dose [Dorsch 2002].

Method of administration
For oral administration.

Duration of use
No restriction.

If symptoms persist, consult your doctor.

Contra-indications
Persons with known sensitivity to anethole should avoid aniseed.

E/S/C/O/P MONOGRAPHS

Special warnings and special precautions for use
Persons with known sensitivity to anethole should avoid aniseed [Newall 2002; Andersen 1978; Franks 1998]. The sensitizing potential of aniseed is considered low [Hausen 1988].

Interaction with other medicaments and other forms of interaction
None known. Experimental data on weak enzyme induction in rodents cannot be directly extrapolated to man [Marcus 1982].

Pregnancy and lactation
Aniseed may be used during pregnancy and lactation at the recommended dosage, as aqueous infusions only.

Preparations containing the essential oil [Tisserand 1995] or alcoholic extracts should not be used during pregnancy and lactation. Mild oestrogenic activity and antifertility effects of the essential oil and anethole (the major constituent of the essential oil) have been demonstrated *in vitro* and in rats [Dhar 1995].

Effects on ability to drive and use machines
None known.

Undesirable effects
Rare cases of contact dermatitis caused by anethole-containing toothpastes and cosmetic creams [Barnes 2007; Andersen 1978], occupational rhinoconjunctivitis and food allergy caused by working in a bakery making biscuits with aniseed [Garcia-Gonzales 2002] and repeated episodes of tongue angioedema in a patient after drinking aniseed liqueur [Garcia 2007].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties
The medicinal use of aniseed is largely due to secretolytic, antispasmodic and secretomotor effects of its essential oil [Blaschek 2007].

In vitro experiments

Antimicrobial effects
An acetone extract of aniseed inhibited the growth of a range of bacteria including *Escherichia coli* and *Staphylococcus aureus*, and also exhibited antifungal activity against *Candida albicans* and other organisms [Gülcin 2003; Maruzella 1959].

Essential oil of aniseed inhibited the growth of *Escherichia coli* (MIC: 0.5% V/V), *Staphylococcus aureus* (MIC: 0.25%), *Salmonella typhimurium* (MIC: 2.0%) and *Candida albicans* (MIC: 0.5%) using the agar dilution method [Hammer 1999]. Antimicrobial activity of the oil has also been demonstrated in other studies [Ramadan 1972; Shukla 1987; Ibrahim 1991].

A methanolic dry extract of aniseed reduced the resistance of *Pseudomonas aeruginosa* to certain antibiotics when used in combination with the individual antibiotic (both the extract and antibiotic being at concentrations which did not inhibit growth when used alone; antibiotic concentrations were half their minimum inhibitory concentrations). The aniseed extract was particularly effective in combination with chloramphenicol, gentamicin, cephalexin, tetracycline or nalidixic acid against the standard strain of *P. aeruginosa*, causing almost complete inhibition of growth; it was less effective against a particularly resistant strain of *P. aeruginosa*, but inhibited growth by 74% in combination with tetracycline [Aburjai 2001].

The essential oil (0.0125-0.1%) concentration-dependently inhibited the growth of the fungi *Aspergillus flavus, A. parasiticus, A. ochraceus* and *Fusarium moniliforme*. The formation of mycotoxins (aflatoxins, ochratoxin A and fumonisin) in wheat infected with the fungi were also inhibited [Soliman 2002].

Secretolytic and expectorant effects
A modest increase in mucociliary transport velocity of isolated ciliated epithelium from the frog oesophagus was observed 90 seconds after application of 200 µl of an infusion from aniseed (4.6 g per 100 mL of water) [Müller-Limroth 1980].

Spasmolytic effects
The essential oil at 200 mg/litre produced complete relaxation of carbachol-induced contractions of isolated tracheal smooth muscle from the guinea pig. In contrast, the oil increased the contraction force in electrically-stimulated guinea pig ileal smooth muscle with an EC_{50} of 6-7 mg/litre (a positive inotropic effect) [Reiter 1985].

The essential oil (0.02 mL), an aqueous extract (0.6 mL, equivalent to 1.5 g of aniseed) and an ethanolic extract (0.1 mL, equivalent to 0.25 g of aniseed) exhibited relaxant effects on methacholine-induced contractions of guinea pig tracheal chains (prepared from rings of isolated tracheal smooth muscle). The bronchodilatory effects were significant ($p<0.05$, $p<0.005$, $p<0.001$ respectively) compared to those of controls (0.6 mL of saline for the essential oil and aqueous extract; 0.1 mL of ethanol for the ethanolic extract) [Boscabady 2001].

Local anaesthetic activity
Trans-anethole concentration-dependently reduced electrically-evoked contractions of rat phrenic nerve-hemidiaphragm, by 10.3% at 10^{-3} µg/mL, by 43.9% at 10^{-2} µg/mL, by 79.7% at 10^{-1} µg/mL and by 100% at 1 µg/mL [Ghelardini 2001].

Tumour-inhibiting activity
Anethole at a concentration below 1 mM has been shown to be a potent inhibitor of tumour necrosis factor (TNF)-induced cellular responses, such as activation of nuclear factor-kappa B (NF-κB) and other transcription factors, and also to block TNF-induced activation of the apoptotic pathway. This might explain the role of anethole in suppression of inflammation and carcinogenesis [Chainy 2000].

Oestrogenic activity
Dry extract of aniseed with hot water (DER 10:1) exhibited selective oestrogen receptor modulator (SERM)-like properties in various *in vitro* assays. At a concentration of 25 µg/mL, the extract caused a significant ($p<0.05$) increase in alkaline phosphatase activity. At 50 µg/mL it significantly ($p<0.05$) increased the formation of mineralized nodules [Kassi 2004].

The essential oil, and the pure isolated compound *trans*-anethol, exhibited extremely weak oestrogenic effect using the yeast oestrogen screen (YES) assay (yeast cells expressing the human oestrogen receptor) with an EC_{50} of 600 µg/mL for the essential oil and 625 µg/mL for *trans*-anethol. Relative potency compared to 17β-estradiol was 9.47×10^{-8} for the essential oil and 8.6×10^{-8} for trans-anethol [Tabanca 2004].

Using the same model, the potency of 17β-estradiol was found to be at least 10^5-10^6 times that of anethole, as well as for the other essential oil constituents [Howes 2002].

Antioxidant activity
The essential oil in concentrations of 2µM and 5µM inhibited the copper-catalyzed oxidation of human LDL by 40% and 71% respectively [Teissedre 2000]. An aqueous dry extract of

aniseed exhibited antioxidant activity in six different *in vitro* assays [Hinneburg 2006].

In vivo experiments

Secretolytic and expectorant effects
An emulsion of 2 drops of the essential oil, administered intragastrically to cats, caused hypersecretion of mucus in the air passages and stimulated ciliary removal of mucus (which had been inhibited by opium alkaloids) [VanDongen 1953].
A solution of the essential oil in 12% ethanol, administered intragastrically to anaesthetised guinea pigs at 50 mg/kg b.w., induced a 3- to 6-fold increase in respiratory tract fluid during the first 2 hours after administration; even 10 mg/kg caused a 2-fold increase [Boyd 1946]. A similar experiment in anaesthetised rats, dosed orally with the oil at 0.0015 mL/kg, resulted in a 28% increase of respiratory tract fluid without influencing chloride concentration or density [Boyd 1954]. Administration of the oil vapour to anaesthetised rabbits by inhalation (in steam) dose-dependently increased the volume of respiratory secretion by 19-82%; doses added to the vaporizer were 0.7-6.5 g/kg b.w. (the amount to which the animals were exposed being considerably less). However, at the highest dose level there were signs of tissue damage and a mortality rate of 20% [Boyd 1968].

Sedative effect
The pentobarbital-induced sleeping time of mice was prolonged by 93.5% ($p<0.01$) after simultaneous intraperitoneal administration of essential oil at 50 mg/kg b.w.; *trans*-anethole gave similar results [Marcus 1982].

Anticonvulsant effect
The anticonvulsant effect of intraperitoneally administered aniseed oil in mice with seizures induced by pentylenetetrazole (PTZ) and maximal electroshock (MES) was investigated. Pretreatment with the oil significantly ($p< 0.001$) suppressed PTZ-induced hind limb tonic extensions (HLTE) and mortality with an ED_{50} value of 0.52 mL/kg b.w., and MES-induced HLTE and mortality with an ED_{50} value of 0.20 mL/kg b.w. ($p<0.001$). The essential oil dose-dependently increased the dose of i.v. administered PTZ needed to induce seizures in the mice ($p<0.01$ for 1 mL oil/kg b.w.) [Pourgholami 1999].

Oestrogenic activity
Trans-anethole administered orally to immature female rats at 80 mg/kg b.w. for 3 days significantly increased uterine weight, to 2 g/kg compared to 0.5 g/kg in controls and 3 g/kg in animals given oestradiol valerate subcutaneously at 0.1 µg/rat/day ($p<0.001$). The results confirmed that *trans*-anethole had oestrogenic activity; other experiments showed that it has no anti-oestrogenic, progestational, anti-progestational, androgenic or anti-androgenic activity [Dhar 1995].

Local anaesthetic activity
In the rabbit conjunctival reflex test, solutions of *trans*-anethole administered into the conjunctival sac concentration-dependently increased the number of stimuli required to evoke the conjunctival reflex ($p<0.01$): 9.7 stimuli at 10 µg/mL, 31.8 stimuli at 30 µg/mL and 65.2 stimuli at 100 µg/mL, compared to about 3 stimuli for vehicle controls. The effect was comparable to that of procaine [Ghelardini 2001].

Anti-tumour activity
In Swiss albino mice with Ehrlich ascites tumour (EAT) in the paw, anethole administered orally at 500 or 1000 mg/kg on alternate days for 60 days significantly and dose-dependently reduced tumour weight ($p<0.05$ at 500 mg/kg, $p<0.01$ at 1000 mg/kg), tumour volume ($p<0.01$ at 500 mg/kg, $p<0.001$ at 1000 mg/kg) and body weight ($p<0.05$ to 0.01) compared to EAT-bearing controls. Mean survival time increased from 54.6 days to 62.2 days (500 mg/kg) and 71.2 days (1000 mg/kg). Histopathological changes were comparable to those after treatment with cyclophosphamide (a standard cytotoxic drug). These and other results demonstrated the anticarcinogenic, cytotoxic and non-clastogenic nature of anethole [Al-Harbi 1995].

Anti-ulcer activity
An aqueous suspension of aniseed, administered to rats intragastrically at a dose equivalent to 250 and 500 mg crude drug/kg b.w., significantly ($p<0.001$) prevented gastric mucosal lesions induced by 80% ethanol, 0.2M NaOH or 25%NaCl [Al Mofleh 2007].

Enzyme induction
Subcutaneous administration of the essential oil to partially (two-thirds) hepatectomized rats at 100 mg/animal/day for 7 days stimulated liver regeneration ($p<0.01$) [Gershbein 1977].

Experiments in which rats were injected intraperitoneally with a mixture of *trans*-anethole (100 mg/kg b.w.) and [14C] parathion (1.5 mg/kg) showed no significant effect of *trans*-anethole on metabolism and excretion of the insecticide. However, when rats were fed a diet containing 1% of *trans*-anethole for 7 days and subsequently cell fractions from the livers of these rats were incubated for 2 hours with [14C] parathion, significantly less unchanged parathion (1.6%) was recovered compared to controls (12.5%). The data were interpreted as suggesting that feeding *trans*-anethole to rats for 7 days induced the synthesis of parathion-degrading liver enzymes [Marcus 1982].

Anti-diuretic activity
Aniseed oil, added to drinking water at a 0.05% concentration, exerted a significant ($p<0.027$) anti-diuretic effect in rats, as expressed by the urine to water intake ratio [Kreydiyyeh 2003].

Pharmacokinetic properties

Pharmacokinetics in animals
No data available for aniseed.

In mice and rats *trans*-anethole is reported to be metabolized by O-demethylation and by oxidative transformation of the C3-side chain. After low doses (0.05 and 5 mg/kg b.w.) O-demethylation occurs predominantly, whereas higher doses (up to 1500 mg/kg b.w.) give rise to higher yields of oxygenated metabolites [Sangster 1984a; Sangster 1984b].

Pharmacokinetics in humans
No data available for aniseed.

After oral administration of radioactively-labelled *trans*-anethole (as the *methoxy*-^{14}C compound) to 5 healthy volunteers at dose levels of 1, 50 and 250 mg on separate occasions, it was rapidly absorbed. 54-69% of the dose (detected as ^{14}C) was eliminated in the urine and 13-17% in exhaled carbon dioxide; none was detected in the faeces. The bulk of elimination occurred within 8 hours and, irrespective of the dose level, the principal metabolite (more than 90% of urinary ^{14}C) was 4-methoxyhippuric acid [Caldwell 1988]. An earlier study with 2 healthy subjects taking 1 mg of *trans*-anethole gave similar results [Sangster 1987].

Preclinical safety data
Most toxicity studies relevant to aniseed have been conducted on *trans*-anethole, the major constituent of the essential oil.

Acute toxicity
Oral LD_{50} values per kg b.w. have been determined for the

essential oil as 2.7 g in rats [Sangster 1987] and for *trans*-anethole as 1.82-5.0 g in mice, 2.1-3.2 g in rats and 2.16 g in guinea pigs [Lin 1991].

Intraperitoneal LD_{50} value for the essential oil from aniseed was determined as 0.93 (1.11-0.79) mL/kg bw. for mice [Pourgholami 1999].

Intraperitoneal LD_{50} values for *trans*-anethole have been determined as 0.65-1.41 g/kg in mice and 0.9-2.67 g/kg in rats [Lin 1991].

Repeated-dose toxicity
No data available for aniseed.

In 90-day experiments in rats, 0.1% of *trans*-anethole in their diet caused no toxic effects. However, dose-related oedema of the liver was reported at higher levels of 0.3%, 1% and 3%, which have no therapeutic value [Lin 1991]. Male rats receiving 0.25% of anethole in their diet for 1 year showed no toxic effects, while others receiving 1% for 15 weeks had slight oedematous changes in liver cells [Hagan 1967]. Rats given *trans*-anethole as 0.2, 0.5, 1 or 2% of their diet for 12-22 months showed no effects at any level on clinical chemistry, haematology, histopathology or mortality. Slower weight gain and reduced fat storage were noted at the 1% and 2% levels [Lin 1991, LeBourhis 1973].

Reproductive toxicity
Trans-anethole exerted dose-dependent anti-implantation activity after oral administration to adult female rats on days 1-10 of pregnancy. Compared to control animals (all of which delivered normal offspring on completion of term), *trans*-anethole administered at 50, 70 and 80 mg/kg b.w. inhibited implantation by 33%, 66% and 100% respectively. Further experiments at the 80 mg/kg dose level showed that in rats given *trans*-anethole only on days 1-2 of pregnancy normal implantation and delivery occurred; in those given *trans*-anethole only on days 3-5 implantation was completely inhibited; and in those given *trans*-anethole only on days 6-10 three out of five rats failed to deliver at term. No gross malformations of offspring were observed in any of the groups. The results demonstrated that *trans*-anethole has antifertility activity. From comparison with the days 1-2 group (lack of antizygotic activity), the lower level of delivery in the days 6-10 group was interpreted as a sign of early abortifacient activity [Dhar 1995].

Mutagenicity
A dry ethanolic aniseed extract was mutagenic at high concentrations (5 mg/plate) to streptomycin-dependent strains of *Salmonella typhimurium* TA 98 [Shashikanth 1986]. An ethanolic aniseed extract gave negative results at the maximum non-toxic concentration of 0.1 mg/mL in chromosomal aberration tests using a Chinese hamster 1984 cell line [Ishidate].

The essential oil and *trans*-anethole were mutagenic at 2 mg/plate in the Ames test using *Salmonella typhimurium* strains TA 98 and TA 100, and mutagenicity was potentiated by S13 activation [Marcus 1982]. In another study, *trans*-anethole was mutagenic to *Salmonella typhimurium* TA 100 in the Ames test with S9 activation, doses of 30-120 µg/plate showing a dose-dependent increase in revertants, which did not exceed twice the number of the control [Sekizawa 1982]. Other investigations with metabolic activation have confirmed that *trans*-anethole is weakly mutagenic [Lin 1991].

Estragole, a minor constituent of anise oil, has also shown mutagenic potential in various Ames tests, demonstrating the need for carcinogenicity studies [DeVincenzi 2000; European commission 2001].

Anti-genotoxic activity of trans-anethole
In the mouse bone marrow micronucleus test, oral pre-treatment of mice with trans-anethole at 40-400 mg/kg b.w., 2 and 20 hours before intraperitoneal injection of genotoxins, led to moderate, dose-dependent protective effects against known genotoxins such as cyclophosphamide, procarbazine, N-methyl-N'-nitrosoguanidine, urethane and ethyl methane sulfonate ($p<0.05$ to $p<0.01$ at various dose levels). No significant increase in genotoxicity was observed when *trans*-anethole (40-400 mg/kg b.w.) was administered alone [Abraham 2001].

Carcinogenicity
A 1-year experiment in which mice received *trans*-anethole in their diet gave no evidence of carcinogenic potential: low levels of DNA adducts were observed in liver tissue [Lin 1991]. In another chronic study of *trans*-anethole in mice there were no histological differences between treated and control animals [Miller 1983]. In a study in rats, the highest dose feeding group (1% *trans*-anethole for 117 weeks) presented with hyperplastic and partially neoplastic changes in the livers of female (but not male) rats; a review of these results confirmed that the observed neoplastic changes in the liver were not due to a direct genotoxic effect induced by *trans*-anethole [Lin 1991].

Genotoxicity studies performed with aniseed extracts, the essential oil, *trans*-anethole and estragole do not provide adequate data to fully evaluate the carcinogenic risk. However, the carcinogenic risk from aniseed in man is assumed to be low [Aniseed].

Clinical safety data
A severe case of poisoning with anise oil after intake of 10-15 ml oil is reported. The symptoms were convulsions, unconsciousness and vomiting [Bang 2008].

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ARCTII RADIX

Burdock root

DEFINITION

Burdock root consists of dried, whole or cut roots of *Arctium lappa* L. (= *A. major* Gaertn.), *A. minus* (Hill) Bernh., *A. tomentosum* Mill. and hybrids or mixtures thereof. The root is collected in the autumn of the first year or in the spring of the second year. The material complies with DAC 2014 or with the French Pharmacopoeia [Ph. Fr, 1989].

CONSTITUENTS

The main characteristic constituents are:

- Carbohydrates (ca. 70%) containing up to 45% of inulin [Wichtl 2009; Yotchkova 1990] in *A. lappa,* up to 27% in *A. minus* and up to 19% in *A. tomentosum* [De Smet 1993], a xyloglucane [Kato 1993]; 6.8% starch [Pandey 2007] and other fructans [Olennikov 2011], fructooligosaccharides with degrees of polymerization between 3 and 9 [Li 2013]. A fructan composed of fructose and glucose in the ratio of 13.0:1.0 [Liu 2014].

- Essential oil (0.06 to 0.2%) which contains mainly aplotaxene, dehydrocostuslactone, 11,13-dihydrodehydrocostuslactone and costic acid. Other components are aliphatic hydrocarbons, aliphatic and aromatic aldehydes, carbonic acids, pyrazines and sesquiterpenes [Washino 1985; Yotchkova 1990; Blaschek 2006].

- Polyacetylenic compounds (0.001 to 0.002%), the main one is trideca-1,11-diene-3,5,7,9-tetrayne, sulfur-containing acetylenic compounds (arctic acid, arctinone-a and -b, arctinol-a and -b, arctinal) [Washino 1986; Yotchkova 1990] and lappaphen-a and -b [Washino 1987].

- Phenolic acids (1.9 to 3.65%) [Wichtl 2003]: caffeic acid [Maruta 1995, Ferracane 2010, Liu 2012], hydroxycinnamoyl quinic acids [Lin 2008] such as chlorogenic acid [Pandey 2004 and 2007] and derivatives [Ferracane 2010, Jaiswal 2011; Haghi 2013] as well as tannins [Pandey 2007].

- Other constituents include triterpenes [Washino 1985, Yotchkova 1990], unsaturated sterols [Yotchkova 1990], arctigenin [De Souza Predes 2011, 2014] and arctiin [Ferracane 2010, Liu 2012] as well as b-asparagin [Boev 2005].

CLINICAL PARTICULARS

Therapeutic indications

Internal use
Seborrhoeic skin, eczema, furuncles, acne, psoriasis [Rolet and Bouret 1928; Planchon 1946; Fournier and Leclerc 1947; Paris and Moyse 1971; Valnet 1976; BHMA 1983; Van Hellemont and Delfosse 1986; Dorvault 1987; Rombi 1991; Bradley 1992; Cazin and Cazin 1997; Barnes 2007].

As an adjuvant in minor urinary tract complaints, by increasing the amount of urine to achieve flushing of the urinary tract [Rolet and Bouret 1928; Planchon 1946; Fournier and Leclerc 1947; Paris and Moyse 1971; Valnet 1976; BHMA 1976, 1983; Van Hellemont and Delfosse 1986; Dorvault 1987; Rombi 1991; Cazin and Cazin 1997; Barnes 2007].

External use
Seborrhoeic skin, eczema, furuncles, acne [Fournier et Leclerc 1947; Garnier 1961; Leclerc 1976; Paris et Moyse 1971; Valnet 1976; Van Hellemont and Delfosse 1986; Rombi 1991; Bradley 1992].

Efficacy in these indications is plausible on the basis of long-standing use.

E/S/C/O/P MONOGRAPHS

Posology and method of administration

Dosage

Internal use
Adult dose
At three times daily: 2 – 6 g as an infusion; 2 to 8 mL as a liquid extract (1:1, 25% ethanol); 8-12 mL as a tincture (1:10, 45% ethanol) [BHMA 1983, Bradley 1992, Barnes 2007].
As a decoction at 500 mL (1:20) per day [Barnes 2007].

External use:
Adults
Fresh pulp of root [Fournier et Leclerc 1947; Garnier 1961; Paris et Moyse 1971 ; Leclerc 1976].
Decoction (60 g/litre) [Garnier 1961; Leclerc 1976].

Method of administration
For oral administration and topical application.

Duration of use
If symptoms persist or worsen, medical advice should be sought.

Contra-indications
Hypersensitivity to plants of the Asteraceae family [Hausen 1997].

Special warnings and precautions for use
Burdock root should not be used in patients with oedema due to impaired heart and kidney function [Wichtl 2009].

Interaction with other medicinal products and other forms of interaction
None reported.

Pregnancy and lactation
The product should not be used during pregnancy and lactation [Barnes 2007].

Effects on ability to drive and use machines
None known.

Undesirable effects
Hypersensitivity can occur with topical application [Yotchkova 1990; Rodriguez 1995] or by oral route [Sasaki 2003].

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antibacterial activity
A dry ethanolic extract (1:5, 70%) demonstrated activity against *Bacillus subtilis* and several Gram negative bacteria (*E. coli*, *Shigella flexneri*, *Shigella sonnei*) but no activity against *Staphylococcus aureus* at 400 µg/disc [Moskalenko 1986].

Ethanolic extracts (70%; not further specified) demonstrated greater antimicrobial activity than dry water extracts (not further specified). MIC values for the ethanolic extracts were found to be 31.25 mg/mL for *Bacillus subtilis* and *Staphylococcus aureus*, 62.50 mg/mL for *Proteus vulgaris* and 250 mg/mL for *E. coli* [Mi 2010].

An extract (not further specified) at a concentration of 0.01% significantly inhibited the chemotaxis effect of *Propionibacterium acnes* on polymorphonuclear leucocytes ($p<0.05$) and exerted antibacterial activity against two strains of *P. acnes* with MICs of 1400 µg/mL, whereas the MICs for erythromycin were 300 and 0.5 µg/ml [Nam 2003].

A 25% ethanolic dry extract of *Arctium minus* exhibited greater than 60% inhibition of *S. aureus* at 40 µg/mL and more than 50% inhibition of *B. subtilis* at 200 µg/mL[Watkins 2012].

Antiviral properties
Epstein Barr virus activation induced by 40 ng 12-*O*-hexadecanoylphorbol-13-acetate and 88 µg of n-butyric acid was moderately inhibited at 50-69% by 40 µg of the ethylacetate soluble part of burdock root but not by 200 µg of a methanolic extract or 40 µg of a water soluble part (29% or less) [Koshimizu 1988].

When added to the medium at the time of viral infection and immediately after the viral infection, arctiin showed antiviral activity against influenza A virus (H1N1) with an IC_{50} of 24 and 22 µM respectively [Hayashi 2010].

Antioxidant activity
Ethanolic, aqueous and chloroform extracts showed activity in the DPPH radical scavenging test [Duh 1998, Dos Santos 2008, Chen 2009, Predes 2011, da Silva 2013].

Aqueous dry extracts showed antioxidant and radical scavenging effects in different test systems such as inhibition of linoleic acid peroxidation, inhibition of malondialdehyde formation, anti-$FeCl_2$ ascorbic acid-stimulated lipid peroxidation in rat liver homogenate, scavenging of superoxide, hydrogen peroxide and hydroxyl radical scavenging [Duh 1998].

A methanolic dry extract (10% m/V, DER not specified) showed significant antioxidant activity on liposome, deoxyribose, protein and LDL oxidation ($p<0.05$). In 3T3 cells, at 200 µg/mL, the extract enhanced GSH levels and increased significantly the activities of glutathione peroxidase, glutathione reductase, glutathione-*S*-transferase and catalase ($p< 0.05$). In RAW 264.7 cells stimulated with LPS, the extract scavenged NO in a dose-dependent manner and reduced COX-2 and iNOs protein expressions at 500 µg/mL [Wang 2006].

Elastase activity was inhibited by 50.9% by 10 mg/mL of an aqueous extract (no further details, approximately 0.1 mg/mL total phenolic content expressed as gallic acid). The antioxidant activity of the extract was equivalent to 4.73 µM Trolox. The extract did not show SOD mimetic activity and did not inhibit collagenase [Thring 2009].

A strong correlation ($r^2 = 0.98$) was shown between total phenolic contents of different burdock extracts (45.8% in seeds, 15.3% in leaves and 2.87% in roots) and the total antioxidant activity (0.069, 0.029 and 0.0016 mmol of Trolox/100 g dry weight) [Ferracane 2010].

The polysaccharide ALP1 isolated from the roots showed moderate ABTS radical scavenging activity, strong hydroxyl radical scavenging activity and strong ferrous ion chelating activity [Liu 2014].

Antiinflammatory effects and antiallergic properties
Diarctigenin inhibited the production of NO, prostaglandin E2, tumour necrosis factor-α, and interleukins (IL)-1β and IL-6 with IC_{50} values of 6 to 12 µM in zymosan- or lipopolysaccharide-(LPS) activated macrophages. It attenuated zymosan induced mRNA synthesis of inducible NO synthase (iNOS) and also

inhibited promotor activities of iNOS and cytokine genes in the cells. Diarctigenin inhibited the transcriptional activity and DNA binding ability of NF-κB in zymosan-activated macrophages but did not affect the degradation and phosphorylation of inhibitory κB (IκB) proteins. Moreover, it suppressed expression vector NF-κBp65-elicited NF-κB activation and also iNOS promotor activity,indicating that the compound could directly target an NF-κB activating signal cascade downstream of IκB degradation and inhibit NF-κB-regulated iNOS expression. Diarctigenin also inhibited the *in vitro* DNA binding ability of NF-κB but did not affect the nuclear import of NF-κB p65 in the cells [Kim 2008].

The butanolic fraction of an ethanolic (30%) extract significantly suppressed the dinitrophenyl-bovine serum albumin (DNP-BSA) induced β-hexominidase secretion in IgE-sensitized RBL-2H3 cells in a dose-dependent manner at 1 ($p<0.01$), 10 ($p<0.01$) and 100 μg/mL ($p< 0.05$) compared to DNP-BSA alone. In concanavalin A-treated cells, the extract significantly increased murine splenocyte proliferation at 10 and 100 μg/mL ($p<0.05$) and significantly decreased mRNA expression of IL-4 and IL-5 at 100 μg/mL and their secretion compared with concanavalin A-stimulated splenocytes ($p<0.01$). The same dose of the extract attenuated the NF-κB activation and also the phosphorylation of mitogen-activated protein kinases such as p38, c-Jun N-terminal kinase (JNK) and extracellular-signal-regulated kinases (ERK) [Sohn 2011].

Effects on glucose

Incubation of L6 myotubes with 1 μM arctigenin resulted in a 1.49-fold increase in glucose uptake, which is comparable with the effect of 100 nM insulin. Arctigenin (0.1, 0.3, 1 and 3 μM) increased basal glucose uptake in a dose- and time-dependent manner ($p<0.01$). Arctigenin (1, 3, 10 and 30 μM) dose dependently increased ($p<0.01$) AMPK and acetyl co-enzyme A synthetase (ACC) phosphorylation in L6 myotubes. Significant increases of AMPK and ACC phosphorylation were observed within 15 min after arctigenin treatment (3 μM) and were maintained for up to 120 min. Incubation of EDL or soleus muscles from C57BL/6J mice with 3 μM arctigenin resulted in an increase of glucose uptake by 31.7% ($p=0.1$) and 18% ($p<0.05$), or 42% ($p<0.05$) and 20.6% ($p<0.01$) under basal and insulin-stimulated conditions, respectively. Arctigenin (1, 3 and 10 μM) also dose-dependently increased AMPK and ACC phosphorylation in isolated EDL and soleus muscles. In primary rat hepatocytes incubation with arctigenin at 2.5, 5, 10, 20 or 40 μM for 1h increased AMPK and ACC phosphorylation in a dose-dependent manner. Glucagon induced hepatic gluconeogenesis (10 nM for 20h) was significantly suppressed by arctigenin treatment in a dose-dependent manner (10, 20 and 40 μM); arctigenin (5, 10, 20 and 40 μM) also significantly decreased the insulin stimulated synthesis (10nM) of fatty acids and sterols. The suppression of gluconeogenesis and lipid synthesis by a treatment of 20 μM arctigenin for 20 h was completely blocked by compound C pretreatment (20 μM) [Huang 2012].

At a concentration of 100 μg/mL an ethanolic extract containing approximately 15% chlorogenic acid induced a reduction in insulin release in INS-1cells in the presence of 5.6 mM of glucose ($p<0.05$) and a significant increase in glucose uptake on L6 muscular cells ($p<0.05$) in the presence of insulin (100 nM). This effect was not observed in the absence of insulin in the medium. At concentrations of 50 and 100 μg/mL, the extract showed a significant reduction in glucagon (100 nM)-induced glucose production ($p<0.01$) [Tousch 2011].

Antimutagenic / Antiproliferative effects

In *Salmonella* strain TA 98, the supernatant of a burdock root juice inhibited the mutagenicity induced by 4-nitro-1,2-diaminobenzene and 2-nitro-1,2–diaminobenzene without metabolic activation, and by ethidium bromide, 2-amino-anthracene, 3-amino-1,4-dimethyl-5H-pyrido[4,3-*b*]indole, 3-amino-1-methyl-5H-pyrido[4,3-*b*]indole with metabolic activation at 10.4 and 0.2 μg/plate, respectively. It did not inhibit mutagenicity induced by 2-(2-furyl)-3-(nitro-furyl)acrylamide (AF-2) in TA 100 strain [Morita 1984].

In human breast cancer MCF-7 cells, a metabolite of arctiin, (2*R*,3*R*)-2-(3′-hydroxybenzyl)-3-(3″,4″-dihydroxybenzyl) butyrolactone, showed significant antiproliferative activity at 10 μM ($p<0.001$) compared to control. In another experiment, this compound at 10 μM inhibited the oestradiol-mediated proliferative effect [Xie 2003].

The number of human prostate cancer PC-3 cells treated with arctiin, at doses up to 100 μM for 36, 42 and 48h in a serum-containing condition, decreased in a concentration- and time-dependent manner. According to microscopic examination, arctiin induced cell detachment from culture plates in a concentration-dependent manner. This effect was inhibited by cycloheximidine, showing that protein synthesis was required. Cells treated with 30 μM of arctiin in serum-containing medium for 24h significantly ($p<0.001$) increased MUC-1 expression (protein inhibiting cell-cell interactions) on the cell surface by up-regulating the mRNA [Huang 2004].

b-Asparagine isolated from burdock roots at a concentration of 0.4. and 4 mM induced apoptosis in Ehrlich's carcinoma tumour cells (2.5×10^5 cells/mL) by 5.4% and 87% respectively. b-Asparagine (0.075 to 75 mM) suppressed phytohaemagglutinin-induced proliferative activity of lymphocytes. Synthetic L-asparagine did not exhibit cytostatic and apoptosis-inducing activity [Boev 2005].

Arctiin inhibited the growth of human immortalized keratinocyte HaCaT cells in a dose-dependent manner. Treatment with 100 μM of arctiin for 48 h significantly ($p<0.05$) increased the percentage in the G1 phase from 38.2 to 48.8%. Arctiin had no effect or slightly affected the expression of cyclin-dependent kinase (CDK) inhibitor proteins (p21, p27, p57, p15, p18 and p19), whereas the expression of the cyclin D1 (promotor of the G1-to-S phase transition of the cell cycle) was strongly decreased in a time- and dose-dependent manner by phosphorylating the tumour-suppressor retinoblastoma protein. The down-regulation of cyclin D1 was demonstrated in human lung, colorectal, cervical, breast, melanoma, renal and prostate tumour cell lines [Matzuzaki 2008].

Two dichloromethane extracts (yield 0.12 and 0.10%) showed moderate antiproliferative activity against K562 (leukaemia) cell lines with tumour growth inhibition (TGI) of 17.06 and 3.62 μg/mL, respectively, as well as against 786-0 (renal) cell lines with TGI 155.79 and 60.32 μg/mL compared to doxorubicin as a positive control with TGI 0.03 and 0.20 μg/mL, respectively [Predes 2011].

Arctigenin extracted from seeds showed ED_{50} values of 4.5, 5.4 and 11 μg/mL for Hep G2 (human liver carcinoma), A459 (lung cancer) and Kato III cells (stomach cancer) respectively, whereas ED_{50} values for normal cells were more than 100μg/mL. Incubated with arctigenin (50 μg/mL) for 4, 8, 24 and 48 h, A459 cell numbers slightly decreased ($p<0.01$) with the treatment time compared to control (PBS) whereas the number of lung normal diploid fibroblast (WI-38) cells did not change with or without treatment with arctigenin. After incubation with 50 μg/mL of arctigenin for 4h, caspase-3 activity is significantly increased in A459 cells ($p<0.01$) in a time-dependent manner and slightly increased in normal WI-38cells. It was shown that activation of caspase-3 activity by arctigenin was correlated

with the decrease in the viability of both cancer and normal cells ($p<0.01$) [Suzanti 2012].

An ethanolic extract containing 23.5 ± 1.8 mg/g total polyphenols expressed as gallic acid showed antileukaemic properties against J-45.01 human T cell leukaemia cell line with an IC_{50} of 0.35 ± 0.03 mg/mL [Wegiera 2012].

Other effects
Arctigenin (isolated from a CH_2Cl_2 fraction of a methanolic extract of *T. nucifera*) at 0.1-1 µM inhibited LPS-inducible phosphorylation of MAP kinases ERK1/2, p38 kinase and JNK1/2 in Raw 264.7 cells after 1 h of contact. Arctigenin inhibited the activity of MKK1 with an IC_{50} of 1 nM. Arctigenin (0.01-1µM) inhibited LPS-inducible Activator Protein-1 (AP1) DNA binding and it was shown that arctigenin significantly inhibited AP-1-mediated reporter gene expression at 0.01 µM and 0.1 µM ($p<0.05$) and 1 µM ($p<0.01$) compared to LPS alone. After 24h of incubation, arctigenin at 1µM significantly ($p<0.01$) inhibited by 30% the production of TNF alpha in LPS-treated macrophages compared to LPS alone [Cho 2004].

In myoblasts isolated from 1 to 3-day-old newborn ICR mice limbs, arctiin at 2.5 µg/mL significantly ($p<0.01$) inhibited intracellular cAMP phosphodiesterase and significantly ($p<0.05$) increased intracellular cAMP and the amount of cell total protein [Gu 2008].

Burdock inulin (1% w/V) significantly stimulated the anaerobic growth of *Bifidobacterium adolescentis* as compared to control ($p<0.05$) [Li 2008].

After incubation for 2h with 125 to 1000 ppm of an aqueous extract (12.8 mg/g of polyphenols expressed as gallic acid), the viability of RGM1 cells treated with 250 ppm indomethacin increased significantly ($p<0.05$) in a dose-dependent manner similar to sucralfate [Chen 2009].

Arctigenin, isolated from roots at 6.25, 12.5 and 25 µM, inhibited T lymphocytes activated by anti-CD3/CD28 Ab ($p=0.0374$) and suppressed IL-2 ($p=0.0278$) and IFN-gamma ($p=0.0642$) production in a concentration-dependent manner. After 3 days of incubation with arctigenin, the ratio of IL-2 to GAPDH mRNAs in the activated T lymphocytes were significantly decreased by the three concentrations ($p=0.01$) and the ratio of IFN-gamma to GAPDH mRNAs was significantly decreased by 25 µM arctigenin ($p<0.01$) compared to cells treated with DMSO and anti-CD3/CD28. In Jurkat cells, arctigenin significantly decreased NF-AT-mediated reporter gene expression in a dose-dependent manner ($p=0.0418$) [Tsai 2011].

In the MTT assay, arctiin significantly increased viability of retinal microvascular endothelial cells in a dose-dependent manner when compared to control ($p<0.01$) [Lu 2012].

The *n*-hexane fraction of an ethanolic extract (containing *a*-linoleic acid, methyl *a*-linolenate and methyl oleate) reduced HepG2 cellular lipid synthesis and increased phosphorylation of acetyl-coenzyme A carboxylases on serine 79. It decreased fatty acid synthase protein level in a time and dose-dependent manner in HepG2 cells and stimulated AMPK phosphorylation in a time- and dose-dependent manner through the LKB1 pathway [Kuo 2012].

Arctigenin depolarized mitochondrial membrane potential in a dose-dependent manner but with a mild effect (max effect lower than 30%) and dose-dependently increased the AMP/ATP ratio in L6 myotubes. Arctigenin produced a dose dependent inhibition of oxygen consumption with complex I-linked substrate ($p<0.01$), but not with complex II-linked respiration. Arctigenin (3 µM) significantly increased lactate production in L6 myotubes after 1 and 4h ($p<0.01$) [Huang 2012].

Ex vivo experiment
Goto-Kakizaki rats (a diabetic animal model) in non-fasting conditions were given a decoction *ad libitum* (125 g/L; mean consumption 42.3 mL/day) for 4 weeks. At 4 weeks, rat liver mitochondria were isolated and respiratory parameters evaluated. Compared to control, decreases in state 3 (50% inhibition; $p<0.001$) and carbonyl cyanide p-trifluoro-methoxy-phenylhydrazone (about 30% inhibition; $p<0.01$) respirations were observed. The respiratory control ratio was reduced by approximately 40% ($p<0.05$) [Ferreira 2010].

In vivo experiments

Antioxidant activity
Doses of 100 to 400 mg/kg b.w. of the polysaccharide ALP1 isolated from the roots significantly ($p<0.01$) enhanced anti-oxidant enzyme activities and total antioxidant capacity and decreased the levels of malondialdehyde (MDA) in both the serum and liver of aging mice [Liu 2014].

Antiviral properties
Ten BALB/C mice, intranasally infected with influenza A virus (H1N1), received arctiin (5 mg/day) or oseltamivir (0.2 mg/day) orally, twice a day, for 7 days. Half of the mice were also injected s.c. with 0.5 mg of 5-fluorouracil (5-FU), every other day from 7 days before virus inoculation to 13 days afterwards. At day 3, arctiin alone significantly ($p<0.01$) reduced the virus titre in the lungs and in bronchoalveolar lavage fluids compared to control, whereas no reduction was observed in mice treated with arctiin and 5-FU. By day 7, arctiin had reduced the virus production in the 5-FU group, but to a lower extent than oseltamivir. There was no significant difference in antibody response to influenza A virus in any of the groups at day 3, but a marked increase of sera antibody titre in mice which did not receive 5-FU was observed at day 7. Arctiin produced a higher antibody titre than oseltamivir or control in 5-FU mice at day 7. In another experiment, 18 mice infected with influenza A virus received orally arctiin (1 mg/day) or oseltamivir (0.02, 0.05 or 0.2 mg/day) alone or in combination, twice a day for 3 days after virus inoculation. In the bronchoalveolar lavage fluids, the combination of arctiin and oseltamivir significantly reduced the virus titres to 21% ($p<0.001$), 29% ($p<0.01$) and 60% ($p<0.01$) compared to oseltamivir alone. In the lungs, the combination with the lower doses of oseltamivir decreased the virus titres to 61% ($p<0.001$) and 64% ($p<0.01$), compared to oseltamivir alone [Hayashi 2010].

Antimutagenic / Antitumour effects
In mice, s.c. administration of a fresh burdock root methanolic extract inhibited the growth of Ehrlich ascites carcinoma with a test to control ratio of 0.6 and 0.8 at dose levels of 340 and 160 mg/kg b.w. respectively, 24 h after transplantation. An aqueous fraction of an ethanolic extract (310 mg/kg b.w.) and a dichloromethane extract (310 mg/kg b.w.) gave a test to control ratio of 0.5 and 0.57 respectively, 48h after transplantation. The methanolic extract caused haemorrhagic necrosis and liquefaction of the established solid Yoshima sarcoma at 400 mg/kg b.w. [Dombradi 1966].

Female Sprague-Dawley rats were administered intragastric doses of 2-amino-1-methyl-6-phenylimidazol[4,5-*b*]pyridine (PhIP) at 100 mg/kg b.w. once a week for 8 weeks in order to induce breast cancer. Three days later the rats were divided into three groups, receiving either a basal diet or a diet containing 0.2 or 0.02% arctiin for 40 weeks. A further three

groups without PhIP initiation were given the same test diets. Carcinoma multiplicity was significantly ($p<0.05$) decreased in arctiin treated rats compared to the PhIP/basal diet control. The number of colon aberrant crypt foci also significantly ($p<0.05$) decreased in both arctiin groups while the incidence and multiplicity of pancreatic lesions was not significantly different from the PhIP/basal diet group. Two weeks after a single injection of diethylnitrosamine (DEN) at 200 mg/kg b.w., male F344 rats received a diet containing either 0.03% 2-amino-3,8-dimethylimidazo[4,5-*f*]quinoxaline (MeIQx) alone, MeIQx with 5% arctiin, 0.1% arctiin or basal diet for 6 weeks. The average number and area of preneoplastic glutathione S-transferase placental positive foci significantly increased in the hepatocarcinogen MeIQx alone group (21.1 ± 9.6 and 1.7 ± 1.0 respectively) and MeIQx associated with 0.5% arctiin (28.0 ± 5.6 and 2.6 ± 0.6 respectively) compared to basal diet control values (6.3 ± 1.4 and 0.5 ± 0.2 respectively). In contrast, treatment with 0.1% arctiin alone after DEN administration did not affect foci development [Hirose 2000].

Gastrointestinal effects
In female Wistar rats, oral doses of 10, 30 and 100 mg/kg b.w. of a chloroform extract (DER = 104:1) significantly ($p<0.05$) reduced the acute gastric lesions induced by an oral dose of 80% ethanol by 61%, 70% and 76% respectively, compared to 75% by omeprazole (40 mg/kg b.w.). The same extract administered orally at 100 mg/kg b.w. daily for 7 days reduced the chronic gastric ulcerations induced by acetic acid by 52% while omeprazole (20 mg/kg b.w.) reduced them by 71% ($p<0.05$). After pylorus ligatures, intraduodenal administration of 100, 300 and 600 mg/kg b.w. of the extract reduced the total acidity of gastric secretion by 22, 22 and 33% respectively, whereas i.p. administration inhibited total acidity by 50, 60 and 67% respectively. *In vitro*, the extract inhibited H^+, K^+-ATPase activity with an IC_{50} of 53 µg/mL and a fraction (*n*-hexane/ethyl acetate 3:1 *v/v*) of this extract containing unsaturated fatty acids and esters (30 and 100 µg/mL) by 48% and 89% respectively. In female Swiss mice treated orally with 30, 100 and 300 mg/kg b.w., the gastric emptying and the intestinal transit were not altered [Dos Santos 2008].

In Swiss mice, an aqueous dry extract (1:10 m/V) orally administered at 500 mg/kg for 24 days had no effect on abdominal lesions caused by the parasite *Angiostrongylus costaricensis* [Fante 2008].

In female Kunming mice receiving a diet containing 5% of burdock inulin for 14 days, the proliferation of caecal Bifidobacteria and Lactobacilli was significantly improved compared to control group ($p<0.05$). Enterobacteria and Enterococci counts were not significantly affected [Li 2008].

Male Wistar rats were orally treated with 260, 1300 and 2600 mg/kg b.w. of an aqueous extract (12.8 mg/g of polyphenols expressed as gallic acid) before administration of a dose of 10 mL/kg b.w. of 70% ethanol. In the verum groups the gastric mucosal lesions were 16.67, 57.22 and 48.72 mm^2 respectively, whereas without burdock treatment, the lesion area was 132.95 mm^2 ($p<0.05$) [Chen 2009].

In female Wistar rats, oral administration of an ethanolic extract (1, 3, 10 and 30 mg/kg b.w., twice daily for 7 days) significantly ($p<0.001$) reduced acetic acid-induced gastric ulceration by 29.2%, 41.4%, 59.3% and 38.5% respectively, when compared to control; whereas a dose of 100 mg/kg b.w. did not reduce gastric lesions. At 10 mg/kg, the extract did not increase the gastric mucus content but did induce cell proliferation in the stomach according to proliferating cell nuclear antigen expression. Compared to control, the 10 mg/kg extract also significantly ameliorated acetic acid-induced ulcer-associated increases in SOD activity ($p<0.01$), lipid hydro-peroxide levels ($p<0.05$), myeloperoxidase activity ($p<0.01$) and microvascular permeability ($p<0.01$), and the reduction in glutathione ($p<0.001$). Intraduodenal administration of doses of 10 and 30 mg/kg b.w., immediately after pyloric ligation, reduced the gastric volume from 6.0 ± 0.5 mL (control group) to 3.0 ± 0.1 mL and 3.4 ± 0.5 mL respectively, and acidity of gastric secretion by 80% and 72% respectively when compared to control ($p<0.001$). At 100 mg/kg, the extract did not affect gastric acid secretion [da Silva 2013].

Diuretic activity
In male albino rats, an oral dose of 175 mg/kg b.w. of a 50% ethanolic extract induced diuretic activity after 5h compared to urea (75 mg/100 g) [Sharma 1978].

An infusion (3 g/L) ingested *ad libitum* by 12 female Wistar rats for 12 days showed beneficial effects on urolithiasis by increasing urinary pH [Grases 1994].

Hepatoprotective effects
After i.p. injection of carbon tetrachloride in rats, an aqueous extract (DER 4:1) dose-dependently decreased serum GOT and GPT levels when administered i.p. at 100 ($p<0.05$), 300 ($p<0.01$) and 1000 mg/kg b.w. ($p<0.01$), compared to control. Doses of 300 and 1000 mg/kg showed greater activity than silymarin at 25 mg/kg. The liver of animals treated with the extract exhibited a marked reduction in necrosis [Lin 1996].

In male ICR mice an aqueous dry extract, orally administered at a dose of 300 mg/kg b.w., significantly suppressed the SGOT and SGPT elevation induced by 32 µL/kg of carbon tetrachloride, i.p. ($p<0.001$) or 600 mg/kg of paracetamol, i.p. ($p<0.05$). The extract significantly reversed the decrease of glutathione concentration ($p<0.05$) and of cytochrome P450 activity ($p<0.001$) in both groups whereas it decreased significantly the liver malondialdehyde content ($p<0.01$ and $p<0.001$ respectively). After treatment with the extract, lesions induced by carbon tetrachloride and paracetamol were reduced and hepatocytes were regenerated [Lin 2000].

Groups of 10 Wistar rats were treated as follows: one group was fed a liquid ethanolic diet (4 g absolute ethanol / 80 mL liquid ethanol) for 28 days and another received the same treatment and an i.p. injection of carbon tetrachloride (0.5 mL/kg b.w.) on the 21st day. Both groups received orally 300 mg/kg of an aqueous extract of burdock root, 3 times per day at day 22. In a second experiment, the pre-treatments with ethanol and ethanol / carbon tetrachloride were the same but the extract was administered 3 times daily from day 22 to day 28. No significant differences were observed between liver weights for all groups. The extract significantly improved serum levels of transaminases (SGOT and SGPT), triglycerides hepatic glutathione, cytochrome P450, cytochrome b5, NAPH cytochrome c reductase and MDA levels which were increased by ethanol and ethanol plus carbon tetrachloride pre-treatments. The extract restored the histopathological lesions induced by these substances [Lin 2002].

An extract (1:5; ethanol 70 %) was tested for liver protective effects against experimentally-induced cadmium toxicity in male Wistar rats. The extract was administered by gavage at a daily dose of 300 mg/kg b.w. for 7 or 56 days, either alone or after a single i.p. injection of cadmium chloride, saline solution was used as a control. At days 7 and 56, compared to control, plasma GOT was significantly higher in rats administered cadmium, but not in those co-administered the extract. Plasma GPT was significantly lower than control in rats given the extract, with

or without cadmium, at day 7 but not day 56. Liver GOT was significantly higher in rats given cadmium, with or without the extract, at day 7, but only in the group given both at day 56. No alterations in plasma levels of creatinine, total bilirubin and total protein were observed at days 7 or 56 [De Souza Predes 2014].

Effects on glucose
In non-fasting conditions, a decoction given *ad libitum* (125 g/L; mean consumption of 42.3 mL/day) for 4 weeks induced a significant ($p<0.05$) decrease in glucose levels in Goto-Kakizaki rats. No difference in glucose levels was observed under fasting conditions (16-18 h) and 2 h after i.p. glucose loading (1.8 g/kg b.w.) as compared to control [Ferreira 2010].

Wistar rats received 15 mg of an ethanolic extract by gavage or i.p. daily for 4 days. On the fourth day a glucose tolerance test was performed by oral (OGTT, 3 g/kg) or i.p. (IPGTT, 1 g/kg) glucose administration. After oral administration of the extract a rapid reduction in hyperglycaemia associated with a significant transient increase in plasma insulin was observed ($p<0.05$), whereas after i.p administration the extract did not modify glucose tolerance [Tousch 2011].

In C57BL/J6 mice, pre-treatment with 300 mg/kg b.w. arctigenin by gavage decreased blood glucose levels. The phosphorylation of AMPK and ACC liver isolated from arctigenin–treated mice was significantly increased by 36% and by 74% ($p<0.01$) respectively [Huang 2012].

Oral administration of an ethanolic extract (400 mg/kg) daily for 14 days to streptozotocin-induced diabetic rats significantly ($p<0.01$) decreased blood glucose (31.5%), body weight, serum triglycerides, total cholesterol, LDL levels, serum urea, creatinine and MDA levels in liver and kidney tissues at the end of the experiment compared to diabetic control. Serum insulin, muscle glycogen content and HDL level were significantly increased ($p<0.01$) as was liver glycogen content ($p<0.05$) [Cao 2012].

Streptozotocin-induced diabetic rats received arctiin at 40 or 60 mg/kg b.w. i.p.daily for 8 weeks. These treatments significantly decreased the levels of 24h-urinary albumin ($p<0.01$), prevented glomerulosclerosis and effectively restored glomerular filtration barrier damage ($p<0.01$) compared to non-treated diabetic rats; up-regulating the expression of nephrine and podocine and down-regulating heparanase [Ma 2012].

Three groups (n = 20) of male Sprague-Dawley rats with streptozotocin-induced diabetic retinopathy received daily oral doses of arctiin of 30, 90 and 270 mg/kg b.w. for 16 weeks. The serum glucose level was significantly decreased by the highest dose of arctiin from weeks 8 to 16 when compared to week 0 ($p<0.05$) whereas the lower doses demonstrated no effect at the end of the experiment. The glycated haemoglobin (HBA1c) level was significantly decreased at week 8 with the dose of 270 mg/kg of arctiin and at week 16 with the two other doses ($p<0.05$). In retinal tissue, the inner plexiform layer or the rod layer were restored, and angiogenesis was decreased in a dose-dependent manner [Lu 2012].

Three groups (n=10) of male Sprague-Dawley rats with cationic bovine serum albumin (cBSA)-induced glomerulonephritis received oral doses of arctiin at 30, 60 and 120 mg/kg b.w. per day for three weeks (starting one week after initial cBSA injection). Levels of urinary protein had decreased at weeks 2, 3 and 4 at the doses of 60 and 120 mg/kg ($p<0.05$ or $p<0.01$) but only at week 4 at 30 mg/kg, compared to control. When compared to control, all three arctiin dosages at week four demonstrated a dose-dependent signfificant ($p<0.05$ or $p<0.01$) decrease in serum blood urea nitrogen, creatinine, IL-6 and TNF-α levels, as well as significantly ($p<0.01$) decreasing the level of malondialdehyde and NF-κB DNA binding activity, and increasing super oxide dismutase activity. The parameters of renal lesion such as hypercellularity, infiltration of polymorphonuclear leukocyte, fibrinoid necrosis, focal and segmental proliferation and interstitial infiltration were ameliorated in arctiin-treated animals compared to control group [Wu 2009].

A single oral administration of arctigenin (200 mg/kg b.w.) to ob/ob mice significantly decreased blood glucose levels ($p<0.01$) by 34.2% after 2h compared to vehicle only control. Chronic oral administration of the same dose for 23 days significantly decreased random and fasting blood glucose levels with an average reduction rate over that period of 32.2% ($p<0.05$) and 35.2% ($p<0.05$ and $p<0.01$) compared to control. Chronic i.p. administration of arctigenin (25 mg/kg, twice daily) to ob/ob mice for 22 days significantly increased ($p<0.05$) insulin-stimulated AKT phosphorylation in gastrocnemius muscle and liver, but not in perirenal fat. The treatment had no effect on GLUT4 levels in gastrocnemius muscle and had no significant effect on hepatic Pepck expression, but did significantly decrease G6pase mRNA expression ($p<0.05$) [Huang 2012].

Clinical Studies
No published clinical data currently available.

Pharmacokinetic properties

Pharmacokinetics in vitro
Arctiin was stable after incubation for up to 24h with gastric juice (pH 1.2-1.5) of male Wistar rats at 37°C. After incubation for 24h with 5 mL of the suspension of intestinal flora obtained from gut, at 37°C, arctiin (500 µg) was transformed into arctigenin (55.4% of arctiin) after 1h and further metabolised into 2-(3'',4''-dihydroxybenzyl)-3-(3',4'-dimethoxybenzyl)-butyrolactone after 3h (90.9%) [Nose 1992].

A weak inhibition of cytochrome CYP3A4 (<13.5%), CYP19 (<28.5%) and CYP2C19 (<25%) was observed with a 55% ethanolic extract of burdock root (DER 2.6-4.6:1) [Scott 2006].

Metabolism
After incubation with human faecal inoculum, arctigenin was metabolized to enterolactone, 3'-demethyl-4'-dehydroxy-arctigenin and 3'demethylarctigenin, an isomer of matairesinol [Heinonen 2001].

Six metabolites were identified after anaerobic incubation of arctiin with a mixture of human faecal bacteria: (-)-arctigenin, (2*R*,3*R*)-2-(3',4'-dihydroxy-benzyl)-3-(3'',4''-dimethoxybenzyl) butyrolactone, (2*R*,3*R*)-2-(3'-hydroxybenzyl)-3-(3'',4''-dimethoxybenzyl)-butyrolactone, (2*R*,3*R*)-2-(3'-hydroxybenzyl)-3-(3''-hydroxy-4''-methoxybenzyl)butyrolactone, (2*R*,3*R*)-2-(3'-hydroxybenzyl)-3-(3'',4''-dihydroxybenzyl)butyrolactone and (-)-enterolactone [Xie 2003].

Pharmacokinetics in vivo
After i.v. injection of 0.3 mg/kg b.w of arctigenin to Wistar rats, the C_{max}, half life and AUC were 323 ± 65.2 ng/mL, 0.830 ± 0.166 and 81.0 ± 22.1 hng/mL, respectively [Zou 2013].

After oral administration of 30, 50 and 70 mg/kg b.w of arctigenin to Sprague-Dawley rats, the AUC values in plasma were 86.4 ± 11.4, 206.2 ± 57.3, and 261.7 ± 61.4 mg/mL, respectively; arctigenin was undetected after 4h. T_{max} was 90 min for the 3 doses [He 2013].

Metabolism
In BALB/c mice, arctiin was immediately hydrolysed to arcti-

genin after oral administration (5.0 mg/mL in 1% ethanol). The metabolite was present in the blood for over 12 h [Hayashi 2010].

After oral administration of arctigenin to Sprague Dawley rats, three metabolites were identified in plasma: arctigenic acid, 4-*O*-demethyl-arctigenin and arctigenin-4-*O*′-glucuronide [Gao 2013].

Distribution
In adult Sprague Dawley rats, the AUC of arctiin was not proportional to the orally administered dosage (30 to 70 mg/kg b.w.). Half-life, elimination rate constant, absorption rate constant, peak concentration, apparent volume, total body clearance and area under curve values of arctiin were significantly different in female compared to male rats ($p<0.05$) [Fan 2011].

The terminal half-life of arctiin and arctigenin was not found to be dose proportional in adult Sprague Dawley rats orally adminstered 25, 50 and 100 mg/kg of arctiin. Thirty minutes after administration the highest arctiin concentration was found in the spleen, followed by the liver, heart, small intestine, stomach, lungs and kidneys. The highest arctigenin concentration was found in the stomach and the small intestine, the lowest in the liver. Three hours after administration the tissue concentrations of the two compounds decreased markedly in all tissues, but especially in the spleen [He 2012].

After oral administration to Sprague Dawley rats, the highest content of arctigenin was found in the spleen: two times greater than in liver and several times more than other organs [He 2013].

Excretion
Following an oral daily dose of 120 mg/kg b.w. of arctiin for 20 days, three metabolites were identified in the faeces of Sprague Dawley rats: (-)-enterolactone (M1), (-)-arctigenin (M2) and [(2*R*,3*R*)-2-(3′-hydroxybenzyl)-3-(3′′,4′′-dimethoxybenzyl)-butyrolactone] (M3). After a dose of 30 mg/kg b.w. of arctiin by oral gavage, the total cumulative excretion rates of arctiin, M1, M2 and M3 were 19.84%, 0.35%, 0.28% and 0.02% in urine and 1.80%, 35.80%, 0.30% and 0.48% of intragastric dose in faeces, respectively. Excretion rate of M1 reached 35.80% in faeces, whereas the excretion rates of the two other metabolites were lower in urine and faeces. The cumulative excretion rate of arctiin and its metabolites reached a steady state from 76 to 96 h [Wang 2013].

Preclinical safety data

Acute toxicity
The i.p. LD_{50} of a 50% ethanolic extract was 700 mg/kg b.w. in albino rats [Sharma 1978].

In male Wistar rats, the oral LD_{50} of an aqueous extract (100 g, DER = 4:1) was higher than 2 g/kg b.w. [Lin 2002].

After 72h, mortality and toxic reactions were not observed in Sprague Dawley rats after oral administration of dosages up to 3 g/kg b.w. of an ethanolic dry extract 70% V/V (1:10 w/v) [Cao 2012].

Neither mortality, significant difference in body weight development nor signs of toxicity were observed in female Wistar rats after oral administration of up to 100 mg/kg b.w. of an ethanolic extract, twice daily for 7 days [da Silva 2013].

Repeated dose and chronic toxicity studies
Inbred strain ACI rats were fed with a basal diet mixed with 33% dried and powdered burdock root for 120 days and then returned to the basal diet for 120 days. At the end of the experiment, no tumours were detected [Hirono 1977].

In female Sprague Dawley rats receiving either 0.2% or 0.02% arctiin included in their diet for 48 weeks, no mammary tumours or pancreatic lesions were found, but a significant decrease in body weight gain was observed (448 ± 88 g, $p<0.05$ and 416 ± 26 g, $p<0.01$, respectively) [Hirose 2000].

No intestinal discomfort such as eructation or bloating was observed in female Kunming mice receiving a diet containing 5% of burdock inulin for 14 days [Li 2008].

Body weights of male Sprague Dawley rats fed with 500 and 1000 mg/kg b.w. of burdock root for 4 weeks significantly ($p<0.05$) decreased as compared to control, whereas 100 mg/kg of burdock root had no effect [Kuo 2012].

Chronic oral administration of arctigenin (200 mg/kg b.w.) for 23 days did not induce changes in body weight, but did cause a significant reduction of subcutaneous ($p<0.05$; 21)) but not perirenal or mesenteric fat weight, and significantly decreased cholesterol levels ($p<0.05$) [Huang 2012].

Lappaol F administered at 5 or 10 mg/kg b.w. for 15 days was well tolerated in mice, without significant toxicity [Sun 2013].

Reproductive toxicity
An aqueous extract did not affect fertility of female mice after s.c. administration twice a day for five days [Matsui 1967].

Clinical safety data

A 20% aqueous solution of a propylene glycol extract of burdock root (no further details), applied to the skin of volunteers according to the Jadssohn block test, did not induce skin sensitisation or skin and eye irritation [Yotchokova 1990].

Three cases of contact dermatitis caused by burdock root plasters applied for anti-inflammatory purposes have been reported [Rodriguez 1995].

In a 53-year-old Japanese man with multiple prior episodes of urticaria following ingestion of boiled burdock, an anaphylactic reaction was observed after further ingestion of boiled burdock in a meal. Immediate type allergic reaction to boiled and raw burdock was confirmed after medical tests [Sasaki 2003].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ARNICAE FLOS

2019

Arnica flower

DEFINITION

Arnica flower consists of the whole or partially broken, dried flower-heads of *Arnica montana* L. It contains not less than 0.4 per cent m/m of total sesquiterpene lactones expressed as dihydrohelenalin tiglate, calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Arnica flower].

Fresh material may also be used, provided that when dried it complies with the monograph of the European Pharmacopoeia.

CONSTITUENTS

Sesquiterpene lactones of the pseudoguaianolide type, 0.2-0.8%; principally helenalin and 11α,13-dihydrohelenalin and their esters with acetic, isobutyric, methacrylic, tiglic and other carboxylic acids. Other constituents include diterpenes, arnidiol (a triterpene), flavonols, flavonol glycosides and -glucuronides, pyrrolizidine alkaloids (tussilagine and isotussilagine), polyacetylenes, caffeic acid and derivatives, coumarins, fatty acids and carotenoids [Santer 1962; Güntzel 1967; Schulte 1969; Kating 1970; Vanhaelen 1973; List 1974; Willuhn 1983, 1994; Merfort 1984, 1985, 1986, 1987, 1988a,b, 1992a,b,c; Schmidt 1992; Paßreiter 1992a, b; Kolodziej 1993, Pietta 1994; Kos 2005; Teuscher 2016].

CLINICAL PARTICULARS

Therapeutic indications

External use
Treatment of bruises, sprains and inflammation caused by insect bites; gingivitis and aphthous ulcers; symptomatic treatment of rheumatic complaints and muscular pain [Hänsel 1991; Van Hellemont 1988; Hänsel 1991; Merfort 1992b; British Pharmacopoeia 1996; Knuesel 2002; Alonso 2002; Widrig 2007; Mendes 2008; Ross 2008; Pumpa 2014; Teuscher 2016; Simsek 2016; van Exsel 2016].

Posology and method of administration

Dosage

External use
Ointments, creams, gels or compresses made with 5-50% V/V tinctures or 5-25% V/V fluid extracts; diluted tincture (1:3 to 1:10), diluted fluid extracts or a decoction of 2.0 g of dried arnica flower in 100 ml of water [Merfort 1992b; Knuesel 2002; Widrig 2007; Mendes 2008].

Method of administration
Topically as diluted tincture, ointment, cream, gel or compress [Merfort 1992a,b; Knuesel 2002; Widrig 2007; Mendes 2008].

Duration of use
If symptoms persist or worsen, medical advice should be sought.

Contraindications
Allergy to Arnica or other members of the Compositae [Eberhartinger 1984; Hausen 1985; Machet 1993; Hörmann 1995].

Special warnings and precautions for use
For external use only.

Interaction with other medicaments and other forms of interaction
None reported.

E/S/C/O/P MONOGRAPHS

Pregnancy and lactation
No restriction for external use; no harmful effects have been reported.

Effects on ability to drive and use machines
None known.

Undesirable effects
Skin irritation has been reported. Contact dermatitis from arnica may occur in susceptible individuals [Herrmann 1978; Hausen 1978, 1979, 1980, 1985, 1997; Eberhartinger 1984; Machet 1993; Hörmann 1995; Reynolds 1996; Spettoli 1998; Widrig 2007; Jocher 2009; Roth 2012].

Overdose
Not applicable to external use.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Anti-inflammatory activity
The effect of three tinctures (fresh flowerheads of Central European chemotype, 1:20, 70%v/v; dried flowerheads of Central European chemotype, not further specified; dried flowerheads of Spanish chemotype, not further specified) and a gel (50 g tincture of fresh flowerheads of Central European chemotype, 1:20, 70% v/v in 100 g gel) on IL-1β-induced MMP1 and MMP13 gene expression in primary bovine and human articular chondrocytes was investigated. The ability to inhibit DNA binding of the transcription factors AP-1 and NF-κB was also studied. The increased expression levels of MMP1 and MMP13 in IL-1β stimulated chondrocytes were concentration-dependently reduced following pre-treatment with arnica. All preparations inhibited AP-1 and NF-κB DNA binding in both cell lines in a concentration-dependent manner [Jäger 2009].

The production of cytokines was measured in H_2O_2-inflamed mouse fibroblast cells (NCTC clone L929), with and without pre-treatment with extracts enriched in polysaccharides (0.36% m/m) or polyphenols (18.44% m/m). The secretion of IL-8 and TNF-α was significantly ($p<0.05$) lower in cells pre-treated with the extracts [Gaspar 2014].

An extract (not further specified, yield 3.8%) showed inhibition of 5-LOX (IC_{50}=9 ng/mL) and COX-1 (IC_{50}= >50µg/mL) [Chagas-Paula 2015].

In mouse and rat liver homogenates and human polymorphonuclear neutrophils, helenalin and 2,3-dihydrohelenalin significantly suppressed various parameters of inflammation; at 5×10^{-5} M they inhibited the chemotactic migration of human polymorphonuclear neutrophils by 100% and 20% respectively [Hall 1980]. Unsaturated structures such as α-methylene-γ-lactone and/or α,β-unsubstituted cyclopentenone moieties (helenalin has both) seem to play a role in the anti-inflammatory activity. The compounds exerted their activities at multiple receptor sites, e.g. by suppression of the synthesis of prostaglandins at 10^{-3} M in a prostaglandin synthetase assay and uncoupling of oxidative phosphorylation of human polymorphonuclear neutrophils at 5×10^{-4} M [Hall 1979, 1980].

Helenalin and (to a much lesser degree) 11α,13-dihydrohelenalin inhibited NF-κB activation in response to four different stimuli in T-cells, B-cells and epithelial cells. Inhibition was seen at the µM level and was selective. The activities of transcription factors Oct-1, TBP, Sp1 and STAT5 were not affected [Lyss 1997]. Inhibition of the activation of transcription factor NF-AT has also been demonstrated [Klaas 2002].

The electrophoretic mobility shift assay was performed with isolated sesquiterpene lactones (helenalinisobutyrate 39.89 mg/100 ml; 11α,l3-dihydrohelenalinmethacrylate 69.93 mg/100 ml; 11α,13 dihydrohelenalinisobutyrate 69.93 mg/100 ml) at doses of 20µL and 50µL. An activation of NF-κB DNA binding in dendritic cells was observed at low concentrations and an inhibition at high concentrations [Lass 2008].

Activated Jurkat CD4+ T cells were exposed for 24h to various concentrations of helenalin (0.5 µM, 0.75 µM, 1 µM and 2 µM). Helenalin significantly ($p<0.05$) reduced proliferation in a dose-dependent manner by triggering the mitochondrial pathway of apoptosis. Activated CD4+ T cells which survived exposure to helenalin exhibited a cell cycle arrest in the G2/M phase [Berges 2009].

The interactions of helenalin with the NF-κB protein p65 (RelA), with recombinant IκB kinases (IKKs) α and β, and with glutathione, were characterized with a surface plasmon resonance-based method. Helenalin interacted with the NF-κB protein RelA, but not with IKKα or IKKβ or with glutathione. The influence of the binding between helenalin and RelA on the binding of RelA to double-stranded DNA carrying NF-κB binding sequences was analysed. At physiological pH 7.4, helenalin inhibited the binding of RelA to the DNA NF-κB binding sites with an IC_{50} of 5.0 ± 2.8 µM, while at pH 8.0 the IC_{50} value was approximately 3-fold higher [Büchele 2010].

Antimicrobial activity
Using isolated constituents such as helenalin and 11,13-dihydrohelenalin acetate, antimicrobial activity against the Gram-positive bacteria *Arthrobacter citreus*, *Bacillus brevis*, *Bacillus subtilis*, *Corynebacterium insidiosum*, *Micrococcus roseus*, *Mycobacterium phlei*, *Sarcina lutea* and *Staphylococcus aureus* and Gram-negative *Proteus vulgaris*, was demonstrated [Lee 1977; Willuhn 1982; Merfort 1992a]. Antifungal activity of helenalin and derivatives against *Botrytis cinerea* has also been demonstrated [Willuhn 1982].

Some sesquiterpene lactones including helenalin showed activity against *Trypanosoma brucei rhodesiense* and *T. cruzi* in rat skeletal myoblasts (L-6 cells) infected with trypomastigotes. Helenalin was most effective against *T. brucei* (IC_{50}=0.051µM) and *T. cruzi* (IC_{50}=0.695 µM) and showed less cytotoxicity against L-6 cells (LC_{50}=0.992µM) [Schmidt 2002].

Mammary epithelial T-cells were incubated with 10 µM helenalin, then stimulated with TNF-α and finally infected with *Staphylococcus aureus*. A significant ($p<0.05$) reduction of the multiplication of *S. aureus* in comparison with the control group was shown after 6 and 9 hours. The same effect was observed under non-inflammatory conditions [Boulanger 2007].

Antioxidant effects
An extract (not further specified, yield 10.9%) was tested for its ability to inhibit the lipid peroxidation induced by the Fe^{3+}/ascorbate system in a young rat brain cytosolic fraction and on DPPH, H_2O_2, superoxide and NO radicals. The radical-scavenging activity of the extract was dose-dependent and significant ($p<0.05$) [Sharma 2016].

The effect of concurrent treatment (10-100 mg/L) and pre-treatment (24h, 10-100 mg/L) with an extract (not further specified) on H_2O_2-induced (50µM) oxidative stress in NCTC cells was studied. Co-treatment did not increase cell viability

or decrease LDH secretion as compared to controls. In contrast, pre-treatment showed a significant ($p<0.01$) increase in cell viability and a decrease in LDH secretion. In the co treated cells a significant ($p<0.01$) difference in cell cycle distribution was observed as compared to the untreated controls, pre-treatment showed no significant difference [Craciunescu 2012].

Immunotoxic effects
Treatment of THP-1 cells positive for intracellular ROS with helenalin resulted in a significant ($p<0.01$) increase of positive cells from 6.6% to 26.5% (IC_{10}=0.52µM) and 55.7% (IC_{50}=1.16µM) respectively. In Jurkat cells, a significant increase of intracellular ROS was not observed. The treatment of THP-1 cells with subtoxic concentrations of helenalin (IC_{10} =0.52µM) lead to a significant ($p<0.05$) influence on protein folding, the intrinsic apoptosis pathway, and carbohydrate metabolism shifting the cells to anaerobic glycolysis. Human peripheral blood mononuclear cells showed a decreased secretion of various cytokines after helenalin (IC_{10} =0.52µM) treatment [Zwicker 2017].

Cytotoxic effects
Cell viability of NCTC mouse fibroblasts was significantly ($p<0.01$) decreased by an ethanolic extract (70% v/v; yield 18.4%) at concentrations above 100 mg/L (300 to 1000 mg/L) in comparison to control. Whereas at concentrations of 10 mg/L and 100 mg/L, cell viability was more than 80% compared to control [Craciunescu 2012].

The cytotoxicity of a multi-step extract (containing 26% carbohydrates, 21.3% phenolics, 12% uronic acids), at concentrations of between 1.9 and 2000 µg/mL, was tested in human A549 cells and mouse L929 fibroblasts. The extract showed no cytotoxic effects at concentrations up to 500 µg/mL. Concentrations of 1000 µg/mL and 2000 µg/mL resulted in a lower cell proliferation rate compared to control [Šutovská 2014].

An extract (not further specified) did not have a significant influence on the cell viability of blood platelets at a concentration range between 5 µg/mL and 100 µg/mL [Rywaniak 2015].

Helenalin and 11α,13-dihydrohelenalin were cytotoxic against GLC_4 (a human small cell bronchial carcinoma cell line) and COLO 320 (a human colorectal cancer line). IC_{50} values for helenalin were 0.44 µM against GLC_4 and 1.0 µM against COLO 320; corresponding values for 11α,13-dihydrohelenalin were 66.1 and 64.7 µM, compared to 4.6 and 8.8 µM for the reference compound cisplatin. Most flavonoids in arnica flower had low cytotoxic activity at 200 µM [Woerdenbag 1994; Anon 2001]. Isolated flavonoids from arnica flower, applied to human bronchial carcinoma cell lines, effectively reduced the cytotoxic activity of helenalin [Woerdenbag 1995]. Inhibition of cellular respiration of Ehrlich ascites cells was reported [Hall 1978]. Helenalin and 11,13-dihydrohelenalin, as well as an unspecified extract, inhibited platelet activation [Weil 1988; Schröder 1990].

The effects of 2β-ethoxy-6-O-acetyl-2,3-dihydrohelenalin on IL-8 were studied in HeLa229 cells, with parthenolide as positive control. The compound suppressed IL-8 production at low concentrations (IC_{50}=4.61µM) [Kos 2005].

A β-cyclodextrin-helenalin complex was studied in T47D breast cancer cells using the MTT assay. After 24, 48 and 72 hours, a dose- and time-dependent cytotoxicity with IC_{50} values of 2.1 nM, 1.64 nM and 1.4 nM was observed. The inhibitory effect of the complex on telomerase gene expression in a T47D cell line was investigated by qRT-PCR, which showed that the complex dose-dependently decreased hTERT gene expression in treated cells compared to control [Samaneh 2013].

In THP-1 and Jurkat cells, as well as in PBMC, a dose-dependent cytotoxicity of helenalin was demonstrated with IC_{50} values of 1.1 µM, 1.2 µM and 0.2 µM respectively [Zwicker 2017].

Anti-platelet effect
Pre-incubation with an extract rich in phenolic acids (not further specified), at concentrations of 7.5 µg/mL and 15 µg/mL, significantly ($p<0.05$) reduced ADP-induced aggregation in whole blood and platelet-rich plasma, decreased the platelets' reactivity index in whole blood and showed antioxidant capacity [Rywaniak 2015].

Other effects
Aqueous extracts (2 mg/ml of dried plant extract redissolved after lyophilisation) had an antihistamine effect on smooth muscle preparations [Brunelin-Geray 1969].

An ethanolic extract (25:1) and eight isolated sesquiterpene lactones were evaluated for heat shock protein 70 (HSP-70)-inducing activity, cytotoxicity, melanin production, and production and expression of tyrosinase in B16 cells. The extract was active in inducing HSP70, with low cytotoxicity. Within 9 h, a significant ($p<0.05$) up-regulation of the expression of HSP70 by helenalin 2-methylbutyrate (AM-2) and the extract was shown. An upward band-shift of heat shock factor-1 was observed in cells treated with AM-2 or the extract. Pre-treatment of the cells with AM-2 or the extract significantly ($p<0.05$) supressed the increase of melanin caused by 3-isobutyl-1-methylxanthine and lead to a decrease of tyrosinase [Usui 2015].

Ex vivo experiments
Airway smooth muscle reactivity was examined using tracheal smooth muscle strips from guinea pigs treated with a multi-step extract containing 26% carbohydrates and 21.3% phenolics (100 mg/kg), salbutamol (10 mg/kg i.p.; positive control group) or water (2 mL/kg; negative control group). The extract concentration-dependently significantly ($p<0.01$ to $p<0.05$) attenuated acetylcholine- and histamine-induced contractions in comparison to the negative control. Furthermore, relaxation of isolated tracheal smooth muscle strips after treatment with the extract was similar to the positive control [Šutovská 2014].

In vivo experiments

Anti-inflammatory effects
Rats with ulcerative mouth lesions induced by 40% sodium hydroxide were treated topically with either a tincture (30% concentration, starting material not quantified; n=25) or a saline control (n=25). The arnica treated group exhibited faster re-epithelialization than the control group, and the number of blood vessels was higher in the treatment group on days 2, 7, 14, 21 and 42 (significance data not provided). The number of lymphocytes in the arnica-treated rats was significantly ($p<0.05$) lower on day 42 than day 2 [Sawada 2016].

In rats with collagen-induced arthritis, oral treatment with a methanolic extract (yield 10.85%) at 75 mg/kg b.w. resulted in a significant ($p<0.001$) reduction in the severity of arthritis and a significantly ($p<0.0001$) attenuated arthritic index as compared to untreated arthritic rats. Behavioural tests such as the open field test showed significantly ($p<0.0001$) improved locomotor and exploratory behaviour and a significantly ($p<0.0001$) increased motility score in comparison with the untreated arthritic rats. Pro-inflammatory cytokines were significantly ($p<0.0001$) downregulated to the baseline of healthy controls in comparison to the untreated arthritic rats [Sharma 2016].

Intraperitoneal pre-treatment with helenalin at 2.5 mg/kg b.w. significantly ($p<0.001$) inhibited carrageenan-induced rat paw

oedema [Hall 1979]. In mice, helenalin (20 mg/kg b.w. i.p.) significantly ($p<0.001$) inhibited the acetic acid-induced writhing reflex by 93% [Hall 1979].

Intraperitoneal treatment of rats with chronic adjuvant arthritis with helenalin at 2.5 mg/kg/day for 3 weeks confirmed that sesquiterpene lactones are the constituents mainly responsible for anti-inflammatory activity [Hall 1980]. 11α,13-Dihydrohelenalin acetate and methacrylate applied topically at 1 µmol/cm^2 inhibited croton oil-induced mouse ear oedema by 54 and 77% respectively ($p<0.001$), compared to 44% inhibition by indometacin at 0.2 µmol/cm^2 [Klaas 2002].

At a dose of 1 µmol/cm^2, 2β-ethoxy-6-O-acetyl-2,3-dihydrohelenalin induced a 42% inhibition of croton oil-induced mouse ear oedema [Kos 2005].

Tumour-inhibiting activity
Sesquiterpene lactones from arnica flower inhibited the growth of Ehrlich ascites in mice and Walker 256 carcinosarcoma in rats [Hall 1978].

Antimicrobial activity
The effects of helenalin on *Staphylococcus aureus* infection were investigated in the mammary glands of lactating mice. Helenalin (20 mg/kg i.p.) was administered at both 9 and 3 hours prior to infection of the mammary glands with *S. aureus*. Examination after 12 hours showed that helenalin reduced bacterial proliferation and significantly ($p<0.05$) reduced leukocyte infiltration in the mammary glands when compared to control (DMSO) [Boulanger 2007].

Bronchodilatory effects
The bronchodilatory and antitussive effects of a multi-step extract containing 26% carbohydrates and 21.3% phenolics were tested in guinea pigs exposed to a citric acid aerosol. The animals were divided into six groups, three test groups received either 50 mg/kg, 75 mg/kg or 100 mg/kg p.o. of the extract, positive control groups received either codeine (10mg/kg p.o.) or salbutamol (10mg/kg i.p.) and the negative control group received water (2 mL/kg). All extract doses produced a significant cough-suppressive effect after 120 minutes ($p<0.01$) and 300 minutes (50 and 75 mg/kg $p<0.01$; 100mg/kg $p<0.05$). This antitussive effect was not dose-dependent and was lower than that of the positive control codeine ($p<0.001$ at 120 mins, $p<0.01$ at 300 mins). However citric-acid induced bronchial smooth muscle reactivity was significantly ($p<0.05$ to $p<0.01$) reduced by the extract compared to negative control (water) in a dose-dependent manner; while at 300 minutes the extract demonstrated significantly greater activity (75 mg/kg $p<0.01$; 100 mg/kg $p<0.001$) than the positive control group (salbutamol) [Šutovská 2014].

Pharmacological studies in humans
In a randomized, double-blind, placebo-controlled trial, the effectiveness of an arnica gel on pain, indicators of inflammation, muscle damage and improvement of performance was tested in 20 well-trained sportmen who undertook an exercise protocol designed to induce delayed onset muscle soreness (DOMS) and muscle damage. Each 1 g of gel contained arnica tincture equivalent to 10 mg of dry flower. The arnica gel or an identical placebo gel were applied (2.5 g to an approximate diameter of 2 cm) immediately after completing the exercise and every 4 waking hours for 4 days. The outcome was measured with a VAS, a Somedic algometer, an isokinetic dynamometer, as well as by determination of IL-1β, IL-6, TNF-α, C-reactive protein, myoglobin and creatinine kinase. Application of the arnica gel led to significantly ($p=0.045$) less pain in the quadriceps, 72 hours after the exercise, when compared to the placebo gel. Muscle tenderness was significantly ($p<0.05$) lower in the arnica group when compared to placebo, at 72 hours post-exercise in the quadriceps muscle, and at various time points in the gastrocnemius muscle (immediately after, and 4, 24 and 72 hours after). There were no significant differences between the groups in any of the inflammatory or muscle damage markers [Pumpa 2014].

Clinical studies

Varicosis
In a randomized, double-blind, placebo-controlled study, patients with chronic venous insufficiency received basic hydrotherapy treatment in addition to topical application to the lower legs and feet with either an extract ointment (n = 39) or a placebo ointment (n = 39). After 3 weeks treatment, from objective plethysmographic measurements and subjective assessments (feelings of tension and swelling in the legs, pain in the legs), improvements were observed in both groups but the degree of improvement was greater after verum treatment. A further study in 100 patients (verum 50, placebo 50), under identical conditions except using an extract gel, showed comparable improvements but no difference between groups [Brock 2000].

Osteoarthritis
A six week, open, multicentre trial investigated the efficacy of a gel containing 50% tincture (1:20; 50% ethanol m/m) in 79 patients (ITT population) with mild to moderate osteoarthritis of the knee. Fifty four patients completed the study (PP population). The gel was applied twice daily as a thin layer on the affected knee. The patients assessed effectiveness with the WOMAC Score and a five-point-scale for subjective assessment. After 3 weeks the WOMAC Score was significantly ($p<0.0001$) reduced by 6.0 points in the ITT population and 7.4 points in the PP population; after 6 weeks it was significantly ($p<0.0001$) lowered by around 8.5 points (ITT) and 10.5 points (PP). Efficacy of the gel was stated as being "very good" or "good" in 52% (ITT) and 63% (PP), and as having "no effect" in 13% (ITT) and 11% (PP) [Knuesel 2002].

A randomized, double blind study in 198 patients with hand osteoarthritis (ITT), of which 174 completed the study (PP), investigated the effect of topical treatment with the same gel in comparison to ibuprofen gel (5%), applied 3 times daily for 3 weeks. Reduction of pain was recorded on VAS (100 mm) and functional capacity of the hand was validated with the Hand Algofunctional Index (HAI). There was almost no difference between the Arnica and the ibuprofen gel from the 1st to the 21st day in the VAS (-26.6 points to -23.9 points) as well as in the HAI (-4.3 points to -4.6 points). "Very good" or "good" efficacy was stated by 64% of the arnica group and by 58.8% of the ibuprofen group, while global efficacy evaluation by physicians was "very good" or "good" in 56.5% (ibuprofen) and 64.0% (arnica) [Widrig 2007].

A randomized, double-blind, controlled, multi-centre study compared the efficacy of an arnica gel (50 g fresh herbal tincture (1:20) / 100 g gel) with an ibuprofen (5%) gel for osteoarthritis of the hands in 204 patients. The gels (4 cm strip) were applied 3 times daily for 3 weeks. The effects of the arnica gel were comparable to the ibuprofen gel, regarding hand functional capacity, pain intensity, number of painful joints, duration and severity of morning stiffness and paracetamol consumption, in a clinically relevant manner [Ross 2008].

Bruises and ecchymosis
A randomized, double-blind, placebo-controlled trial investigated the efficacy of an ointment (30% of a tincture,

1:10) used after bilateral upper blepharoplasty in 116 patients. The patients applied the ointment or placebo twice daily on one periorbital area, the untreated contralateral side served as a control. The primary outcome measure was the appearance of the periorbital areas based on light photography, as assessed by a medical and nonmedical panel after 3 days, 7 days and 6 weeks. The secondary outcome measures were the degrees of ecchymosis, erythema and swelling, assessed by light photography, pain and patient satisfaction using a VAS. No significant ($p>0.05$) differences between verum and placebo were observed at any of the time points [van Exsel 2016].

In a randomized, double-blind, placebo-controlled study, the effect of a gel (not further specified) on the bruises of nineteen patients with facial telangiectasia was tested both pre- and post-treatment with a 585 nm pulsed dye laser. The pre-treatment group (n=9) applied the gel to one side of the face and vehicle to the other side, twice a day for two weeks prior to laser treatment; the post-treatment group (n=10) used the same application for 2 weeks after the laser treatment. On days 0, 3, 7, 10, 14 and 17 bruising was assessed using a VAS by the patient and the physician. No significant differences between the mean scores of verum and vehicle were seen in either group [Alonso 2002].

A randomized, controlled, prospective clinical trial in patients who had undergone an open technique rhinoplasty, compared the effect of topical treatment with a cream (not further specified; n=36) applied four times a day for 10 days, with no post-operative treatment (n=36), on the regression of postoperative peri-orbital oedema and ecchymosis. According to a 4 point scale (ranging from 0 to 4), on postoperative days 1, 5 and 7, ecchymosis was significantly ($p<0.005$) less after verum, and regression of the oedema was significantly ($p<0.005$) faster than in the control group [Simsek 2016].

Lesions of the oral mucosa
Male and female individuals (n=21) with recurrent ulcers of the oral mucosa (more than four episodes per year) received an ointment containing 30% of a tincture, the control group (n=10) received placebo. The ointment was applied three times a day after oral hygiene on the ulcer. 52% of the patients of the verum group perceived a faster ulcer lesion healing process in the oral mucosa, and 45% reported an analgesic effect, as compared to placebo [Mendes 2008].

Pharmacokinetic properties
No data available.

Preclinical safety data
The safety of arnica flower has been assessed in a review. In general, extracts have been found to have low toxicity in acute tests in mice, rats and rabbits. They were not irritating, sensitizing or phototoxic to mouse or guinea pig skin, and did not produce significant ocular irritation [Anon 2001].

The safety profile of arnica flower has also been reviewed with respect to sesquiterpene lactones, flavonoids and pyrrolizidine alkaloids [Merfort 1992a; Hausen 1997]. The pyrrolizidine alkaloids tussilagine and isotussilagine [Paßreiter 1992a, 1992b] are considered non-toxic because they lack the key structure, a 1,2-unsaturated necine group, considered to be responsible for the toxicity of certain pyrrolizidine alkaloids [Merfort 1992a; Paßreiter 1992b].

Acute toxicity
The oral LD_{50} of an extract (not further specified) in rats has been reported as > 5g/kg. In mice, oral and intraperitoneal values of an extract have been reported as 123 mg/kg and 31 mg/kg respectively [Anon 2001].

LD_{50} values of helenalin were determined as 150 mg/kg b.w. in mice, 125 mg/kg in rats, 90 mg/kg in rabbits and 85 mg/kg in hamsters, and estimated as 100-125 mg/kg in sheep [Witzel 1976].

Mutagenicity
In the Ames mutagenicity test, a hydroethanolic extract showed a weak mutagenic potential in *Salmonella typhimurium* strain TA98 with or without S9 activation and in strain TA100 with activation; the effects were possibly due to the flavonoids present in the extract [Göggelmann 1986]. Helenalin showed no mutagenic potential in the Ames test using *Salmonella typhimurium* strains TA98, TA100, TA1535 and TA1537, but was relatively toxic to the test organisms [MacGregor 1977].

Genotoxicity
Helenalin (dose not further specified) was tested for genotoxicity using six strains of *Bacillus subtilis* (rec A8, rec E4, mc-1, Exc-strain, hcr-9 and strain fh 2006-7). It produced lethal DNA damage in strains mc-1 and rec E4 in the spot assays. Exposure of the fractional survival of *B. subtilis* strains to increasing concentrations of helenalin (1-1000 µg) demonstrated a significant ($p<0.05$) decrease in the survival of the repair-deficient strains [Jones 1981].

Chronic toxicity
The effect of a hydroethanolic extract (25 mg/kg/day p.o.; not further specified) on male and female albino rabbits for three months was investigated. In the male test group, all measured blood parameters were significantly ($p<0.05$) elevated, whereas they were significantly ($p<0.05$) lowered in females, except platelet count which was elevated. Creatinine and uric acid levels were significantly ($p<0.05$) raised in female animals as compared to males. Cardiac enzymes were significantly ($p<0.05$) elevated in males and significantly ($p<0.05$) lowered in females. Males showed significantly ($p<0.05$) decreased lipid profile and liver enzyme parameters, whereas females exhibited significantly ($p<0.05$) raised lipid profile and liver enzymes levels. Urine volume and specific gravity were significantly ($p<0.05$) lowered in both male and female animals. Blood cells were observed in urine of female animals. No significant ($p>0.05$) toxic effects were observed on the stomach, kidney and liver tissues of male rabbits. In contrast, areas of myocytolysis in the right ventricular wall and inter-ventricular septum were observed in the heart tissues [Farah-Saeed 2016].

Allergenic activity
Tinctures from fresh flowers of Spanish (SP; 0.7 mg/mL 11α,13-dihydrohelenalin esters) or Central European (CE; 0.83 mg/mL helenalin esters) chemotypes and several isolated sesquiterpene lactones were investigated for their allergenic potential in the mouse ear swelling test. On day 0, mice were sensitized epicutaneously with the application to shaved abdominal skin of either 100 µl of 2,4,6- trinitrochlorobenzene (TCNB; 7% in acetone), undiluted SP or CE tinctures or the isolated sesquiterpene lactones 11α,13-dihydrohelenalinisobutyrate or 11α,13-dihydrohelenalinmethacrylate (2.12 and 21.1 mM; from SP) or helenalinisobutyrate (1.2 and 12 mM; from CE) in ethanol; while controls received acetone or ethanol. The mice were then challenged on day 5 with application to both ears of either 20µL of TNCB (1%), 20 µL of the tinctures or the sesquiterpene lactones. Ear thickness was measured prior to challenge and 24 hours later. TNCB induced a strong ear swelling, whereas neither the tinctures nor the sesquiterpene lactones induced ear swelling. Pre-treatment with the tinctures significantly ($p<0.05$) decreased the ear swelling response to TNCB in TNCB-sensitized mice. Sensitization was also induced with 50 µL of the undiluted tinctures on 3 consecutive days in CD4-depleted mice (treated i.p. with anti-CD4 monoclonal

antibody on the 3 days prior to sensitization and 4 days later). The ear challenge in this case was performed on days 5 and 6 with 25 µL tincture. Here the CE but not the SP tincture, induced contact hypersensitivity [Lass 2008].

Clinical safety data

Allergenic potential
The allergic potential of a standard arnica patch test (extract) compared with 6 different arnica preparations (two extracts, tincture, gel, ointment, oil) containing various quantities of sesquiterpene lactones, a standard sesquiterpene lactone mix, 3 isolated sesquiterpene lactones and vehicles-only (gel and ointment base) was investigated in eight patients with a history of a positive standard arnica patch test within the previous 2 years. One patient showed positive reactions to each of the arnica preparations, while three patients showed positive patch tests to 1, 2 or 3 of the 6 test preparations and one patient showed no reaction to the test preparations. None of the patients that tested positive to the standard Arnica patch test displayed positive reactions to the individual isolated sesquiterpene lactones [Jocher 2009].

In a six week, open, multicentre trial patients (n=79) applied a gel (50% tincture, 1:20; ethanol 50% m/m) twice a day for 6 weeks. Six patients experienced mild or moderate local reactions at the treatment site, which consisted of red spots and itching, a localized rash, dry skin, pruritus or petechiae that disappeared after treatment with corticosteroid ointment [Knuesel 2002].

A randomized, double blind study involving 198 patients investigated the effect of a gel (50% tincture, 1:20; ethanol 50% m/m) for topical treatment of hand osteoarthritis in comparison to ibuprofen gel (5%) for 3 weeks. Treatment-related adverse events on the skin were recorded in 6.1% and 4.8% of patients on ibuprofen and arnica respectively [Widrig 2007].

Application of an ointment (30% tincture, 1:10) twice daily for six weeks to one periorbital area after bilateral upper blepharoplasty in 136 patients, produced no adverse drug reactions [van Exsel 2016].

In a randomized, double-blind, placebo-controlled study, patients with facial telangiectasia (n=19) applied a gel (not further specified) twice daily for two weeks before or after laser treatment on the bruises. No side effects from verum or vehicle gel were reported [Alonso 2002].

In a randomized, double-blind, placebo-controlled trial, topical application of a gel by 10 well-trained sportsmen for 4 days after intense excessive exercise did not show any adverse effects [Pumpa 2014].

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

BALLOTAE NIGRAE HERBA 2015

Black Horehound

DEFINITION

Black horehound consists of the dried flowering tops of *Ballota nigra* L. It contains not less than 1.5 per cent of total *ortho*-dihydroxycinnamic acid derivatives, expressed as acteoside ($C_{29}H_{36}O_{15}$; M_r 624.6) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Black horehound].

CONSTITUENTS

The main characteristic constituents are: phenylpropanoids (ca. 5.5%) including the *ortho*-dihydroxycinnamic acid glycosides acteoside (verbascoside), forsythoside B, arenarioside [Seidel 1996a], ballotetroside [Seidel 1997] and martynoside [Tóth 2007], and non-glycosidic (+)-*E*-caffeoyl-L-malic acid [Didry 1999]; flavonoids, mainly derivatives of luteolin and apigenin, e.g. luteolin 7-lactate and 7-glucosyl-lactate [Bertand 2000], apigenin 7-*O*-glucoside and apigenin 6,8-*C*-diglucoside (vicenin 2) [Darbour 1986]; and labdane diterpene lactones [Savona 1976; Savona 1977a; Savona 1977b; Seidel 1996b].

CLINICAL PARTICULARS

Therapeutic indications
Tenseness, restlessness and irritability with difficulty in falling asleep [Huriez 1991; Hänsel 1992].

Black horehound has also been documented for the relief of mild spasmodic gastric complaints [Hänsel 1992].

Posology and method of administration

Dosage

Adult single dose: 1.5-5 g of the drug (e.g. as a tea infusion) or equivalent preparations prepared with water or ethanol (maximum 45% V/V) [Huriez 1991; Ballota; Tisanes].

Elderly: as for adults.

Children from 3 to 12 years under medical supervision only: proportion of adult dose according to body weight, as non-alcoholic preparations.

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contra-indications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
Due to the sedative effects of black horehound, the ability to drive or use machines might be affected.

E/S/C/O/P MONOGRAPHS

Undesirable effects
None reported.

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Receptor-binding activity
The competitive receptor binding activity of four phenylpropanoid glycosides, acteoside, forsythoside B, arenarioside and ballotetroside, and the non-glycosidic phenylpropanoid caffeoyl-L-malic acid, has been studied. Apart from ballotetroside, they showed affinity for benzodiazepine, dopaminergic and morphinic receptors isolated from rat brain with IC_{50} values between 0.4 mg/ml and 4.8 mg/ml [Daels-Rakotoarison 2000].

Antioxidant effects
A 75%-ethanolic extract from *Ballota nigra* subsp. *anatolica* inhibited the formation of superoxide anion with an IC_{50} of 0.74 mg/ml [Citoglu 2004].

An aqueous dry extract from black horehound showed a concentration-dependent activity in the DDPH assay (IC_{25} = 4.81 µg/ml), concentration-dependent superoxide radical scavenging activity using the xanthine/xanthine oxidase system (IC_{25} = 14.6 µg/ml) and NO radical scavenging activity (IC_{25} = 122 µg/ml) [Vrchovská, 2007].

The antioxidant activity of five phenylpropanoids (acteoside, forsythoside B, arenarioside, ballotetroside, and caffeoyl-L-malic acid) was investigated against the reactive oxygen species (ROS) superoxide anion, hydrogen peroxide, hypochlorous acid and hydroxyl radical. These phenylpropanoids exhibited ability to scavenge ROS with IC_{50} values comparable to that of *N*-acetylcysteine. Furthermore, they significantly and dose-dependently inhibited the release of ROS from isolated and stimulated polymorphonuclear neutrophils from human blood ($p<0.05$), with activity in the order acteoside > forsythoside B > caffeoyl-L-malic acid > arenarioside > ballotetroside. Proteine kinase C or phospholipase C pathways are involved in the mechanism of action [Daels-Rakotoarison 2000].

Five phenylpropanoids from black horehound were evaluated for their ability to inhibit Cu^{2+}-induced peroxidation of human LDL. They strongly inhibited peroxidation of LDL in a dose-dependent manner with ED_{50} values of 1 µM for acteoside and forsythoside B, 1.8 µM for arenarioside, 7.5 µM for ballotetroside and 9.5 µM for caffeoyl-L-malic acid, compared to 2.3 µM for quercetin. The capacity of phenylpropanoids to inhibit Cu^{2+}-induced LDL oxidation is linked to their free radical scavenging properties [Seidel 2000].

Antimicrobial activity
An aqueous dry extract from black horehound dose-dependently inhibited the formation of biofilm of MRSA with an IC_{50} of 8 µg/ml [Quave 2008].

Acteoside, forsythoside B and arenarioside, but not ballotetroside or caffeoyl-L-malic acid, exhibited moderate antibacterial activity against *Staphylococcus aureus* (Gram-positive) and *Proteus mirabilis* (Gram-negative) at a concentration of 128 µg/ml [Didry 1999].

In vivo experiments

Sedative and antidepressive effects
The psychotropic effects of a black horehound aqueous dry extract, intraperitoneally administered to rodents, were evaluated from a range of tests. A dose of 200 mg/kg b.w. significantly reduced mobility and, to a lesser extent, curiosity in mice; produced a significant tranquillizing effect in mice; significantly reduced anxiety but not locomotor activity in rats; and significantly prolonged barbiturate-induced sleeping time in rats. No muscle relaxant effects were evident in mice from doses of 200 or 400 mg/kg [Mongold 1991].

After i.p. administration to mice at 0.5 ml per animal a 10% aqueous extract from black horehound had a marked sedative effect on the central nervous system, reducing spontaneous motor activity by 60% after 1 hour and 65% after 3 hours [Rácz-Kotilla 1980].

After i.p. administration to rats an aqueous dry extract from black horehound showed significant antidepressant activity in the forced swimming test. Mean durations of immobility were 570 seconds for untreated control animals, 496 seconds after the extract at 240 mg/kg ($p<0.001$) and 379 seconds after amitriptyline at 5 mg/kg i.p. ($p<0.001$). This extract did not exert significant anxiolytic activity in the elevated plus-maze test [Vural 1996].

Hypoglycaemic effects
Oral administration of a 70%-ethanolic dry extract from black horehound to rats at 400 mg/kg b.w. daily for 7 days caused significant decreases in blood glucose and total serum cholesterol (both $p<0.01$). In the glucose tolerance test in rats, a single oral dose of the same extract at 400 mg/kg significantly reduced blood glucose levels ($p<0.001$) and increased serum insulin levels ($p<0.01$) within 15 minutes [Nusier 2007a].

In a further experiment with the same extract, a single oral dose at 400 mg/kg significantly reduced plasma glucose levels in healthy normoglycaemic rats by 32% and in alloxan-induced diabetic rats by 22% (both $p<0.001$) after 6 hours. At this dose level no significant changes were observed in spontaneous motor activity of the animals, nor noticeable changes in behaviour and intake of food and water [Nusier 2007b].

Clinical studies
In an open study, 28 patients with general anxiety disorder, diagnosed in accordance with the DSM (at least 6 of the 18 criteria comprising the DSM III R classification) and involving depression and sleep disorders, were treated daily for 90 days with 3 × 5 ml of a black horehound liquid preparation (14% ethanol, corresponding to 3 × 0.5 g of black horehound). Based on clinical examination and DSM III R assessment, responder rates after 60 and 90 days were 65 and 73% of patients respectively. Patients with sleep disorders showed particularly marked improvement. Out of 10 patients taking benzodiazepines prior to the study, 3 discontinued and 4 reduced their dose by half [Huriez 1991].

Pharmacokinetic properties
No data available.

Preclinical safety data

Acute toxicity
After administration of a single large dose of a black horehound aqueous dry extract to mice at 2 g/kg b.w. no mortality occurred and no signs of toxicity were evident over a period of 15 days or from post-mortem examination [Mongold 1991].

Clinical safety data

In an open clinical study, no major adverse effects were reported after treatment of 28 patients with 3 × 5 ml of a black horehound liquid preparation (14% ethanol, corresponding to 3 × 0.5 g black horehound) for 90 days. Feelings of fatigue, which diminished as the study progressed, and nausea, which was alleviated by taking the black horehound preparation after meals, were reported [Huriez 1991].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

BETULAE FOLIUM

2015

Birch Leaf

DEFINITION

Birch leaf consists of the whole or fragmented dried leaves of *Betula pendula* Roth and/or *Betula pubescens* Ehrh. as well as hybrids of both species. It contains not less than 1.5 per cent of flavonoids, calculated as hyperoside ($C_{21}H_{20}O_{12}$; M_r 464.4) with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Birch Leaf].

Fresh material may also be used, provided that when dried it complies with the monograph of the European Pharmacopoeia.

CONSTITUENTS

1-3% of flavonol glycosides, principally hyperoside and other quercetin glycosides together with glycosides of myricetin and kaempferol [Tissut 1972; Pawlowska 1982; Pokhilo 1983; Dallenbach-Tölke 1986; 1987a; 1987b; Keinänen 1996; Ossipov 1996; Hänsel 2010, Raal 2015]; other phenolic compounds including 3,4′-dihydroxypropiophenone 3-glucoside (ca. 0.8% in *B. pendula*, 0.08% in *B. pubescens*) and chlorogenic acid (ca. 2% in *B. pubescens*, 0.02-0.1% in *B. pendula*) [Keinänen 1996; Ossipov 1996]; triterpene alcohols of dammarane type and their malonyl esters [Pokhilo 1983, 1986, 1988; Baranov 1983; Rickling 1992, 1993; Hilpisch 1997].

Other constituents include monoterpene glucosides [Tschesche 1977], a sesquiterpene oxide [Pokhilo 1984], roseoside [Tschesche 1976], tannins, traces of essential oil [Hänsel 2010, Orav 2011] and approx. 4% of minerals, particularly potassium [Szentmihályi 1998, Hänsel 2010].

Fresh leaves contain up to 0.5% of ascorbic acid [Jones 1984].

CLINICAL PARTICULARS

Therapeutic indications
Irrigation of the urinary tract, especially in cases of inflammation and renal gravel, and as an adjuvant in the treatment of bacterial infections of the urinary tract [Schilcher 1984, 1987; Hänsel 2010].

Posology and method of administration

Dosage
2-3 g of dried leaf as an infusion, three to four [Gorecki 2013] times daily; equivalent preparations [Schilcher 1987; Schilcher 1990].

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contra-indications
None known.

Special warnings and special precautions for use
Oedema due to impaired heart and kidney function [Schilcher 1987].

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

E/S/C/O/P
MONOGRAPHS

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Diuretic activity
Various flavonoids were investigated for their inhibitory activity on specific neuropeptide hydrolases which regulate the formation of urine through excretion of sodium ions [Borman 2000]. The results led to the conclusion that certain flavonoids, especially quercetin, and other phenolic compounds present in birch may contribute to accelerated formation of urine [Melzig 2000].

Anti-inflammatory effect
An aqueous extract (0.63 mg/mL) was tested for its anti-proliferative effect on human peripheral blood mononuclear cells, activated with anti-CD3/CD28 monoclonal antibodies. In the highest tested concentration (160 µg/mL) the optical density (OD) was reduced from 0.54 ±0.1 in untreated cells to 0.18 ±0.03. Methotrexate as a positive control reduced the OD to 0.25 ±0.09 at a concentration of 1 mg/mL. The extract had no effect on the proliferation of resting cells [Gründemann 2011].

Antioxidant effect
A dry extract (ethanol 70%; mass/volume ratio 1:10) was tested for its Trolox Equivalent (TE) antioxidative capacity. The constituents hyperoside and chlorogenic acid showed the strongest activity with 28.9 µmol TE/g and 22.8 µmol TE/g respectively [Raudone 2014].

In vivo experiments

Diuretic effect
After oral administration of an infusion of birch leaf to rabbits, urine volume increased by 30% and chloride excretion by 48% [Vollmer 1937]; in mice, urine volume increased by 42% and chloride excretion by 128% [Vollmer 1937]. Young birch leaves administered orally to mice and rats did not produce these effects, in fact an anti-diuretic action was apparent [Elbanowska 1966].

Oral administration of powdered birch leaf to dogs at 240 mg/kg b.w. increased urine volume by 13.8% after 2 hours; a flavonoid fraction at 14 mg/kg increased urine volume by 2.8% [Borkowski 1960].

Further studies in rats showed increased excretion of urine after oral administration of aqueous and alcoholic extracts rich in flavonoids (48, 76 and 148 mg/100 mL). The aquaretic effect correlated with the amount of flavonoids, but no saluretic effect could be demonstrated [Schilcher 1987; Schilcher 1988; Schilcher 1989].

However, diuretic effects do not appear to be due entirely to flavonoids since lesser effects were achieved with isolated flavonoid fractions [Schilcher 1984; Schilcher 1990; Borkowski 1960; Schilcher 1988; Schilcher 1989; Lübben 1982].

Various extracts from birch leaf were administered orally to rats: an extract prepared with ethanol 70% (43 mg flavonoids/kg b.w.), a fraction obtained from this extract with butanol (192 mg flavonoids/kg b.w.), a butanolic fraction low in flavonoids (14 mg flavonoids/kg b.w.) and the aqueous residue from the separation process (0.7 mg flavonoids/kg b.w.). No increase in diuresis or saluresis could be demonstrated for any of these preparations [Rickling 1992].

It has been suggested that the potassium content of birch leaf may contribute to the diuretic effect [Schilcher 1987; Schilcher 1990; Schilcher 1988; Schilcher 1989]. High potassium-sodium ratios were determined in dried leaf (189:1) and in a 1% decoction (168:1) [Szentmihályi 1998].

Gastroprotective effect
The gastroprotective effects of a dried methanolic (70%; not further specified) extract were investigated in rats with ethanol-induced (90%) gastric ulcers. Pre-treatment with doses of 100, 200 and 400 mg/kg b.w. demonstrated dose-dependent reductions in the lesions. Pre-treatment at the highest dose significantly reduced alcohol-induced lesions by 71.4% ($p<0.01$) compared to the positive control misoprostol at 0.50 mg kg^{-1} (85.7%) [Germano 2013].

Clinical studies
In a field study, 1066 patients received a dry aqueous extract of birch leaf (4-8:1) at various daily doses (from 180 mg to 1080 mg or more daily) for irrigation of the urinary tract. In most cases (63%) the treatment period was 2-4 weeks. The patients could be classified into four groups: 73.8% suffered from urinary tract infections, cystitis or other inflammatory complaints, 14.2% from irritable bladder, 9.3% from stones and 2.7% from miscellaneous complaints. In the first group 56% of patients also received antibiotic therapy. After treatment the symptoms disappeared in 78% of patients in the first group, 65% in the second group and 65% in the third group. Symptoms disappeared in 80% of patients treated with, and in 75% of those going without, antibiotics. Both physicians and patients considered efficacy to be very good (39% and 48% respectively) or good (52% and 44% respectively) [Müller 1999].

In a randomized, double-blind, placebo-controlled pilot study, 15 patients with infections of the lower urinary tract were treated with 4 cups of birch leaf tea or placebo tea daily for 20 days. Microbial counts in the urine of the birch leaf tea group decreased by 39% compared to 18% in the control group. At the end of the study, 3 out of 7 patients in the verum group and 1 out of 6 in the placebo group no longer suffered from a urinary tract infection [Engesser 1998].

Pharmacokinetic properties
No data available.

Preclinical safety data
An extract of birch leaf gave a very weak mutagenic response in the Ames test [Göggelmann 1986]; no other studies have been performed to confirm this.

Clinical safety data
In an open post-marketing study, mild adverse effects were reported in only 8 out of 1066 patients who received a dry aqueous extract of birch leaf (4-8:1) at daily doses of up to 1080 mg for 2-4 weeks [Müller 1999].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

CALENDULAE FLOS

2019

Calendula flower

DEFINITION

Calendula flower consists of the whole or cut, dried, fully opened flowers, which have been detached from the receptacle, of the cultivated, double-flowered varieties of *Calendula officinalis* L. It contains not less than 0.4 per cent of flavonoids, calculated as hyperoside ($C_{21}H_{20}O_{12}$, Mr 464.4) with reference to the dried drug [Calendula flower, Ph. Eur.].

The material complies with the monograph of the European Pharmacopoeia [Calendula flower, Ph. Eur.].

Fresh material may also be used, provided that when dried it complies with the monograph of the European Pharmacopoeia [Calendula flower, Ph. Eur.].

CONSTITUENTS

Triterpene saponins (2-10%), mainly oleanolic acid glycosides; free and esterified triterpene alcohols, especially faradiol 3-mono- and diesters, carotenoids (up to 3%), flavonoids (0.3-0.8%) based on quercetin and isorhamnetin, polysaccharides e.g. of the rhamnogalacturonan I type, sterols, sesquiterpenoids, phenolcarbonic acids, fatty acids, tocopherols and essential oil (0.2-0.3%) with α-cadinol and δ-cadinen as major components [Scheffer 1979, Komissarenko 1988, Varljen 1989, Vidal-Ollivier 1989a, Vidal-Ollivier 1989b, Isaac 1992, Della Loggia 1994, Akihisa 1996, Gracza1987, Zitterl-Eglseer 1997, Marukami 2001, Mukhtar 2004, Kishimoto 2005, Naved 2005, Petrovic 2011, Korzh 2012, Ollenikov 2013, Ollenikov 2014, D´Ambrosio 2015, Isaac 2017, Mohamed 2015, Caamal-Herrera 2016, Khidoyatova 2016, Lichius 2016, Miguel 2016, Nicolaus 2016].

CLINICAL PARTICULARS

Therapeutic indications
Treatment of minor inflammations of the skin and mucosa; as an aid to the healing of minor wounds [Scheffer 1979, Lichius 2016, Willuhn 1992, Duran 2005, Amoian 2010].

Posology and method of administration

Dosage

External use
Infusion for topical application: 1-2 g of dried flower per 150 mL of water.
Fluid extract 1:1-2.2 in 40-50% ethanol or tincture 1:5 in 70-90% ethanol [Isaac 2015]. For the treatment of wounds the tincture is applied undiluted; for compresses the tincture is usually diluted at least 1:3 with freshly boiled water [Willuhn 1992, Van Hellemont 1988].
Semi-solid preparations containing 2-10% of fluid extract 1:1 [Willuhn 1992, Isaac 2017, Farmacopoea Italiana].

Method of administration
For topical application.

Duration of administration
No restriction.

Contra-indications
Known sensitivity to members of the Asteraceae (Compositae) family.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

E/S/C/O/P
MONOGRAPHS

Pregnancy and lactation
No data available.

However, there are no objections to external use during pregnancy and lactation.

Effects on ability to drive and use machines
Not relevant.

Undesirable effects
Rare cases of skin sensitisation have been shown [Reider 2001, Mailhol 2009], whereas no allergic reactions were observed in 16 Asteraceae-sensitive persons in a patch test with a 10% petroleum ether extract [Paulsen 2001].

Overdose
Not applicable.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Wound-healing effects
In a scratch assay with Swiss 3T3 albino mouse fibroblasts a hexane (DER 7.7:1) and an ethanolic (DER 5.2:1) extract at 10 µg/mL significantly ($p<0.05$) enhanced cell numbers by 64.35% and 70.53%, respectively, mainly by stimulating migration. Faradiol myristate and palmitate were shown to contribute partially to the effect [Fronza 2009].

The proliferation of endothelial progenitor cells (EPC) was significantly stimulated by an extract (prepared in phosphate buffered saline) at concentrations of 50, 500 and 1000 ng/mL ($p<0.005$, 0.05 and 0.05, respectively). The expression of molecules involved in EPC chemotaxis and adhesion (VCAM-1, VE-cadherin, ICAM-1, PECAM-1, P-selectin, Tie-2, CXCR4) and cell migration ability in a scratch assay were significantly increased with 1 µg/mL ($p<0.05$ for VCAM-1, $p<0.005$ for all other assays) [Iordache 2011].

A CO_2 extract (18.2% faradiol esters and 0.97% carotenes) at 5 µg/mL and 20 µg/mL led to significant re-epithelialisation after 48 h incubation in a scratch assay using human conjunctival WKD cells ($p<0.05$ and 0.01 respectively) [Arana 2015].

Proliferation of Vero cells was increased by a methanolic and a 20% methanolic extract (1 µg to 100 µg/mL); the effect of apolar extracts was less. Cell migration was stimulated by the extracts (100 µg/mL) in the order hexane > 20% methanol > dichloromethane; the methanolic extract was inactive [Un 2015].

A tincture (41% ethanol) at dilutions of 1:50 and 1:100 significantly increased proliferation of human dermal and human lung fibroblasts ($p<0.05$ and 0.01) via a phosphatidylinositol-3-kinase-dependent pathway. The growth of HeLa cells remained unchanged. Cell migration of both fibroblast cell lines was stimulated significantly ($p<0.05$) after 24 hours [Dinda 2015].

The proliferation of human dermal fibroblasts was significantly and dose-dependently increased by a 50% ethanolic extract (yield 32%) and a water fraction thereof, with the strongest effect of both at 100 µg/mL ($p<0.001$). At 100 µg/mL both extracts enhanced cell migration in a scratch assay ($p<0.01$ and 0.05, respectively). Expression of CTGF and α-SMA (markers of increased fibroblast activity and wound contraction) was induced by the extract ($p<0.01$) [Dinda 2016].

Cultivation of non-malignant human CCD16 fibroblasts with a decoction (not further specified) for 24 and 48 hours resulted in a gradual but not significant increase of their numbers, as compared to control, and in beneficial morphological changes of the cell structure [Wyganowska-Swiatkowska 2016].

Three extracts (n-hexane, DER 11:1; ethanol, 8.3:1; water, 10:1) were investigated to analyse molecular effects in the inflammatory phase of wound healing. In human immortalized keratinocytes, the n-hexane and the ethanolic extract at 50 µg/mL activated NF-κB and IL-8 at the transcriptional and the protein level. A dose-dependent inhibition of collagenase activity was observed for the ethanolic (62.5 to 500 µg/mL) and aqueous extracts (62.5 to 2500 µg/mL), significant at all tested doses ($p<0.001$). The content of soluble collagen in the supernatant of human primary fibroblasts was increased by the ethanolic extract at 50 µg/mL [Nicolaus 2017].

Immunomodulatory effects
A dry 70% ethanolic extract caused an inhibitory effect in the mitogen-induced lymphocyte proliferation assay. In the mixed lymphocyte reaction the extract showed stimulatory effects at 0.1-10 µg/mL, followed by inhibition at higher concentrations [Amirghofran 2000].

A dose-dependent (125-500 µg/mL) increase in the proliferation of peripheral blood lymphocytes was observed after treatment with an aqueous dry extract from Laser-irradiated Calendula flower. Cell cycle analysis revealed a re-entering of the lymphocytes into S phase [Jiménez-Medina 2006].

Isolated polysaccharides from calendula flower were found to stimulate phagocytosis of human granulocytes [Varljen 1989].

Antiviral and antimicrobial effects
A 70% alcoholic tincture had high virucidal activity against influenza viruses and a marked ability to suppress the growth of herpes simplex virus [Bogdanova 1970].

A dry extract (dichloromethane-methanol 1:1) exhibited anti-HIV activity in an MTT (dimethylthiazole-diphenyltetrazolium)-based assay. In the presence of 10-30 µg/mL of the extract, 90% inhibition of HIV-1 replication in acutely infected lymphocytic Molt-4 cells was observed. At concentrations of 500 µg/mL the extract suppressed cell fusion and protected uninfected Molt-4 cells against subsequent HIV-induced cytolysis caused by co-cultivation with persistently infected U-937/HIV-1 cells for up to 24 hours. The extract (50, 100 and 200 µg/mL) also caused marked dose- and time-dependent inhibition of HIV-1 reverse transcriptase activity by up to 85% in a cell-free system [Kalvatchev 1997].

Extracts from the flowers had trichomonacidal activity, which has been attributed to oxygenated terpenes [Gracza 1987].

Suture material after extraction of the unerupted maxilliary third molars was investigated for different microorganisms. After left molar extraction the patients (n=12) did not use any mouthwash, whereas after extraction of the right molar 15 days later patients used a mouthwash with 1% of a tincture or a 0.12% solution of chlorhexidine digluconate. The suture material was removed after 7 days and extracted. Dilution series of the extacts were grown on 5 different media. The mean number of colony forming units of aerobic, facultative anaerobic microorganisms and *Candida* ssp. as compared to control was reduced by the calendula mouthwash but to a lesser extent than by chlorhexidine [Faria 2011].

In the disc diffusion assay, a methanolic and an ethanolic

extract at 300 µg/disc showed antifungal activity against a panel of different fungi, comparable to the effect of 30 µg/disc of fluconazole as positive control. Growth inhibition of numerous Gram-positive and Gram-negative bacteria by the extracts was less than that found for ciprofloxacin (4.5 mg/disc) [Efstratiou 2012].

A significant inhibition of *Staphylococcus epidermidis*, *S. aureus* (both $p<0.001$) and *Propionibacterium acnes* ($p<0.01$) was seen after treatment with a methanolic extract (not further specified) when compared to control [Nand 2012].

An 80% methanolic extract inhibited *Leishmania major* promastigotes (IC_{50} = 108.2 µg/mL). The infection rate of macrophages with amastigotes after incubation with the extract and the parasite survival rate were significantly ($p<0.001$) lower as compared to untreated control [Nikmehr 2014].

Combination of cefotaxime with a methanolic extract led to a pronounced reduction of MICs due to synergistic or additive effects in 10 multiresistent *Klebsiella pneumoniae* isolates co-producing extended spectrum beta lactamase and AmpC beta lactamase. The extract and cefotaxime alone were active at much higher concentrations only [Shah 2015].

In a similar approach, the essential oil (15 µL/disc) exhibited antifungal effects against numerous *Candida* species which were more pronounced than that of 20 µg/disc of nystatin [Gazim 2008].

Oleanolic acid from calendula flower showed marked antibacterial activity against several bacteria, of which the Gram-positive were more susceptible than the Gram-negative [Szakiel 2008].

Antioxidant and radical scavenging effects
Extracts of differing polarities exhibited antioxidative effects on liposomal lipid peroxidation induced by Fe^{2+}/ascorbic acid. Marked activity was observed with ether, butanol and aqueous extracts. In combination with pro-oxidants, different antioxidative effects were obtained: with pyralene the butanol and aqueous extracts were most effective; with carbon tetrachloride the chloroform and ethyl acetate extracts showed the strongest activity. Combination of fullerenol with each extract resulted in a further decrease in lipid peroxidation [Popovic 1999, Popovic 2000].

DPPH and ABTS radicals were scavenged by an ethanolic extract with IC_{50} values of 100 and 6.5 µg/mL. In several other radical scavenging or antioxidant assays the IC_{50} values were much higher [Preethi 2006].

Antioxidant activity was shown for an extract prepared with propylene glycol/water (85:15). Respiratory burst in human polymorphonuclear leukocytes after incubation with L-arginine followed by stimulation with N-formyl-methionyl-leucyl-phenylalanine was significantly reduced at extract concentrations from 0.05 µg/mL to 1.6 µg/mL ($p<0.01$) and after phorbol-12-myristate-13-acetate (PMA) from 0.10 µg/mL to 1.6 µg/mL ($p<0.05$ to $p<0.01$) [Braga 2009].

A 50% ethanolic extract (yield 15.7%) resulted in IC_{50} values of 97.1 µg/mL, 350.0 µg/mL and 4.4 µg/mL in the DPPH, the lipid peroxidation and the xanthine/luminol/XOD assay, respectively [Fonseca 2010].

A methanolic and a 20% methanolic extract at 100 µg/mL scavenged DPPH radicals (inhibition 93.6 and 89.8% respectively). These extracts, as well as a dichloromethane and a hexane extract, protected Vero cells against H_2O_2-induced oxidative stress ($p<0.001$) [Un 2015].

Pretreatment of HaCat human keratinocytes with two polar calendula extracts (not further specified) resulted in protection of H_2O_2-induced oxidative stress, which was most pronounced after 48 hours of pretreatment [Alnuqaydan 2015].

A methanolic extract (DER 5:1; 0.1, 0.2, 0.3 and 0.4 mg) dose-dependently protected rat brain mitochondria from oxidative damage induced by ascorbate as shown by reduced chemoluminescence and the composition of polyunsaturated fatty acids [Zeinsteger 2018].

A butanolic fraction of a 50% ethanolic extract inhibited the lipid peroxidation induced by Fe^{2+}/ascorbate in liver microsomes with an IC_{50} of 150 µg/mL [Cordova 2015].

Arnidiol-3-O-myristate from Calendula flower significantly reduced ROS generation induced by H_2O_2 at all the tested concentrations (0.01, 0.1 and 1 µg/mL), while ψ-taraxasterol-3-O-myristate resulted in a significant effect only at the lowest concentrations (0.01 µg/mL). In transepithelial resistance measurements neither compound altered the permeability of a Caco-2 cell layer. Under inflammatory stimulation with H_2O_2, or interferon-γ + TNF-α modulated oxidative stress and inflammatory conditions, a significant ($p<0.05$ to <0.0001) increase of the trans-epithelial resistance at 0.01 and 0.1 µg/mL was observed [Dall´Acqua 2015].

Rat brain microsomes incubated with a methanolic extract (DER 4.8:1) were protected against lipid peroxidation induced by Fe^{2+}/ascorbate [Palacios 2016].

Anti-inflammatory effects
A defatted, 70% ethanolic extract (DER 14:1) inhibited COX-2 with an IC_{50} value of 0.1 µg/mL, but remained without effect on 5-LOX [Chagas-Paula 2015].

In AGS cells, after stimulation with TNF-α, a significant inhibition of the NF-κB driven transcription by a CH_2Cl_2 extract was shown (5, 10 and 20 µg/mL; $p<0.05$, <0.001 and <0.001 respectively) [Colombo 2015].

Three isorhamnetin glycosides from calendula flower, at concentrations of 1.5×10^{-5} M, showed inhibitory effects on arachidonate 12-lipoxygenase from rat lung cytosol [Bezákova 1996].

Effects on buccal membranes
In a test system based on porcine buccal membranes, strong concentration-dependent adhesive processes were observed with a low-viscosity, polysaccharide-enriched extract (98% carbohydrates) of calendula flower [Schmidgall 2000].

Cytotoxic and anti-genotoxic effects
An ethyl acetate extract showed a proliferative effect on human skin fibroblast between 25 and 75 µg/mL; higher concentrations were cytotoxic. For a heptane and a methanol extract, proliferation was only seen at 25 µg/mL; all higher doses were cytotoxic. In human breast cancer cells T47D, the ethyl acetate extract resulted in proliferation at concentrations up to 175 µg/mL and the heptane extract up to 50 µg/mL. These two extracts at higher concentrations and the methanol extract from 25 µg/mL were cytotoxic [Matysik 2005].

An aqueous extract from Laser-irradiated Calendula flower suppressed proliferation of B9 murine fibrosarcoma cells with an IC_{50} of 60 µg/mL. In several other cancer cell lines the extract

at 250 µg/mL caused inhibition of between 72 and 100% by caspase-3 induction of apoptosis and accumulation in G_0/G_1 phase due to the downregulation of several cyclins and cyclin-dependent kinases [Jiménez-Medina 2006].

No cytotoxcicity was observed with a 50% ethanolic extract (yield 15.7%) for L929 and HepG2 cells up to 15 mg/mL [Fonseca 2010].

Human acute T leukaemia cells (J-45.01) were inhibited by a 70% methanolic dry extract with an IC_{50} of 330 µg/mL [Wegiera 2012].

An infusion (2 g drug in 100 mL water) was slightly cytotoxic for human melanoma Fem-x cells, HeLA cells and human chronic myelogenous leukaemia cells (IC_{50} 360µg/mL, 750 µg/mL and 870 µg/mL respectively). Lower cytotoxicity was observed against other cancer cell lines, but also against human peripheral blood mononuclear cells with and without stimulation by phytohaemagglutinin [Matíc 2013].

In human conjunctival WKD cells the LD_{50} of a CO_2 extract was 245 µg/mL [Arana 2015].

A hydromethanolic (80%) extract exhibited weak cytotoxic effects on HeLa and HepG2 cells with IC_{50} values of 256 and 330 µg/mL respectively [Miguel 2016].

In rat liver cell cultures, an aqueous and a hydroethanolic extract reversed unscheduled DNA synthesis induced by the carcinogen diethylnitrosamine at around 50 ng/mL and between 0.4 to 16 ng/mL, respectively. Evaluation of the genotoxicity of the extracts without diethylnitrosamine showed a genotoxic effect at concentrations from 25 to 100 µg/mL and from 3.7 to 100 µg/mL, which was three orders of magnitude above the protective dose [Pérez-Carreón 2002].

A butanol fraction and two triterpene saponin glycosides were cytotoxic for HepG2 cells (IC_{50} = 14.3, 7.35 and 3.73 µg/mL respectively) [Mohamed 2015].

In B16F1 melanoma cells, an ethyl acetate fraction from a 50% ethanolic extract (6.5-50 µg/mL) significantly ($p<0.05$) decreased melanin production induced by α-melanocyte-stimulating hormone in a dose-dependent manner. The fraction inhibited migration of the cells via a reduction of MMP-2 activity and expression, which was caused by the inhibition of the MAPK signaling pathway [Xuan 2019].

In a panel of 60 cancer cell lines, calenduloside F-6'-O-methylether was most potent against leukaemia (MOLT-4 and RPMI-8226), colon (HCC-2998), and melanoma (LOX IMVI, SK-MEL-5, and UACC-62) cells, with GI_{50} values of 0.77-0.99 µM. Calenduloside G-6'-O-methylether exhibited GI_{50} values of less than 20 µM against all of the cell lines, except for ovarian (IGROV1: GI_{50} 20.1 µM) and renal (UO-31: 33.3 µM) cancer cells [Ukiya 2006].

In the MTT assay three sesquiterpene glycosides from a dichloromethane extract showed cytotoxicity against human epithelial gastric cells AGS with IC_{50} values between 5.4 and 6.46 µM [D´Ambrosio 2015].

Other effects
An 80% ethanolic extract (DER 5:1) showed a spasmolytic effect on spontaneous contractions in rabbit jejunum (EC_{50} 0.78 mg/mL) and in acetylcholine- and histamine-induced contractions in guinea pig ileum (80-90% inhibition at 0.3 mg/mL), mediated by calcium channel blockade [Bashir 2006].

In vivo experiments

Effects on wound healing
Dried alcoholic and aqueous extracts of calendula flower in combination with allantoin, applied topically as a 5% ointment, stimulated epithelisation in surgically-inflicted standard wounds in rats [Klouchek-Popova 1981, Klouchek-Popova 1982].

Experimental incisions in rats were infected with *Staphylococcus epidermidis*. Topical treatment with a calendula cream (not further specified) resulted in accelerated cicatrisation compared to controls. The results were confirmed by histological examination [Perri de Calvalho 1991].

In a study in rabbits, the time taken for complete cicatrisation of experimental wounds was shortened by approximately 25% after topical treatment with hydrogel or powder preparations containing 10% of an ethanolic dry extract in comparison with vehicle-only controls [Oana 1995].

Enhanced healing of experimental wounds in buffalo calves was observed after topical treatment with an ointment containing 5% of a dry extract. Epithelisation accelerated and histopathological parameters improved in comparison with wounds treated with saline only [Ansari 1997].

In incision wounds of rabbits, topical treatment with a lotion containing 5% of a tincture (0.1 mL for 7 days) resulted in a significantly higher number of fibroblasts ($p<0.05$) as compared to controls and in a higher number of fibrocytes ($p<0.05$ as compared to baseline) in the wounds [de Oliveira Pagnano 2008].

A 70% ethanolic extract (yield 1.1%) was administered orally (20 and 100 mg/kg b.w.) or topically (dosage not given) to female Wistar rats with excision wounds for 10 days. The percentage of wound closure was significantly ($p<0.01$) greater in the verum groups (91.7%, 93.9% and 86.9% respectively) compared to the control group (51.1%) on day 8. Days for re-epithelisation were 17.7 for control and 16.1 for topical application, but significantly less after oral treatment (14 days with 20 mg/kg ($p<0.05$) and 13 days with 100 mg/kg ($p<0.01$)). On days 5 and 15 a significant increase ($p<0.05$ to $p<0.001$) was observed in the hydroxyproline and hexosamine content in the granuloma tissue after oral treatment with 100 mg/kg as compared with control [Preethi 2009c].

The same extract was tested in a burn wound model in rats at doses of 20, 100 and 200 g/kg b.w. orally for 10 days. The amounts of hydroxyproline and hexosamine significantly increased with the two higher doses at day 10 ($p<0.01$). The levels of acute phase proteins (haptoglobin, orosomucoid) were reduced significantly ($p<0.05$ to $p<0.001$ at 200 mg/kg). Antioxidant parameters (GSH, MDA, SOD, catalase) in the liver and markers of hepatic function (ALP, GOT, GPT) were also improved in the animals with burns [Chandran Preethi 2008].

After topical treatment of circular wounds in rats for 4, 7 and 14 days with an ethanolic dry extract (100 µL of a 1% solution in water), a better contraction of the wounds and of collagen formation on days 4 and 7 was observed. Significantly less epidermal hyperaemia ($p<0.026$) on day 7 and epithelial hyperplasia ($p<0.046$) on day 14 were seen [Parente 2009a].

An ethanolic extract, and two apolar fractions (hexane, dichloromethane) thereof, led to significant neovascularisation in the chorioallantoic membrane model ($p<0.05$). In rats with experimental wounds treated topically with 100 µL of a 1% aqueous solution of the extract, macroscopic evaluation demonstrated a faster cessation of serous exudation and thinner

and wetter crusts as compared to control. In the wounds of the verum group, less fibrin and hyperaemia and a higher collagen quantity were observed. Immunohistochemistry revealed an increase in the number of blood vessels as shown by VEGF staining [Parente 2012].

In New Zealand white rabbits, treatment of full-thickness dorsolumbar wounds (2 x 2 cm) with a 5% aqueous extract (not further specified; daily for 28 days) resulted in significantly better scores ($p<0.05$) for epithelialisation, inflammation, fibroblasts, neovascularisation and collagen fibre density, thickness and arrangement at days 21 and 28 as compared to saline [Mahdu 2013].

In Sprague Dawley rats with incision wounds, topical treatment with a gel containing 7% of a 70% ethanolic extract for 14 days resulted in significantly ($p<0.05$) higher collagen and hydroxyproline contents in the wounds or scars after 14, 21 and 45 days, as compared to control (no treatment) or gel base [Naeini 2012]. In a biomechanical investigation in the same experimental set-up, after 21 days, treatment with the 7% gel resulted in significantly ($p<0.05$) higher ultimate tensile strength of skin samples from the edges of the wounds as compared to control. In the histopathological study, treated tissues at 14 days showed complete re-epithelialisation and thicker epithelium, and more fibroblasts and neovascularisation were seen than in the control and placebo groups. After 21 days, treated tissues were more organised with thinner epithelium and very few inflammatory cells in the lesion in comparison to control and placebo. The number of fibroblasts was reduced due to their change to mature organized fibrocytes, which were aligned along the reparative connective tissue [Shafeie 2015].

Wistar rats with partial transection of the Achilles tendon were treated with a cream containing 4% of a glycolic extract (1:1) on the wound before suture and for 5 further days topically. In the transected region the hydroxyproline concentration (as a marker for collagen concentration) and the amount of non-collagenous proteins were significantly ($p<0.05$) increased as compared to the operated control group. Other parameters characteristic for remodeling (amount of the isoforms of metalloproteinase-2 and -9 (MMPs), birefringence of tendon sections, chondroitin-6-sulfate) were not or only slightly improved with the cream [Aro 2015].

Topical treatment of excisional wounds in BALB/c mice for 6 days with 150 mg/kg of either a 50% ethanolic extract (yield 32%) or a water fraction thereof, significantly enhanced wound closure ($p<0.05$ at day 7) with complete closure at day 13 [Dinda 2016].

Photoprotective effects
The depletion of GSH in the skin of hairless HRS/J mice due to irradiation with UV-B was restored to non-irradiated control levels after oral treatment with a 50% ethanolic extract (yield 15.7%) at doses of 150 or 300 mg/kg b.w. 30 minutes and 18 hours prior to radiation ($p<0.05$). MMP-2 and MMP-9 were elicited by the extract [Fonseca 2010]. In a similar experiment, the animals received the extract at a concentration of 5% in a topical formulation 1 hour before, immediately before and 1 hour after irradiation. The treatment restored GSH levels to non-irradiated control levels ($p<0.05$). Modifications of collagen fibrils in the skin induced by irradiation were reduced [Fonseca 2011].

In Wistar rats treated topically with formulations containing 3 and 4% (w/v) of the essential oil, the photoprotection was not superior to the effect of the same formulation containing sunflower oil instead of calendula essential oil [Mishra 2012a].

Topical treatment of Wistar rats prior to UV-B radiation with creams containing 4 or 5 % of the essential oil resulted in significantly increased SOD, catalase, GSH, total protein and ascorbic acid levels ($p<0.05$ for all parameters and both dosages) in the skin as compared to irradiated controls. The elevated MDA content after irradition was significantly ($p<0.05$) reduced [Mishra 2012b].

Anti-inflammatory effects
A lyophilized extract, administered i.p., suppressed inflammatory effects and leukocyte infiltration induced by simultaneous injection of carrageenan and prostaglandin E1 into rats [Shipochliev 1981].

A dry 80% ethanolic extract, given orally 1 hour before oedema elicitation, inhibited carrageenan-induced rat paw oedema by 11% at a dose of 100 mg/kg body weight. In the same experiment indometacin at 5 mg/kg resulted in 45% inhibition of oedema [Mascolo 1987].

An aqueous dry extract (not further specified), at single doses of 50, 150 and 450 mg/kg b.w., was administered orally to Wistar rats. In paw oedema induced by carragenan and histamine, and in ear oedema induced by croton oil, the two higher doses exhibited significant inhibition ($p<0.05$). In serotonin-induced paw oedema all doses showed significant effects ($p<0.05$), but after challenge with dextran only the highest dose was significant ($p<0.05$). In cheek pouch granuloma the animals were treated with the extract for 7 days, and at 150 and 450 mg/kg significant ($p<0.05$) improvement was observed [Núnez-Figueredo 2007].

Oral pretreatment of BALB/C mice with a 70% ethanolic extract (yield 1.1%; 250 and 500 mg/kg b.w.) resulted in a significant ($p<0.001$) inhibition of dextran-induced (41.9 and 42.4% respectively) and carrageenan-induced (50.6 and 65.9% respectively) paw oedema. In the model of chronic inflammation with formalin-induced oedema the reduction was 32.9 and 62.3% respectively. The pronounced increase of inflammatory cytokines (IL-1β, IL-6, TNF-α, INF-γ and CRP) in serum after stimulation with LPS decreased significantly after pretreatment with 50, 100 or 250 mg/kg of the extract ($p<0.001$ for all doses and cytokines). COX-2 expression in the spleen was inhibited by 250 mg/kg of the extract [Preethi 2009a].

The effects of topical application of gels containing 5 or 10% of an 80% ethanolic extract on 5-fluorouracil-induced mucositis were studied in Syrian hamsters from day 12 (maximum severity of mucositis) until day 17. Weight gain of the animals was significantly higher from day 13 until the end of the study with both treatments ($p<0.04$ to $p<0.001$) as compared to control and animals treated with gel base. Microscopic and macroscopic scores of mucositis were lower in the 5% and 10% gel groups as compared to the gel base and control groups ($p<0.05$) [Tanideh 2013].

Oral treatment of male Sprague–Dawley rats with 0.5g/kg daily of a dry ethanolic extract (not further specified) for 6 weeks significantly ($p<0.05$) reduced aflatoxin-induced increases of TNF-α and IL-1β [Abdel-Aziem 2014].

The anti-inflammatory effect of a 70% ethanolic extract was studied in formalin-induced inflammation of the rat paw. A significant ($p\leq0.001$) decrease in paw thickness was observed after oral administration of 250 mg/kg [Elzorba 2016].

An ethanolic extract (8.7% yield; 400 mg/kg b.w. orally/day for 14 days) attenuated several pathological parameters of pancreatitis induced by L-arginine in Sprague-Dawley rats: the enhanced serum lipase and drastically reduced pancreatic

amylase, as well as changes in pancreatic DNA, RNA and total protein content, were significantly ameliorated ($p<0.05$). The extract protected against damage to the pancreatic architecture by markedly decreasing inflammatory cells and oedema. Markers of oxidative stress and indicators of regeneration were impoved [Kaur 2016].

A calendula extract administered orally and by enema exhibited dose-dependent beneficial activity in Sprague-Dawley rats with acetic acid-induced ulcerative colitis. Treatment for 7 days with an 80% ethanolic dry extract (18.2% yield) at doses of 1.5 or 3 g/kg b.w. p.o., or as an enema containing 10 or 20% of the extract, resulted in significantly ($p<0.05$) higher weight gain in each of the calendula treated groups, as compared to negative control (oral saline or base gel). Most of the histopathological changes of the colonic tissue, such as acute inflammation and granular atrophy, were significantly ($p<0.05$) improved in the 20% intracolonic gel and both oral calendula groups, as compared to the negative controls, with the higher oral dose exhibiting almost complete reversal. The inflammatory markers, MDA and myeloperoxidase (MPO) activity, were also significantly ($p<0.05$) lower in the treated groups than negative controls [Tanideh 2016].

In a similar study, male Wistar rats were treated orally with 100 or 200 mg/kg b.w. of a 70% ethanolic dry extract (yield 18.7%) for 7 days before intracolonic challenge with acetic acid for the induction of ulcerative colitis. Clinical and macroscopic scores including weight loss, stool consistency, bleeding etc. were significantly ($p<0.001$) less in the pretreated groups as compared to acetic acid control. Increased concentrations of MPO, colonic lipoxyperoxidase and LDH, as well as the decreased GSH level in colonic tissue, were improved significantly ($p<0.001$) by the lower dose of the extract, with a less pronounced effect shown by the higher dose [Banakar 2016].

In an experimental model of periodontitis in male Wistar rats, the alveolar bone loss by ligature of the second upper left molar was improved by an aqueous extract (not further specified; 90 mg/kg/day by gavage for eleven days). Changes in bone topography and dearrangement of collagen fibers in the periodontal ligament were impeded. Reduced gingival GSH, SOD and CAT levels, increased gingival MDA and the changes in the count of immunopositive cells for WNT 10b, β-catenin and DKK-1 were significantly (all $p<0.05$) reversed by the treatment [Lima 2017].

In a similar study with the same extract (10, 30 and 90 mg/kg/day for eleven days), the highest extract dose significantly ($p<0.05$) prevented alveolar bone loss and the reduction of bone-specific alkaline phosphatase in serum and of osteoprotegerin immuno-expression. Leukocyte infiltration, increased myeloperoxidase activity and gingival concentrations of TNF-α, IL-1b and RANKL due to ligature were decreased at the highest dose ($p<0.05$). The extract did not affect kidney and liver functions as shown by serum AST/ALT levels [Alexandre 2018].

A 70% alcoholic extract and a supercritical CO_2 extract were applied topically in the croton oil ear oedema test in mice. The hydroalcoholic extract had a mild dose-dependent effect, inhibiting oedema by 20% at a dose of 1200 µg/ear, corresponding to 4.16 mg of crude drug. The CO_2 extract produced 30% inhibition at 150 µg/ear, corresponding to 3.6 mg of the crude drug, and 71% inhibition at 1200 µg/ear, corresponding to 28.6 mg of crude drug. The activity at the higher concentration was comparable to that of indometacin at 120 µg/ear [Della Loggia 1990]. In the same model, triterpenoids were shown to be the most important anti-inflammatory principles in the CO_2 extract [Della Loggia 1994].

In the same test system in male albino Swiss mice, a faradiol monoester mixture, faradiol-3-myristic acid ester, faradiol 3-palmitic acid ester and ψ-taraxasterol isolated from calendula flower all showed significant ($p<0.05$) anti-oedematous activity compared to controls at doses of 240 and 480 µg/cm^2. Faradiol (which is not present in the free form in calendula flower) proved to be even more active than the esters with an anti-oedematous effect comparable to that of an equimolar dose of indometacin, but 3-esterification reduces the activity by more than 50% [Della Loggia 1994, Zitterl-Eglseer 1997].

Helianol and ψ-taraxasterol from calendula flower inhibited inflammation induced by 12-O-tetradecanoylphorbol-13-acetate (1 µg per ear topically) in female ICR mice. The 50% inhibitory doses were 0.1 mg/ear for helianol and 0.4 mg/ear for ψ-taraxasterol, compared to 0.3 mg/ear for indometacin [Akihisa 1996]. Several other triterpenes from calendula flower showed ID_{50} values of 0.03 to 0.2 mg/ear in the same animal model [Yasukawa 1996].

A pronounced anti-inflammatory activity was shown for several oleanane-type triterpene glycosides in TPA-induced mouse ear inflammation with ID_{50} values between 60 and 200 µg/ear [Ukiya 2006].

Topical application of faradiol in mouse ear oedema induced by croton oil resulted in an ED_{50} of 0.13 µmol/cm^2 of ear [Neukirch 2005].

Angiogenic effects
The angiogenic activity of a lyophilized aqueous infusion (1:10) was tested in the chick chorioallantoic membrane (CAM) test. The numbers of micro-vessels in tissue sections of treated CAMs were significantly higher ($p<0.0001$) than in control CAMs. All treated CAMs were positive for hyaluronan, while no hyaluronan was detected in control CAMs [Patrick 1996].

Antitumour effects
In ANDO-2 human melanoma implanted nude mice, treatment with an aqueous extract (laser-irradiated at 650 nm during extraction) at 50 mg/kg/day p.o. three times a week for 12 weeks, or 25 mg/kg i.p. twice a week for 9 weeks, resulted in similar inhibitions of tumour growth of 60%, which was also similar to taxol as positive control. The survival rate at the end of the study was 0% for saline control, 40% for taxol, 75% for the extract i.p and 60% for the extract p.o. [Jiménez-Medina 2006].

In male C57BL/6 mice injected with B16F-10 melanoma cells and simultaneously treated with an ethanolic dry extract (yield 1.1%; 250 mg/kg p.o. daily for 10 days), the number of lung tumour nodules was decreased significantly ($p<0.001$) and the life span of tumour bearing mice increased by 43.3%. The extract caused a pronounced reduction of the elevated levels of lung hydroxyproline, uronic acid, hexosamine, serum sialic acid and γ-glutamyl transpeptidase as compared to metastatic controls; the drastic increase in the level of proinflammatory cytokines (IL-1β, IL-6, TNF-α, GM-CSF) and the growth factor (VEGF) in metastasis-bearing animals was significantly ($p<0.001$) inhibited by the extract. The expression of genes involved in metastasis, including MMPs, prolyl hydroxylase and lysyl oxidase, was inhibited, while tissue inhibitors of MMPs were activated [Preethi 2010].

In male Sprague-Dawley rats, aflatoxin-induced micronucleus formation in bone marrow cells, changes in the gene expression of p53, Bax and Bcl-2 as well as in the hepatic tumour marker AFP, were significantly ($p<0.05$) improved by oral treatment with 0.5 g/kg daily of a dry ethanolic extract (not further specified) for 6 weeks. DNA fragmentation in the liver was not fully restored [Abdel-Aziem 2014].

A methanolic extract was tested in a model for experimental skin carcinogenesis in female Swiss albino mice for 32 weeks. The animals were challenged with 7,12-dimethylbenz(a) anthracene and treated twice weekly with croton oil as a tumour promoter for 16 weeks. The extract (100 µL; 10 mg/kg) was applied topically 1 hour before croton oil, and alone twice a week for a further 16 weeks. The tumour incidence was reduced by the extract; the decrease of tumours per mouse was significant ($p<0.05$). Histological changes in the skin due to the carcinogens were improved. The proliferative population in tumours was diminished by restoration of the endogenous antioxidant defense, the inhibition of NFκB, the reduction of inflammation, the enhancement of immunosurveillance of the genetically mutated cells, along with silencing of the cell cycle progression signals. The extract induced stable expression of p53 tumour suppressor protein within the tumours [Ali 2014].

Wistar rats challenged with *N*-diethylnitrosamine, followed by three doses of 2-acetylaminofluorene (2-AAF) as promotor on days 7, 8 and 9 after challenge, and partial hepatectomy on day 10, were treated orally with various doses of an enriched hydroethanolic extract (0.45% yield; ethanol concentration 0.8%) for 18 days. Histological inspection of the development of altered hepatocyte foci (AHF) revealed a protective effect of the extract as shown by the area and number of AHF starting at 0.1 mg/kg, increasing at 0.5 and reaching a maximum at 2.5 mg/kg b.w. At higher doses (10, 20 and 40 mg/kg) an increase of AHF area and numbers above the level of the control were observed. Substitution of the promotor 2-AAF by 40 mg/kg of the extract also resulted in significant promotion ($p<0.01$ for area and <0.006 for numbers) [Barajas-Farias 2006].

A triterpene-enriched fraction given orally to mice inoculated with Ehrlich mouse carcinoma prevented the development of ascites and increased survival time compared to controls [Boucaud-Maitre 1988].

Hepatoprotective effects

Administration of a fluid extract (1:1; 10 mL/kg b.w. p.o.) to male Wistar rats with CCl_4-induced hepatotoxicity resulted in a marked improvement of the increased SGPT activity but did not show an effect on the increased SGOT activity. CCl_4-induced histological changes were reduced. Modifications in the activity of several enzymes and in steatosis were ameliorated [Rusu 2005].

Oral pretreatment with an ethanolic extract (yield 1.1%; 100 and 250 mg/kg b.w. daily for 3 days) protected female Wistar rats against CCl_4-induced hepatotoxicity. The CCl_4-induced increases in serum marker enzymes of liver injury (SGOT, SGPT and ALP), total bilirubin, and MDA as a marker of lipidperoxidation in liver tissue, were significantly ($p<0.05$ to $p<0.001$) reduced by both doses of the extract [Preethi 2009b].

Antioxidant effects

Oral administration of an ethanolic extract (100 and 250 mg/mL) to female Swiss albino mice led to an inhibition (12.6 and 38.7% respectively) of superoxide radical generation during the activation of sodium caseinate-induced macrophages with phorbol-12-myristate-13-acetate. In a second experiment, mice were treated with three different doses (50, 100 and 250 mg/kg b.w.) for 30 days. Changes of the antioxidant status in the blood included an increase in catalase, significant for 50 and 100 mg/kg ($p<0.005$), a decrease in superoxide dismutase ($p<0.001$ for 50 mg/kg) and of glutathione peroxidase ($p<0.001$ for 250 mg/kg). Glutathione was significantly enhanced in all treated groups ($p<0.005$, $p<0.001$). Changes in glutathione reductase were not significant [Preethi 2006].

In male pigs, DNA damage was induced by oxidative stress due to a high intake of polyunsaturated fatty acids (30% energy from linseed oil). Oral treatment with 3 mL/day of an aqueous propylene glycol extract from fresh flowers for 14 days resulted in a significant ($p<0.05$) reduction of DNA damage in peripheral blood lymphocytes. The amount of 8-hydroxy-2′-deoxyguanosine, a biomarker of generalized oxidative DNA damage, in urine decrased [Frankič 2009].

Sprague-Dawley rats exposed to cigarette smoke daily received a dry ethanolic extract (100 mg/mL/day) or placebo orally for 23 days. Body weight increased in unexposed controls, decreased in animals exposed to smoke and remained unchanged in the extract group. Serum markers of renal function remained unchanged; the HDL-reduction and increased serum AST, LDH and creatine after smoke exposure were significantly ($p<0.05$) improved by the extract [Ozkol 2011].

The influence of an extract (appr. 35% ethanol; 100 mg/kg b.w./day p.o.) on alterations in the oxidant status generated by exposure to cigarette smoke was investigated in Sprague-Dawley rats. Parameters of the cellular antioxidant defense system such as SOD, glutathione peroxidase, glutathione reductase and GSH were investigated in lung, brain and heart. All changes due to cigarette smoke were improved by the extract [Özkol 2012].

In male Sprague–Dawley rats receiving 0.5 g/kg daily of a dry ethanolic extract (not further specified) orally for 6 weeks, the levels of the inflammatory cytokines TNF-α and IL-1β remained unchanged. Markers of oxidative stress (MDA in the liver, hepatic glutathione peroxidase, SOD) were improved as compared to untreated controls [Abdel-Aziem 2014].

The effects of a dry ethanolic and a dry aqueous extract (not further specified, 300 mg/kg b.w. p.o. 1 hour before and 24 and 48 hours after challenge with cisplatin) on cisplatin-induced nephrotoxicity in Wistar rats were studied. The extracts significantly ($p<0.05$) reduced the elevated blood creatinine levels after cisplatin. Both treatments improved the cisplatin-detoriated plasma total antioxidant status (TAS), total thiols and oxidative stress index ($p<0.05$), the ethanolic extract also improved the total oxidant status, GSH, CAT and GST ($p<0.05$). In renal tissue both extracts restored TAS and MDA levels ($p<0.05$), and the ethanolic extract restored Cat, GPx and GST activities. Histopathological findings showed less severe degenerative and necrotic changes in renal tubular epithelium after co-treatment with both extracts [Verma 2016].

Other effects

A methanolic extract (yield 35.3%) and its 1-butanol-soluble fraction were tested for their effects on serum glucose after glucose-load and on gastric emptying in mice, as well as for gastroprotective effects in rats. A significant reduction of the glucose level after challenge was only seen for the butanolic fraction (500 mg/kg p.o.; $p<0.01$). The extract (500, 1000 mg/kg) and the fraction (250, 500 mg/kg) inhibited gastric emptying in carboxymethyl cellulose sodium salt meal-loaded mice after oral application ($p<0.01$). Gastric lesions in rats after ethanol or indometacin challenges were significantly ($p<0.01$) improved by the extract (100 and 200 mg/kg) and the fraction (50 and 100 mg/kg). Some of the oleanane-type triterpene oligoglycosides showed effects as well [Yoshikawa 2001].

Oral administration of a 50% hydroethanolic extract to male Wistar rats (200 mg/kg daily for 60 days) significantly decreased the weight of the testis, epididymis, seminal vesicle and ventral prostate ($p<0.001$). Sperm motility and sperm density were reduced ($p<0.001$), resulting in 80% loss of fertility. Serum testosterone as well as total protein and sialic acid in the testis, epididymis, seminal vesicles and ventral prostate showed

significant reduction ($p<0.001$); testicular cholesterol was elevated. All measured haematological parameters remained unchanged [Kushwaha 2007].

Treatment of Swiss albino mice with an ethanolic extract (yield 1.1%; 100 and 250 mg/kg b.w.daily p.o.) for 3 days prior to and 3 days after challenge with cisplatin diminished kidney damage as shown by a significant ($p<0.001$) reduction of increased urea and creatinine at both doses. Increased lipid peroxidation was not influenced by the extract. SOD activity and glutathione content, which remained unchanged by cisplatin, were significantly elevated with the 250 mg extract ($p<0.05$ and 0.01 respectively). The decrease of catalase was abolished by both doses of the extract ($p<0.01$ and 0.001). Diminished white blood cell count was improved at the higher dose ($p<0.01$) [Preethi 2009b].

In male Swiss albino mice receiving a dry ethanolic extract (0.1, 0.3 and 1 g/kg b.w. p.o.), a dose-dependent elongation of pentobarbital-induced sleeping time, significant ($p<0.05$) at the highest dose, was determined. In the Rotarod performance test, the extract at 0.5, 1 and 2 g/kg p.o. slightly decreased endurance and increased the number of falls to a similar extent at all doses. In the open field test, entrances in the open square were diminished and time of immobilisation raised, both significant ($p<0.05$) at the two higher doses [Parente 2009b].

An 80% ethanolic extract was administered to male Wistar rats at doses of 100, 150 or 250 mg/kg b.w. (i.p.). In the tail flick test, a significant elongation of tail flick latency was observed ($p<0.05$, 0.01 and 0.05 respectively). The number of writhings induced by acetic acid was significantly reduced ($p<0.01$, 0.001 and 0.001 respectively) [Shahidi 2012].

The neuroprotective activity of a 70% methanolic extract (18.7% yield) against 3-nitropropionic acid-induced damage was studied in Wistar rats. Oral treatment with the extract at 100 or 200 mg/kg/day for 14 days significantly improved the decrease in body weight ($p<0.001$ and 0.05 respectively). Most of the changes in motor- and cognition-related behaviours as studied in various models and in the antioxidant status in the rat brain such as catalase, MDA etc. were ameliorated significantly ($p<0.05$ to $p<0.001$) and more pronounced with the lower dosage [Shivasharan 2013a].

In a similar study with the same extract (100 or 200 mg/kg p.o. for 7 days), neurotoxic effects in Wistar rats were induced by sodium glutamate. Decreased locomotor activity was enhanced by the extract ($p<0.01$ at the higher dose). The negative influence of sodium glutamate on oxidative stress parameters in the brain such as GSH, total thiols, glutathione-S-transferase, catalase, MDA and nitrite was improved [Shivasharan 2013b].

Dogs infected with sarcoptic mange were treated with the antiparasitic compound ivermectin (0.2 mg s.c.) alone, in combination with 50 mg p.o. of an 80% ethanolic extract per day (CFE), or combined with an oral dose of 70 mg *N*-acetylcysteine twice daily as a positive control (NAC). Parasitical cure rates were 25%, 75% and 87.5%, respectively, after 14 days of treatment and 75%, 100% and 100% after 28 days.The improvement of the *Sarcoptes*-induced skin lesions score was significant after 14 and 28 days in the CFE and NAC groups as compared to baseline, but only after 28 days in the ivermectin alone group ($p<0.01$). CFE and NAC at both time points were superior to ivermectin alone ($p<0.01$) with no significant differences between CFE and NAC. All tested markers of oxidative stress in peripheral blood (lipid peroxides, reduced glutathione, glutathione peroxidase, glutathione-S-transferase, SOD and catalase) that had been significantly influenced by the infection ($p<0.001$) were ameliorated similarly and significantly in the CFE and NAC groups ($p<0.001$) compared to baseline [Singh 2013].

Streptozocin-induced diabetic male Wistar rats received a dry, 80% ethanolic extract (300 mg/kg b.w. by gavage) for 13 weeks. Levels of serum glucose, urea, creatinine and malondialdehyde and the total oxidant status increased, the total anti-oxidant capacity decreased and damage in the glomerulus and mass infiltration in kidney tissue was observed in diabetic rats as compared to non-diabetic controls. The extract had no effect on blood glucose, but did decrease blood urea nitrogen, creatinine, the total oxidant status and malondialdehyde and increase total anti-oxidant capacity. It did not prevent histological signs of nephropathy in the diabetic rats [Salehi 2015].

In brewer´s yeast-induced hyperthermia in rats, a 70% ethanolic extract (250 mg/kg p.o.) led to a significant ($p\leq0.05$) reduction of the elevated temperature after 3 hours, comparable to metamizol sodium (50 mg/kg) as the positive control. Administration of the extract to mice (250 mg/kg p.o.) in the writhing test showed a 20% inhibition of acetic acid-induced writhing for 5 hours [Elzorba 2016].

Treatment with saponins from calendula flower changed the glycosylation pattern in infective larvae of *Heligmosomoides polygyrus*, an intestinal parasitic nematode, which resulted in a significantly ($p<0.001$) reduced level of infection in BALB/c mice infected with third stage larvae. In these mice the production of TNF-α in the intestine and in serum increased significantly ($p<0.05$) [Doligalska 2013].

Oleanolic acid and three fractions from calendula flower containing oleanolic acid 3-O-glucoside, other glucosides of oleanolic acid and oleanolic acid glucuronides, respectively, significantly ($p<0.001$) inhibited the development of L3 larvae of *Heligmosomoides polygyrus*. The concentration of a mixture of all oleanolic acid glycosides, at which 50% of hatched larvae failed to develop fully into infective stage L3 larvae, was 350 µg/mL of oleanolic glucuronides [Szakiel 2008].

Pharmacological studies in humans

The effects of various preparations on sodium lauryl sulfate-induced irritant contact dermatitis were tested in 20 healthy volunteers. A dyed and an undyed extract, a faradiol ester-enriched fraction, faradiol myristic acid ester and faradiol palmitic acid ester (as 5% in a cream) were applied topically 10 min after irritation on four days. All preparations resulted in significant ($p<0.05$ to $p<0.001$) improvement as evaluated by visual inspection, measurement of transepidermal water loss and of erythema as compared to untreated controls [Fuchs 2005].

In four healthy males, topical application of a 50% solution of the essential oil of calendula flower in absolute ethanol showed weak repellency against *Anopheles stephensi* with a mean protection time of 2.15 hours and an ED_{50} of 0.6034 mg/cm^2 [Tavassoli 2011].

Clinical studies

Wound healing

In a randomized, open, controlled study, the effects of three ointments were compared after topical treatment of patients with 2nd or 3rd degree burns for 17 days: a calendula flower ointment (prepared by digestion in vaseline, no further information; n = 53) or vaseline only (n = 50) or a proteolytic ointment (n = 53). The success rates were considered to be 37/53 for the calendula ointment, 27/50 for vaseline and 35/53 for the proteolytic ointment. Calendula flower ointment was marginally superior to its base, vaseline ($p = 0.05$) [Lievre 1992].

In an open, uncontrolled pilot study, 30 patients with burns or scalds (degrees 1 and 2a) were treated 3 times per day for up to 14 days with a hydrogel containing 10% of a hydroethanolic extract. The symptoms reddening, swelling, blistering, pain, soreness and heat sensitivity were scored before, during and at the end of treatment. The total score and individual scores for each symptom improved [Baranov 1999].

Patients with lower leg venous ulcers received treatment for 3 weeks with either local application of 1g/cm^2 of an ointment (7.5% of an ethanolic extract (DER 15.6:1) in propylene glycol) twice daily (n=21) or saline solution dressings as control (n=13). The reduction of the total surface of all ulcers in the verum group was 14.6%, 33.3% and 41.7% after the first, second and third week respectively. In 7 patients complete epithelialisation was observed. In the control group the reductions were 4.1%, 10% and 14.5% and complete epithelialisation occurred in four patients [Duran 2005].

After surgical removal of small pigment neoformations, 28 patients were randomly assigned to one of two groups to determine wound healing and inflammation. Wounds were treated either with iodine solution on days 0, 3, 7 and 10 (A), or on day 0 with iodine and on days 3, 7 and 10 with a hydroethanolic extract (B). Wound areas decreased from day 3 to day 15 from 0.55 to 0.30 cm^2 (42.1%) in group A and from 0.80 to 0.45 cm^2 (44.7%) in group B. Inflammation, as determined by differences in the colour of the affected area and the adjacent unaffected area, was reduced from 22.5 to 14.9 (group A) and from 31.3 to 29.9 (group B) [Raposio 2007].

In a randomized, double-blind, comparative study, the effects of an ointment containing 1.5% of an extract (not further specified; n=34) were compared to an aloe cream (containing aloe vera gel and olive oil in a base cream; n=32) in diaper dermatitis in infants (up to 3 years of age). The creams were applied 3 times a day for 10 days. Severity was determined by a 5-point scale at the beginning and on days 5 and 10 of treatment, and decreased significantly ($p<0.001$) in both groups as compared to baseline. The reduction of symptoms was significantly ($p<0.001$) higher in the group receiving the calendula ointment [Panahi 2012].

In a randomized, controlled, blinded study, primiparous women with episiotomy were treated on the episiotomy area with either 3 cm^3 calendula ointment (not further specified) every 8 hours (n=37) or with a povidone iodine solution every four hours (n=37) as control, both for five days. Healing was evaluated with the REEDA (redness, oedema, ecchymosis, drainage, approximation) scale. After 5 days a significantly ($p<0.001$) better healing was seen with the calendula ointment in the REEDA scale as compared to control [Eghdampour 2013].

During surgical extraction of a third molar, patients (n=44) received irrigation with either a dilution of a mother tincture (10% in physiological solution) or with physiological solution alone. The same agents were used for 1 week as a mouthwash after brushing the teeth. The verum resulted in significantly ($p<0.05$) better bone preservation after extraction. Patients in the verum group experienced less pain during the first 24 hours after extraction and after one week, less bleeding and needed less antibiotics [Uribe-Fentanes 2018].

Effects on radiation-induced skin damage

In a randomized, single-blind trial, 254 patients undergoing postoperative radiation therapy, following breast cancer surgery, applied either trolamine (n=128; A) or an ointment containing a lipophilic extract of calendula flower (n=126; B) to the irradiated field after each session. The occurrence of acute dermatitis of grade 2 or higher was significantly lower (41% vs. 63%; $p<0.001$) with the use of calendula compared to trolamine. The mean maximal pain evaluated on a VAS was 2.10 in group A and 1.54 in group B ($p=0.03$). Patients in group B had less frequently interrupted radiotherapy [Pommier 2004].

To reduce acute radiation skin reactions (ARSR), 411 patients with adjuvant radiotherapy (RT) for breast cancer applied a thin layer of a calendula cream (10% of a non-specified extract) or an aqueous moisturizing cream twice daily from the onset of RT until two weeks after the end of RT. In this randomized, blinded study, ARSR were evaluated by the RTOG/EORTC scale at the first and the final radiation and 5 to 17 days after the final radiation. Patients recorded pain, burning, itching, pulling and tenderness on a VAS and completed the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core-30 and the MoS sleep questionnaire. No differences in ARSR were observed between the groups [Sharp 2013].

The effect of a gel containing 2% of an extract (70% ethanol) on radiation-induced oropharyngeal mucositis was studied in a randomized, double-blind, placebo-controlled study in 40 patients with head-and-neck cancers undergoing radiotherapy. The patients applied 5 mL of the gel twice daily for at least one minute for 7 weeks from the outset of radiation. Oropharyngeal mucositis was evaluated by the oral mucositis assessment scale (OMAS). The verum significantly decreased the intensity of oropharyngeal mucositis compared to placebo at week 2 (score: 5.5 vs. 6.8, $p = 0.019$), week 3 (score: 8.25 vs. 10.95, $p < 0.0001$) and week 6 (score: 11.4 vs. 13.35, $p = 0.031$) [Babaee 2013].

In a randomized, double-blind, controlled study 51 patients with head and neck cancers undergoing radiotherapy were treated twice daily with a calendula preparation (4% calendula oil (not further specified) and 1% vitamin A in liquid petroleum jelly) or a fatty acid preparation (EFA; 5% capric acid, 1% vitamin A and 0.2% vitamin E in sunflower oil) on the complete treatment field. Radiodermatitis was evaluated every 5th radiation and developed from the 10th session with severity of grades 1 to 3 according to RTOG. In the calendula group the proportion of radiodermatitis grade 2 was significantly lower ($p=0.012$), and the survival curve remained significantly higher ($p=0.00402$), as compared to EFA [Schneider 2015].

Effects on gingivitis and periodontitis

Forty patients with established gingivitis brushed their teeth with standard toothpaste (control), or standard toothpaste with 2% of a dry ethanolic extract, three times daily for two minutes according to the Bass method in a 4 week randomized, double-blind, controlled study. Plaque index (PI), gingivitis index (GI) and bleeding on probing (BoP) were analysed at baseline and at the end of weeks 2, 3 and 4. The PI was reduced significantly after 4 weeks as compared to baseline and to control ($p<0.0001$; reduction 33.4% vs. 9.8% after 4 weeks). A significant difference between control and verum was observed after 2, 3 and 4 weeks in GI ($p<0.004$, 0.0001 and 0.0001 respectively), with a decrease of 46.3% after verum and 18.4% after control at the end of the study. A similar progress was seen in BoP ($p<0.001$, 0.0001 and 0.0001 respectively), with a decrease of 50.8% after verum and 21.8% after control after 4 weeks [Amoian 2010].

In a controlled study, 40 patients with chronic periodontitis applied a mouthwash containing a standardized tincture (not further specified) or a 0.12% chlorhexidine solution, three times per week for two weeks. Clinical attachment level, marginal bleeding, Plaque Index of O'Leary and Gingival Index were determined. The effects of both rinses were similar in most parameters, the difference was significant only on the Gingival

Index, with chlorhexidine being superior to the tincture (p = 0.02) [Vinagre 2011].

In a randomized, controlled study, 240 patients exhibiting gingivitis, with bleeding on probing and a probing depth ≤3 mm, used a mouthwash of either a mother tincture (not further specified; 2 mL diluted with 6 mL water) or 8 ml distilled water (control) twice daily for six months. All patients received a thorough scaling procedure at a 3 month visit. Plaque index, gingival index, sulcus bleeding index and oral hygiene index–simplified were all significantly (p<0.01) improved after six months in the verum group; while after three months (prior to the scaling procedure) only the latter index had not significantly improved. In the control group no significant changes in the four parameters were observed after three months. The improvement after six months was less pronounced than after verum [Khainar 2013].

Effects on diabetic ulcers
In a prospective study, 41 patients with an average glycaemic level of 153 mg/dL, and diabetic foot ulcers (DFU; size 0.5–40 cm^2) of more than 3 months duration, were treated twice daily with a spray solution containing 4% of a hydroglycolic extract (6.7% amyrin, 4.7% lupeol, 8.1% ψ-taraxasterol, 5.5% calenduladiol monoesters, 15.7% arnidiol monoesters, 35.2% faradiol monoesters and 120mg/mL total flavonoids). Size, microbial flora, odour and tissue type of DFU, exudate, retraction rate and pain on a 10-point rating scale were evaluated every second week for 30 weeks or until healing. Blood parameters and neuropathic pain were assessed at baseline and at the end of treatment. Complete wound closure after 11, 20 and 30 weeks was observed in 54%, 68% and 78% of the cases. After 30 weeks, the number of colonized wounds decreased from 29 at baseline to 5, and the number of odorous wounds decreased from 19 to 1. A significant (p=0.001) reduction in the amount of exudate, fibrin slough and necrotic tissue was observed [Buzzi 2016a].

In a randomized, controlled study, 32 type-II diabetic patients with lower limb ulcers received either no treatment, low-level laser therapy, calendula oil (5 mL/day; not further specified) or a combination of low-level laser therapy with calendula oil for 30 days. The oil did not influence the diameter of the posterior tibial artery and the Ankle-Brachial Index (parameters of peripheral circulation). In the Brief Pain Inventory Questionnaire and a VAS to quantify pain the oil produced no effect, although the total ulcer area was reduced [Carvalho 2016].

Effects in vaginal candidiasis
In an open study, 42 patients with recurrent vaginal candidiasis were treated topically with 8.6 mL of a solution prepared from 15 mL of a tincture (200 g drug in 1 L ethanol 70%) in 200 mL water, three times per week for 2 weeks. Evaluations on day 0, day 21 and day 30 included grade and persistence of leucorrhea, persistence of pruritus, a gynaecological examination and a check of vaginal exudate for *Candida* sp. All parameters were improved significantly on day 30 as compared to baseline (p=0.000, each) [Milián Vázquez 2010].

In a triple-blind, randomized study, patients with vaginal candidiasis (n=150) applied 5 g of either a cream containing 1% of an ethanolic dry extract (DER 5:1) or of a 1% clotrimazole cream every night for 7 nights. In the follow-up between day 10 and 15, significantly (p<0.001) more women in the clotrimazole group had a negative mycological test for Candidiasis as compared to the calendula group (55 vs. 34%). In contrast, the outcome in the assessment after 30 and 35 days was reversed with 54% without Candidiasis in the calendula group and 25% in the clotrimazole group (p<0.001). In individual complaints such as vaginal discharge, vulvar pruritus, irritation, dysuria, abdominal pain and dyspareunia, no significant differences between the two treatments were seen after 10 to 15 days. After 30 to 35 days vaginal discharge, vulvar pruritus and irritation were significantly (p<0.001, 0.001 and 0.003 respectively) improved in the calendula group in comparison to clotrimazole [Saffari 2017].

Other effects
Case studies reported positive healing effects after application of not further characterized topical preparations in small diabetic lesions of the limbs, in exfoliative cheilitis or after periodontal surgery [Cioinac 2016; Roveroni-Favaretto 2009; Fang Mercado 2013].

Pharmacokinetic properties
In an *in vitro* assay on porcine ears, the skin penetration and percutaneous delivery of rutin and narcissin from a 50% ethanolic extract (yield 15.7%) in three topical formulations containing different excipients was studied. The compounds were absorbed. The amounts in viable skin and in the receptor phase depended on the composition of excipients in these formulations [Fonseca 2011].

Preclinical safety data

Acute toxicity
In the brine shrimp lethality assay, an ethyl acetate fraction (containing mainly flavonoids and phenolic acids), and a butanol fraction (containing mainly saponins), from a 70% methanol extract produced LC_{50} values of 60.1 and 50.2 mg/mL respectively [Mohamed 2015].

For an aqueous extract administered to mice, the intravenous LD_{50} was determined as 375 mg/kg b.w. and the intraperitoneal LD_{100} as 580 mg/kg [Manolov 1964].

For a hydroalcoholic extract (DER 1:1, 30% ethanol) the subcutaneous LD_{50} was 45 mg in mice and the intravenous LD_{50} was 526 mg/100 g in rats [Boyadzhiev 1965].

An ethylene glycol extract (DER 2:1) was non-toxic in albino mice after subcutaneous administration of 10 mL/kg [Russo 1972].

Swiss male mice did not show any behavioural changes after single oral doses of 0.5, 1, 2 and 3 g/kg b.w. of an extract (80% methanol; DER 6.25:1) [Ali 1999].

Single oral doses of a 70% ethanolic extract up to 5 g/kg b.w. did not cause deaths or any signs of toxicity in Wistar rats and albino Swiss mice [Silva 2007].

Oral administration of a dried decoction (prepared from 1 part drug with 3 parts water) to male and female Wistar rats at a dose of 2 g/kg b.w. remained without any signs of toxicity. Over a period of 14 days normal tendency in body weight gain was observed and after this time no changes in examined tissues were seen [Lagarto 2011].

After i.p. administration, the LD_{50} of a 70% ethanolic extract in mice was determined as 2.45 mg/kg b.w. [Elzorba 2016].

A 70% ethanolic extract (18.7% yield) at oral doses of 50, 300, 1000 and 2000 mg/kg b.w. did not produce any symptoms of toxicity or mortality in male Wistar rats [Banakar 2016].

Application of the hydrodistilled essential oil (yield 1.25%) on the shaved skin of Wistar rats under occlusion at doses of 2.5, 5 and 10 mL/kg b.w. for 24 hours did not result in any

mortalities, signs of toxicity, erythema or oedema up to 48 hours [Mishra 2018].

Subchronic toxicity
Oral treatment of male Wistar rats with a 70% ethanolic extract (0.025, 0.25, 0.5 or 1 g/kg b.w.) for 30 days did not result in any deaths or clinical and behavioural signs of toxicity. Haematological and biochemical parameters remained largely unchanged. Only a slight fluctuation in erythrocyte count, mean corpuscular volume, mean corpuscular haemoglobin and differential leukocyte counts ($p<0.05$) was observed in the groups receiving the three higher doses. A dose-dependent increase in blood urea nitrogen and ALT was also seen in these groups. Of all tissues investigated, only lung weight decreased ($p<0.05$). No histological changes were seen in heart, kidney and brain. Microscopic changes in the liver (centrilobular cells with acidophilic cytoplasm and heterochromatic nuclei etc.) were only seen after the highest dose [Silva 2007]. Similar results on haematological and biochemical parameters were observed earlier in the same set-up in female Wistar rats receiving the same extract at 0.25, 0.5 or 1 g/kg b.w. for 30 days. The weight of the investigated organs including lung did not change [Silva 2005].

Various strains of mice did not show signs of toxicity after oral treatment with an aqueous extract from laser-irradiated calendula flower (11 or 55 mg/kg b.w. daily for 30 days). The LD_{50} was 500 mg/kg. Rats tolerated 11, 55 and 500 mg/kg in the same experimental setup, the observed LD_{50} was 2.75 g/kg. The surviving animals did not show signs of toxicity during a 90 day observation period following treatment [Jiménez-Medina 2006].

During treatment of male Wistar rats with an ethanolic extract (0.1, 0.3 or 1 g/kg b.w. p.o.) for 4 weeks, a pronounced increase of water consumption and urine volume was observed in weeks 3 and 4 with the lowest dose. At the end of treatment, an increase of neutrophils and a decrease of lymphocytes were seen with 1 g of the extract (both $p<0.05$). Creatinine was augmented with 0.1 and 0.3 g; glucose was reduced in the same groups. Total proteins and albumin were reduced with 0.1 g of the extract (all significant, $p<0.05$) [Parente 2009b].

Male and female Wistar rats received 50, 250 or 1000 mg/kg/day of a dried decoction (prepared from 1 part drug with 3 parts water) with drinking water for 90 days. Food consumption and body weight gain were similar to control in all groups and no behavourial signs of toxicity were detected. After 28 days a significant increase in total leukocyte counts in females ($p<0.001$) and in neutrophils in males ($p<0.05$), as well as a decrease in lymphocytes in males ($p<0.01$) were observed. After 90 days erythrocyte and leukocyte counts were increased dose-dependently ($p<0.01$) in both sexes. A raise in blood clotting time occurred only in males. Variations in ALT and AST differed in both sexes and slight histological changes in the liver were observed [Lagarto 2011].

In Wistar rats, after topical application of the essential oil (2.5, 5 and 10 mL/kg b.w. daily) for 13 weeks, no mortalities, signs of abnormality, changes in food consumption or body weight were observed. Significant ($p<0.01$) changes in haemotological parameters, including white blood cell count, haemoglobin content and % lymphocytes, were mainly seen after the highest dose. In the groups treated with 5 and/or 10 mL/kg, there were significant ($p<0.01$) changes in biochemical parameters including ALP, AST, ALT, cholesterol, albumin and total protein [Mishra 2018].

Chronic toxicity
An aqueous extract was reported to be non-toxic in chronic administration to mice [Manolov 1965].

No symptoms of toxicity were observed after oral administration of an extract (solvent unspecified) at 0.15 g/kg b.w. to hamsters over 18 months and to rats over 21 months [Avramova 1988].

Mutagenicity and Carcinogenicity
In the Ames test using *Salmonella typhimurium* strains TA 1535, TA 1537, TA 98 and TA 100, a fluid extract (60% ethanol) was non-mutagenic at concentrations of 50-5000 µg/plate. With *Aspergillus nidulans* diploid strain D-30, genotoxic effects with mitotic crossing over and chromosome malsegregation were observed at higher concentrations of 0.1-1.0 mg/mL, at which a concentration-dependent increase of cytotoxicity also occurred. These findings were not confirmed *in vivo* in the mouse bone marrow micronucleus test; after oral administration of the extract at up to 1 g/kg b.w. for two days no increase in the number of micronucleated polychromated erythrocytes was observed [Ramos 1998].

In a somatic mutation and recombination test in *Drosophila melanogaster*, an infusion (20 g drug/100mL) and a dried tea concentrate (DER appr. 10:1), redissolved in water at concentrations of 20 and 40%, did not show any genotoxic effect [Graf 1994].

Carcinogenicity studies with calendula flower extract have been performed in rats over a period of 22 months and in hamsters over a period of 18 months with a daily oral dose of 0.15 g/kg body weight. The extract was not carcinogenic in either species [Avramova 1988].

Oral treatment of male Sprague-Dawley rats with 0.5g/kg of a dry ethanolic extract (not further specified) daily for 6 weeks produced no changes in DNA fragmentation or the level of the tumour marker AFP in the liver. Micronucleus formation in bone marrow cells as well as the expression of p53, Bax and Bcl-2 remained unchanged [Abdel-Aziem 2014].

Reproductive toxicity
A 70% ethanolic extract (30% yield; ≤0.4% flavonoids) was tested at oral doses of 0.25, 0.5 and 1.0 g/kg for 60 consecutive days on the reproductive function of Wistar rats. From day 53 to 60, rats were mated with untreated, fertile female rats. Reproductive parameters including testicular morphology, reproductive organ weights, fertility index and offspring viability were not affected as compared to control. In a second protocol, groups of pregnant rats were treated orally with the same doses from days 1 to 6 (preimplantation period), 7 to 14 (organogenic period) or 15 to 19 (foetal period) of pregnancy. The treatment was non-toxic in the preimplantation and organogenic periods. During the foetal period, a dose-dependent decrease of the maternal weight gain (significant at the highest dose; $p<0.05$) and of placental absolute weight, but not of placental relative weight ($p<0.05$) was observed as compared to control [Silva 2009].

Sensitizing potential
An oily extract from calendula was tolerable to mucosa in the Draize primary mucosa irritation test using the rabbit eye [Isaac 1992].

Various preclinical toxicological data, mainly from company reports, were compiled for three commercial extracts (1-5% in soybean oil; 10-25% in glycerol; unspecified amount in butylene and water) with a broad use in cosmetics [Anonymus 2001].

Clinical safety data
In a randomized study involving 156 patients with 2nd or 3rd degree burns a calendula ointment was significantly better tolerated ($p = 0.002$) than a proteolytic ointment [Lievre 1992].

No side effects or irritations were observed in 30 patients with

burns or scalds during treatment with a hydrogel containing 10% of a hydroethanolic extract 3 times daily for up to 14 days [Baranov 1999].

Topical treatment of patients with lower leg venous ulcers with a preparation containing an ethanolic extract did not result in systemic or local adverse effects [Duran 2005].

The three adverse reactions reported in 2,135 patients were skin and subcutaneous tissue symptoms, of which two occurred after application of combinations [Jeschke 2009].

No adverse effects were observed in 42 patients with recurrent vaginal candidiasis treated topically with an aqueous solution [Milián Vázquez 2010].

No adverse effects were reported in a study in 34 children with diaper dermatitis treated with an ointment containing 1.5% calendula flower extract three times daily for ten days [Panahi 2012].

In 120 patients with gingivitis using a mouthwash containing 25% of a tincture twice daily for six months, no adverse effects were observed [Khainar 2013].

In 41 patients with diabetic foot ulcers, no adverse events were observed during treatment with a spray solution containing 4% of a hydroglycolic extract [Buzzi 2016a].

In a very detailed safety assessment, it was concluded that calendula flower and its extracts are safe for use in cosmetics [Andersen 2010].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me, on behalf of my colleagues in ESCOP, to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index

URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

CARVI AETHEROLEUM 2019

Caraway Oil

DEFINITION

Caraway oil is obtained by steam distillation from the dry fruits of *Carum carvi* L.

The material complies with the monograph of the European Pharmacopoeia [Caraway oil].

CONSTITUENTS

Mainly oxygenated monoterpenes: (S)-(+)-carvone: 50 to 65%; *trans*-dihydrocarvone: up to 2.5%; *trans*-carveol: up to 2.5%; and monoterpene hydrocarbons: (*R*)-(+)-limonene: 30 to 45%; β-myrcene: 0.1 to 1.0% [Caraway oil; Samojlik 2010; Raal 2012].

CLINICAL PARTICULARS

Therapeutic indications

Internal use
Symptomatic relief of digestive disorders such as bloating, flatulence and spasm of the gastrointestinal tract [Martindale 2014; Sticher 2015; Stahl-Biskup 2016]. Flatulent colic of infants and children [BPC 1973; Dorsch 2002; Bradley 2006, Martindale 2014].

In these indications, efficacy is plausible on the basis of human experience and long-standing use.

External use
Flatulent colic of infants [Fintelmann 2009]. In this indication, efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Internal use
Adults:
3 to 6 drops daily in divided doses [BPC 1973, Fintelmann 2009, Schilcher 2010].

Children
Infants over 6 months:
2–3 drops concentrated caraway water (0.26 - 0.38 µL of caraway oil) [BPC 1973] for use in feeding bottles (equivalent to circa 60 mg caraway fruit) per day [Bradley 2006]
Children up to 1 year: 1–2 drops daily [Dorsch 2002]
Children from 1 to 4 years: 2-4 drops daily [Dorsch 2002]
Children above 4 years: 3-6 drops daily [Dorsch 2002]

External use
Children and adolescents: An ointment (2% w/w) to be applied once daily as a thin layer on the abdominal area after bathing in the evening.
Adults: 10% in olive oil, rub 10-12 drops onto the stomach [Weiss & Fintelmann 2000].

Method of administration
For oral administration or external application to the abdomen.

Duration of use
If symptoms persist or worsen, use should be discontinued and medical advice sought.

Contra-indications
Patients with known sensitivity to Apiaceae (Umbelliferae) should not use caraway oil and its preparations.

E/S/C/O/P MONOGRAPHS

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
In accordance with general practice the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties
Caraway oil acts as a carminative, spasmolytic, choleretic and cholagogue [Georg 2003; Mickelfield 2003].

In vitro experiments

Muscle relaxant / spasmolytic activity
Caraway oil had a relaxant effect on guinea pig tracheal muscle, decreasing the force of phasic contractions by 50% at 27 mg/L, but no antispasmodic effect was observed on electrically-stimulated guinea pig ileum. Caraway oil (20 – 60 mg/L) produced a marked increase in resting force (i.e. contracture) of the ileal mesenteric plexus- longitudinal muscle preparation [Reiter 1985].

The oil administered to isolated rat uterus inhibited the tonic contraction to KCl (80 mM) and the phasic contraction to ACh (320 nM) in a concentration-dependent manner [Sadraei 2003].

(*S*)-(+)-carvone and (*R*)-(+)-limonene produced relaxation in isolated guinea-pig ileum but were less potent than (*R*)-(-)-carvone [de Sousa 2008].

Smooth muscle contractility was evaluated using longitudinal strips isolated from the gastric fundus and duodenum of mice. Under Ca^{++}-free conditions, (*S*)-(+)-carvone (600 µM) significantly ($p<0.05$) inhibited both the phasic and tonic phases of carbachol (1 µM) - induced contractions and contractions caused by electrical field stimulation, indicating muscle relaxant and antispasmodic effects. Effects were more pronounced in duodenal tissues where 100 µM concentrations were also active [Silva 2015].

Antimicrobial activity
The MIC of caraway oil against *Helicobacter pylori* was found to be 0.03 % V/V (273.1 µg/mL) with an MBC of 0.06-0.125 % V/V (546.1-1092.2 µg/mL) in comparison with amoxicillin (MIC: 0.02 µg/mL), ampicillin (MIC: 0.064 µg/mL) and levofloxacin (MIC: 0.39 µg/mL) [Weseler 2005].

The oil was found to have antibacterial and antifungal activities. Gram-positive bacteria in general were more sensitive: *Bacillus cereus* (MIC = 0.5 µL/mL; MBC = 1.0 µL/mL); *Micrococcus luteus* (MIC = 1.0 µL/mL; MBC = 1.0 µL/mL); *Staphylococcus aureus* (MIC = 0.1 µL/mL; MBC = 0.25 µL/mL), than Gram-negative bacteria: *Escherichia coli* (MIC = 2.0 µL/mL; MBC = 4.0 µL/mL); *Proteus mirabilis* (MIC = 2.0 µL/mL; MBC = 4.0 µL/mL); *Pseudomonas tolaasii* (MIC = 4.0 µL/mL; MBC = 6.0 µL/mL); *Salmonella enteritidis* (MIC = 0.25 µL/mL; MBC = 0.5 µL/mL). Evaluation of antifungal activity against a series of micromycetes, found a concentration of 0.25 – 2.5 µL/mL inhibited their growth, except for *Trichoderma viride* when 10.0 µL/mL was effective [Simic 2008].

The oil displayed a high degree of antimicrobial selectivity, inhibiting the growth of potential pathogens associated with intestinal dysbiosis at concentrations that had no effect on the beneficial bacteria examined (*Lactobacillus acidophilus*, *L. plantarum*). MIC for *Candida albicans* was 0.55% V/V and 0.275% V/V for *Clostridium difficile* [Hawrelak 2009].

The antimicrobial activity of the oil was stronger against fungi than bacteria. The following MIC values were observed: *Aspergillus niger* (0.12%); *Penicillium expansum* (0.12%); *Saccharomyces cerevisiae* (0.06%); *Candida knusei* (0.06%); *Salmonella enteritidis* (0.12%); *E. coli* (0.12%); *S. aureus* (0.12%); *Bacillus subtilis* (0.12%). Results confirmed that the oil was more effective against Gram-positive than Gram-negative bacteria [Gniewosz 2013].

The antimicrobial activity of caraway oil differs, depending on the genotypes, ranging from MIC = 0.16 mg/mL to 1.75 mg/mL. A significant negative correlation was found between MIC and carvone content and a positive correlation with limonene content [Seidler-Lozykowska 2013].

Antioxidant activity
The antioxidant activity of caraway oil was measured in the DPPH assay. The oil reduced the DPPH in a dose-dependent manner. Effects on lipid peroxidation were determined by the thiobarbituric acid assay (TBA) assay. In the Fe^{2+}/ascorbate system the oil expressed a strong and partly dose-dependent antioxidant capacity (IC_{50} of <2.5 µL/mL), with the highest inhibition (68.1%) at 5 µL/mL [Samojlik 2010].

Other effects
Foam height of simulated gastric juice was reduced by caraway oil at concentrations of 0.025 - 0.1% [Harries 1978].

De-sheathed sciatic nerves isolated from male Wistar rats were used to evaluate the effects of *R*-(-)- and *S*-(+)-carvone on inhibition of the compound action potential (CAP). Using a modified single sucrose-gap technique both enantiomers (at 10 mM) reduced peripheral nerve conduction (V_{CAP}) compared to control. *S*-(+)-Carvone produced an IC_{50} of 8.7+0.1mM. After 30 min of incubation *S*-(+)-carvone inhibited the CAP amplitude to about 25% of control reducing from 39.4+ 2.0 mV to 9.8+3.0 mV ($p<0.05$) and then reverted to 29.9+1.6 mV after 30 min nerve washing with the vehicle. Carvone may decrease nerve excitability by blocking voltage-gated sodium channels in a reversible manner. (+)-limonene (10mM) had no CAP-blocking effect [Goncalves 2010].

The effect of (+)-carvone on glutamatergic spontaneous excitatory postsynaptic currents (sEPSCs) was examined in substantia gelatinosa (SG) neurons of adult rat spinal cord slices by using the whole-cell patch-clamp technique. The stereoisomers (+)- and (-)-carvone were found to activate different types of TRP channels. The (+)-carvone (1mM) activity was inhibited by the TRPA1 antagonist HC-030031, indicating activation of TRPA1 channels, resulting in an increase in spontaneous L-glutamate release into SG neurons. The EC_{50} value for this activation was 0.72 mM [Kang 2015].

In vivo experiments

Anti-colitic activity
Caraway oil was given to groups (n=6) of male Wistar rats orally (100, 200, 400 µL/kg) or intraperitoneally (100, 400 µL/kg) 6 hours after induction of trinitrobenzene sulfonic acid (TBNS)-induced colitis and daily for 5 consecutive days. Colon tissue lesions (ulcer areas) and colitis indices were significantly reduced ($p<0.001$) in all cases in comparison to control groups, irrespective of dose and route of administration [Keshavarz 2013].

Anti-carcinogenic activity
Premalignant lesions were induced in rat colon by administration of 1,2-dimethylhydrazine (DMH; 20 mg/kg b.w. for 5 weeks). Rats given caraway oil (0.01 and 0.1% in the diet) for 16 weeks showed a suppression of DMH-induced lesions (72–87%) when compared to controls. Results indicated that long-term feeding of caraway oil altered colonic CYP1A1 and GST activities and the expression of β-catenin (a dual-function protein, which regulates the coordination of cell–cell adhesion and gene transcription) [Dadkhah 2011; Allameh 2013]. In a further experiment with DMH-treated rats given caraway oil (0.2% in the diet), a significant inhibition of colonic β-catenin was shown. A 65% inhibition ($p<0.05$) of aberrant crypt foci (ACF) formation was also reported. In addition, a significant reduction of hepatic CYP450 activity ($p<0.05$) and increase of GST ($p<0.05$) in DMH-treated rats were shown, when compared to the DMH-treated control group [Dadkhah 2014].

Effects on central nervous system
The effect of chirality on locomotor activity (LA) was evaluated in mice pre-treated with analeptics (amphetamine, methamphetamine, caffeine) and sedatives (diazepam, phenobarbital). Results were dependent on the chirality of the terpene and the circadian rhythm of mice. Inhalation of (*S*)-(+)-carvone by 'morning' mice (i.e. 'highly-active') produced a stimulating effect with phenobarbital-treatment ($p<0.05$) but a decreased LA in over-stimulated animals (with caffeine $p<0.05$) [Buchbauer 2005].

(*S*)-(+)-carvone (200 mg/kg i.p.) given to mice produced a depressant effect in the CNS and had anticonvulsant-like activity [De Sousa 2007].

Mice treated with methylphenidate (5 mg/kg i.p.) or sleep-deprived for 24 h exhibited an increase in locomotor activity. Single dose acute pre-treatment and chronic treatment once daily for 3 weeks with 100 mg/kg i.p. of (*S*)-(+)-carvone significantly ($p<0.05$) reduced methylphenidate-induced hyperlocomotion compared to a saline control group. Lithium (100 mg/kg), used as a positive control, showed significant activity with chronic treatment. Acute pre-treatment with (*S*)-(+)-carvone and lithium at the same doses significantly ($p<0.001$) blocked sleep deprivation-induced hyperlocomotion. Spontaneous locomotor activity was not significantly altered by (*S*)-(+)-carvone (50 or 100 mg/kg) or lithium (100 g/kg) in the first experiment; in the sleep deprivation experiment a non-sleep deprived control group given (*S*)-(+)-carvone (100 mg/kg) did exhibit a significant ($p<0.05$) reduction in spontaneous locomotion [Nogoceke 2016].

Effects on gastrointestinal motility
The effects of (*R*)-(-)- and (*S*)-(+)-carvone (100 mg/kg dissolved in vehicle) on gut motility were evaluated in 'awake' mice by measuring gastric dye emptying and the rate of intestinal transit. Intragastric pressure was also monitored. Gastric emptying (expressed as % of dye) was significantly lower ($p<0.05$) in mice treated with (*R*)-(-)-carvone (32.1%) and (*S*)-(+)-carvone (41.9%), when compared to vehicle (control, 59.2%), but higher than the positive control loperamide (29.1%). Both enantiomers also significantly ($p<0.05$) delayed intestinal transit when the liquid test meal was injected directly into the duodenum, with effects being comparable to that produced by the positive control (loperamide). Spontaneous and rhythmic intragastric mean amplitudes of pressure waves were significantly ($p<0.05$) decreased by (*R*)-(-)-carvone (13.2 mmHg) and (*S*)-(+)-carvone (10.7 mmHg) when compared to vehicle alone (24.6 mmHg), but higher than loperamide (6.9 mmHg) [Silva 2015].

Other effects
Male albino rats (n = 30) were divided into 3 groups: control (A), diabetic positive control (B) receiving 60 mg/kg s.c. streptozotocin (STZ) for 3 days and the experimental group (C) receiving 60 mg/kg STZ s.c. for 3 days followed by 10 mg/kg/day p.o. caraway oil. After 22 days rats in group B showed an increase in serum glucose and a decrease in glutathione peroxidase. Caraway oil reduced these changes in rats of group C. Examination of the kidneys of group C rats showed minor pathological changes compared with group B rats where kidneys showed glomerular and tubular degeneration, with haemorrhage and deformed renal tissue architecture [Abou El-Soud 2014].

To assess hepatoprotective activity against CCl_4, 2 groups of NMRI mice (n=6 each) were pre-treated daily for 5 days p.o. with saline (control) or caraway oil (0.13 g/kg). 20 h before sacrifice animals were administered i.p. a single dose of CCl_4 in olive oil (1:1; 2 mL/kg), 4 h after the last dose of caraway oil. Pre-treatment with caraway oil prevented a pro-oxidative effect in liver tissue homogenate, despite increased peroxidase activity, while xanthine oxidase activity showed a statistically significant decrease ($p<0.05$ vs control). The oil pre-treated group given CCl_4 showed significant ($p<0.05$) increases in glutathione peroxidase (oil+CCl_4: 1.76 vs CCl_4:1.08 nmol/mg of protein/min). Plasma aspartate transaminase activity (U/L) rose significantly ($p<0.05$) compared to the saline control (oil+CCL_4:173 U/L vs CCl_4:229 U/L vs control 89 U/L). In spite of the CCl_4 potential to form lipid peroxidation products (LPx), the LPx remained unchanged in the oil-treated group compared to both control and CCl_4 groups [Samojlik 2010].

Carvone or limonene, both isolated from caraway oil, given by oral administration (3 times over 6 days) to mice (20 mg/animal) significantly increased ($p<0.05$ to $p<0.005$) glutathione *S*-transferase (GST) activity in the liver, forestomach, small intestinal mucosa and colon. Limonene was less effective [Zheng 1992].

Pharmacological studies in humans

Antispasmodic effect
Healthy volunteers (n=12) took a capsule containing caraway oil (50 mg) on an empty stomach, followed 15 mins later by a non-fat test drink (400 mL apple juice + 1 mL lactulose). Sonographic measurements showed that the gall bladder emptied in response to the drink. On refilling the gall bladder showed a volume increase of 90% (from initial) compared to 40% in the controls (test drink only) indicating that caraway oil had a relaxing effect on the gall-bladder without significantly prolonging orocaecal transit time [Goerg 2003].

The effect of an intraduodenal administration of caraway oil (50 mg) on gastroduodenal motility was studied in healthy volunteers (n = 7). Results showed significant reductions in contraction amplitudes of the duodenum ($p = 0.025$) as well as reduced contraction duration and amplitudes in the gastric corpus and antrum ($p = 0.028$), indicating smooth-muscle relaxing effects of the oil [Mickelfield 2003].

Effects on the central nervous system
The effects of chirality on the human autonomic nervous system were studied in healthy volunteers (n = 20). Inhalation of *R*-(+)-limonene increased systolic blood pressure, subjective alertness and restlessness, while *S*-(+)-carvone increased levels of both systolic and diastolic blood pressure [Heuberger 2001].

Clinical studies

Irritable bowel syndrome
In a monocentric, randomized, open-label, cross-over trial, 48 patients with Irritable Bowel Syndrome (IBS) were randomly assigned to one of 6 groups. Each group received, in different orders, three interventions: (i) hot caraway oil-containing poultice (2% solution in olive oil; CarO); (ii) hot olive oil poultice (OliveH) as control and (iii) cold olive oil (OliveC). Patients applied each intervention to their abdominal area daily for 3 weeks. By means of patient questionnaires symptom severity was measured using the IBS-symptom severity scale [Francis 1997]. A significant difference (p = 0.033) was found for symptom severity in favour of CarO compared to OliveC, but not compared to OliveH [Lauche 2015].

Pharmacokinetic properties

Pharmacokinetics in vitro
A membrane diffusion model was used to study the transfer of caraway oil (0.5 g) from a buffer solution pH 1.1 (= stomach) and pH 6.5 (= intestine) to pH 7.5 (= plasma). Only very low concentrations of carvone, *d*-limonene and other components (no amounts given) were transferred through the membrane [Lado 2005].

Gastrointestinal absorption
The absorption of carvone from a caraway fruit extract (1:3, ethanol 30% V/V) was tested in everted intestinal sacs prepared from male adult rats. After 30 minutes, the uptake from an extract concentration of 11.7µg/mL was about 3 µg/cm^2 carvone [Kelber 2000].

Percutaneous absorption
Caraway oil increased permeation of salicylic acid by 48% when evaluated using goat skin [Kaza 2006].

After a single topical application to an area of the lower abdomen (376 cm^2) of healthy subjects (n=4), *S*-(+)-carvone (300 mg in 1.5 g arachis oil) was rapidly absorbed (T_{max} (min) 32.4), resulting in a C_{max} of 88 ng mL^{-1} and distribution half-life ($t_{1/2\alpha}$) of 19.4 min [Jäger 2001].

Using human abdominal skin, (*R*)-(+)-limonene (5% V/V) was found to improve the permeability of haloperidol (2.5 mg/mL) by 26.5 times ($p<0.05$) and reduce the lag time from 14.1 to 9.2 h ($p<0.05$), compared to control [Lim 2006].

A terpene-based hydroxypropyl cellulose gel drug reservoir system was used to study the transdermal permeation of ondansetron hydrochloride through prepared rat epidermis. Carvone (8% m/m) produced an optimal permeation of 87.4 mg/cm^2·h ($p<0.001$) and limonene (3% m/m) of 181.9 mg/cm^2·h ($p<0.01$). The enhancement ratio in drug permeability was 10.8 with carvone and 22.5 with limonene, when compared with 1.0, i.e. that obtained without a terpene-enhancer (control) [Krishnaiah 2008].

Biotransformation
R-(-)- and *S*-(+)-carvone are stereoselectively biotransformed by human liver microsomes to 4(*R*),6(*S*)-(-)- and 4(*R*),6(*S*)-(+)-carveol respectively and 4(*R*),6(*S*)-(-)-carveol is further glucuronidated [Jäger 2000].

Pharmacokinetics in animals

Absorption, distribution, metabolism and elimination
The absorption rate of a caraway fruit extract (1:3, ethanol 30%) determined as carvone, was carried out using the mouse everted gut sac technique. Incubation time was 30 min and extract concentrations were 10, 25, 50 and 100 µL/mL. Data indicate a fast uptake of carvone linearly correlated to the mucosal concentration [Kelber 2006].

In rabbits, (*S*)-(+)- and (*R*)-(-)-carvone is reduced to yield carveol which is converted to the glucuronic acid conjugate and excreted in the urine [Ishida 1989].

The main route of elimination of (*R*)-(+)-limonene administered orally was via the urine in animals and man, 75-95% of the administered radioactivity being excreted in the urine during 2-3 days. Faecal excretion accounted for less than 10% of the dose in animals during 2-3 days. In addition to six metabolites, namely p-mentha-1,8-dien- 10-ol (M-I), p-menth-1-ene-8,9-diol (M-II), perillic acid (M-III), perillic acid-8,9-diol (M-IV), p-mentha-1,8-dien-10-yl-beta-D-glucopyranosiduronic acid (M-V) and 8-hydroxy-p-meth-1-en-9-yl-beta-D-glucopyranosiduronic acid (M-VI) isolated from rabbit urine previously, five new metabolites have been isolated from dog and rat urine, and which were characterized as 2-hydroxy-p-menth-8-en-7-oic acid (M-VII), perillylglycine (M-VIII), perillyl-beta-D-glucopyranosiduronic acid (M-IX), p-mentha-1,8-dien-6-ol (M-X) and probably p-menth-1-ene-6,8,9-triol (M-XI). The major metabolite of (*R*)-(+)-limonene in the urine was M-IV in rat and rabbit, M-IX in hamster, M-II in dog and M-VI in guinea pig [Kodama 1976].

Pharmacokinetics in humans
Oral administration of an immediate-release preparation containing peppermint oil (180 mg) and caraway oil (100 mg) to healthy male volunteers (n=15) yielded a mean C_{max} for carvone of 12.57 ng/mL, a mean T_{max} of 1.24 h and mean $t_{1/2}$ of 2.0 h [Mascher 2001].

(S)-(+)-Carvone

Percutaneous absorption
To determine whether an enantioselective difference in the metabolism of topically applied *R*-(-)- and *S*-(+)-carvone could be observed in man, the metabolism and pharmacokinetics of *R*-(-)- and *S*-(+)-carvone was investigated in four healthy subjects. Following separate topical applications at a dose of 300 mg, *R*-(-)- and *S*-(+)-carvone were rapidly absorbed, resulting in significantly higher C_{max} levels for (*S*)-(+)-carvone (88.0 vs 23.9 ng/mL) and longer distribution half-lives ($t_{(1/2\alpha)}$; 19.4 vs 7.8 min), resulting in 3.4-fold higher areas under the blood concentration-time curves (5420 vs 1611 ng x min/mL). The biotransformation products for both enantiomers in plasma were below detection limit. Analysis of control- and beta-glucuronidase pre-treated urine samples, however, revealed a stereoselective metabolism of *R*-(-)-carvone to 4*R*,6*S*-(-)-carveol and 4*R*,6*S*-(-)-carveol glucuronide. No metabolites could be found in urine samples after (*S*)-(+)-carvone application. These data indicate that stereoselectivity in phase-I and phase-II metabolism has significant effects on *R*-(-)- and *S*-(+)-carvone pharmacokinetics and could explain the increased blood levels of (*S*)-(+)-carvone [Jäger 2001].

Metabolism
Using the Metabolism Ingestion-Correlated Amounts (MICA) approach, volunteers (n=6) receiving a controlled diet were given a single dose of (*S*)-(+)- or (*R*)-(-)- carvone (0.5 mmol; ~ 1 mg/kg b.w.) ingested as a solution in full-fat milk (500 mL). 24-hour urine samples were collected before (control) and after

ingestion of carvone. Carvonic acid, dihydrocarvonic acid, carveol, dihydrocarveol and uroterpenolone were identified as the metabolites in humans. 10-Hydroxycarvone was not detected, indicating either concentration effects or interspecies differences. No differences in metabolism between (*S*)-(+)- and (*R*)-(-)-carvone were detected [Engel 2001].

Lactation/Breast milk
Lactating women (n=18) were each given 100 mg of (*S*)-(+)-carvone mixed with lactose and talc in a capsule on 3 test days. Milk samples were collected every 2 hours for 8 hours starting at the time of ingestion. Carvone was detected in milk at all times, with the average concentrations of 1.3 µg/L at 0 hours, reaching a maximum of 7.2 µg/L at 2 hours, 5.6 µg/L at 4 hours, 4.3 µg/L at 6 hours and 2.7 µg/L at 8 hours. The average peak carvone concentration in milk was 10.5 µg/L. It is considered that lipophilic flavour compounds are transported from blood into milk via passive diffusion [Hausner 2008].

In another study, 20 mothers consumed 30 mg of (*S*)-(+)-carvone in 75 grams of hummus every third day for 28 days (10 exposures) at about 2 hours before a "usual" nursing time. Breastmilk samples were obtained 2 hours after ingestion on the first and last days of carvone intake. Carvone was detectable in the milk of 18 mothers. Average carvone concentrations in breastmilk were 2.5 µg/L and 3.8 µg/L on the first and last days of sampling, respectively. However, these values did not differ statistically and the combined average carvone concentration was 3.2 µg/L. A control group of 20 women who did not ingest (*S*)-(+)-carvone had no detectable carvone in their breastmilk [Hausner 2010].

(R)-(+)-Limonene
About 25-30% of an oral dose of (*R*)-(+)-limonene in humans was found in urine as (*R*)-(+)-limonene-8,9-diol and its glucuronide; about 7-11% was eliminated as perillic acid and its metabolites [Kodama 1976].

Healthy human volunteers (n=7) ingested 100 mg/kg limonene. Blood was drawn at 0 and 24 h for chemistry-panel analysis and at 0, 4, and 24 h for limonene-metabolite analysis.Atleast five compounds were present at 4 h that were not present at time zero. Two major peaks were identified as dihydroperillic acid and perillic acid, and two minor peaks were found to be the respective methyl esters of these acids. A third major peak was identified as limonene-1,2-diol. Limonene was a minor component. At a dose of 100 mg/kg, limonene caused no gradable toxicity [Crowell 1994].

In a single centre, open-label pharmacokinetic study, healthy male volunteers (n=24) were given a single dose of 300 mg (*R*)-(+)-limonene with 240 mL water. The maximum plasma concentration of (*R*)-(+)-limonene ranged from 40.1 to 327.4 ng/mL. T_{max} values ranged from 0.75 to 3.0 h and oral clearance ranged from 53.7 to 312.1L/h [Wang 2007].

Patients (n=32) with refractory solid tumours completed 99 courses of (*R*)-(+)-limonene 0.5 to 12 g/m^2 per day administered orally in 21-day cycles. Additional breast cancer patients (n=10) received 15 cycles of (*R*)-(+)-limonene at 8 g/m^2 per day. One partial response in a breast cancer patient on 8 g/m^2 per day was maintained for 11 months; three patients with colorectal carcinoma had prolonged stable disease. There were no responses in the phase II study. Peak plasma concentration (C_{max}) for (*R*)-(+)-limonene ranged from 10.8+6.7 to 20.5+11.2 mM. Predominant circulating metabolites were perillic acid (C_{max} 20.7+13.2 to 71+29.3 mM), dihydroperillic acid (C_{max} 16.6+7.9 to 28.1+3.1 mM), limonene-1,2-diol (C_{max} 10.1+8 to 20.7+8.6 mM), uroterpenol (C_{max} 14.3+1.5 to 45.1+1.8 mM), and an isomer of perillic acid. Both isomers of perillic acid, and cis- and trans- isomers of dihydroperillic acid were in urine hydrolysates. Intratumoural levels of (*R*)-(+)-limonene and uroterpenol exceeded the corresponding plasma levels. Other metabolites were trace constituents in tissue [Vigushin 1998].

Preclinical safety data

Allergenicity
In a 24-hour closed-patch test in humans a 4% concentration of caraway oil in petroleum jelly produced no irritation [Opdyke 1973].

The Scientific Committee on Consumer Safety [SCCS] on fragrance allergens in cosmetic products has listed carvone among the established contact allergens (skin sensitisers) in humans [EFSA 2014].

Although the non-oxidized *R*-(+)-limonene itself is not allergenic, it easily forms allergenic autoxidation products. A limonene hydroperoxide fraction proved to be the most important allergen of the oxidation mixture, showing positive reactions in around 60% of the limonene-allergic patients. Testing limonene oxide and carvone separately resulted in very few positive reactions. In Europe, *R*-(+)-limonene containing oxidation products are classified as a skin sensitizer in animals and humans [Matura 2002; 2003; Kim 2013].

Acute toxicity
The oral LD_{50} for caraway oil in rats is 3.5 mL/kg b.w. corresponding to 3720 mg/kg b.w. [EMEA 1998] and 3500 mg/kg; LD_{50} for rabbit skin 1780 mg/kg [Lewis 1996].

LD_{50} value for (*S*)-(+)-carvone in mice was 484.2 mg/kg [De Sousa 2007].

The EFSA Scientific Committee established an Accepted Daily Intake (ADI) for (*S*)-(+)-carvone of 0.6 mg/kg b.w./day, based on the $BMDL_{10}$ of 60 mg/kg b.w./day for an increase in relative liver weight in the rat, 90-day studies and an uncertainty factor of 100 [EFSA 2014].

The oral LD_{50} for *R*-(+)-limonene in male and female mice is reported to be 5.6 and 6.6 g/kg b.w. respectively, and 4.4 and 5.1 g/kg b.w. in male and female rats respectively [IARC 1999].

Administration to rats and mice of *R*-(+)-limonene at doses ranging from 413 - 6,600 mg/kg/day for 5 days/week for 3 weeks, resulted in no signs of compound-related toxicity at doses <1,650 mg/kg daily [NTP 1990b].

The dose-response for *R*-(+)-limonene has shown NOEL of 3.6 mg/kg/day in the development of hyaline-droplet nephropathy in male rats and no development of kidney tumours are expected to occur in male rats below this NOEL. Neither female rats nor mice developed tumours or hyaline-droplet nephropathy, which is associated with elevated alpha2u-globulin as found in male rats. *R*-(+)-limonene is stated as not posing a risk to humans for the formation of renal neoplasms [Whysner 1996].

Subchronic and chronic toxicity
A study in rats demonstrated that 0.1% carvone in their diet for 28 weeks and 0.25% for one year had no effects, while 1% of (*S*)-(+)-carvone in the diet for 16 weeks caused growth retardation and testicular atrophy [EMEA 1998; Hagan 1967].

Based on short-term and long-term toxicity studies in rodents, including a NOEL of 93 mg/kg b.w./day in rats, the World Health Organization established the ADI for (*S*)-(+)-carvone of 0-1 mg/kg b.w. per day [WHO 1999].

For (*S*)-(+)-carvone a daily intake of 1 mg/kg b.w. was considered harmless. For a 60 kg person this corresponds to a dose of 60 mg, approx. equivalent to 120 mg caraway oil (corresponding to approx. 6 drops) [EMEA 1998].

Mutagenicity and carcinogenicity
(*S*)-(+)-Carvone was not mutagenic in *Salmonella typhimurium* strains TA 98, TA 100, TA 1535 and TA 1537, with and without metabolic activation [EMA 1998].

(*S*)-(+)-Carvone was reported to be non-carcinogenic in a 103-week study in mice dosed with oral doses of 375 and 750 mg/kg b.w., 5 days per week [NTP 1990a; EMA 1998; EFSA 2009].

R-(+)-Limonene was not mutagenic in four strains of *S. typhimurium* (TA98, TA100, TA1535, or TA1537), did not significantly increase the number of trifluorothymidine (Tft)-resistant cells in the mouse L5178Y/TK&plusmn assay and did not induce chromosomal aberrations or sister chromatid exchanges (SCEs) in cultured CHO cells [NTP 1990b].

R-(+)-Limonene was administered by gavage to F344/N male rats for 5 days per week for 103 weeks at doses of 0, 75 or 150 mg/kg, and female F344/N rats at doses of 0, 300 or 600 mg/kg. There was no evidence of carcinogenic activity of *R*-(+)-limonene for the female rats that received 300 or 600 mg/kg. Evidence of carcinogenic activity was found only in male F344/N rats as shown by increased incidences of tubular cell hyperplasia, adenomas and adenocarcinomas of the kidney [NTP 1990b]. Similarly there was no evidence of carcinogenic activity of limonene for male B6C3F1 mice that received 250 or 500 mg/kg or female B6C3F1 mice that received 500 or 1,000 mg/kg [NTP 1990b]. Renal toxicity of limonene results from the accumulation in male rat kidney proximal tubule lysosomes of alpha-2u-globulin, a protein synthesized exclusively by adult male rats [Whysner 1996].

Male Big Blue ™ rats were given limonene (525 mg/kg) as part (1%) of their diet for 10 consecutive days. The rat carcinogen 4-aminophenyl was used as positive control. Limonene failed to increase the mutant frequency in the rat liver or kidney, results consistent with a non-genotoxic mechanism of carcinogenic action [Turner 2001].

R-(+)-Limonene has demonstrated no gradable toxicity in humans after single (100 mg/kg) [Crowell 1994] and repeated dosing (0.5-12 g/m^2/day for 21 days) with one person receiving 15 g/day for 11 months [Vigushin 1998; Sun 2007].

Clinical safety data

Safety of a standardized preparation of enteric coated capsules containing 90 mg peppermint oil and 50 mg caraway oil per capsule was studied in a double-blind, placebo-controlled multicentre trial in patients with non-ulcer dyspepsia. The test preparation was well tolerated, even over a 4-week period [May 1996; Madish 1999].

A second double-blind, randomized, parallel-group evaluation of the fixed peppermint oil/caraway oil combination vs placebo was carried out in patients suffering from functional dyspepsia (n=96). Patients received one capsule twice daily of the combination or placebo for 28 days. No side effects were reported by patients receiving the verum [May 2000].

In further randomized, placebo-controlled, double-blind clinical trials with the same combination (2 x 1 capsule daily), the test preparation did not show any adverse events [Holtmann 2001; Holtmann 2003].

R-(+)-Limonene has been found to be safe, when 100 mg/kg (equivalent to about 7 g for an average adult male) was ingested. Only mild eruction for 1-4 h, mild satiety for 10 h and mild fatigue for 4 h were reported [Crowell 1994].

In a dose-escalation study in patients (n=32) with refractory solid tumours, *R*-(+)-limonene (0.5 – 12 g/m^2/day) was given orally for 21 days. The maximum tolerated oral dose was 8 g/m^2/day (15 g/day). Nausea, vomiting and diarrhoea were observed and effects were dose-dependent. *R*-(+)-Limonene was considered to have low toxicity after single and repeated doses for up to one year [Vigushin 1998].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)

iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

CARYOPHYLLI AETHEROLEUM 2014

Clove oil

DEFINITION

Clove oil is obtained by steam distillation of the dried flower buds of *Syzygium aromaticum* (L.) Merrill et L.M. Perry (*Eugenia caryophyllata* (C. Spreng., Bull. et Harr.). The material complies with the monograph of the European Pharmacopoeia [Clove oil].

CONSTITUENTS

The main characteristic constituents of the essential oil are β-caryophyllene (5 - 14 %) and phenylpropanoids eugenol (75 - 88 %) and acetyleugenol (4 – 15 % of the oil); minor constituents, less than 1%, are 2-heptanone, ethyl hexanoate, humulenol; sesquiterpenes, α-humulene, α-humulene epoxide, β-humulene, β-caryophyllene oxide, α-cubebene, α-copaene, α-cadinene, δ-cadinene, α-ylangene, calacorene and calamenene [Clove oil; Iwamuro 1983; Gopalakrishnan 1984,1985; Zheng 1992; WHO 2002; Chaieb 2007; Blaschek 2008].

CLINICAL PARTICULARS

Therapeutic indications
In dental healthcare, for short term use, as a local anaesthetic [Leung 1980; Reynolds 1989], as a disinfectant mouthwash [Wichtl 2002; Bradley 2006; Blaschek 2008]. In these treatments the efficacy is plausible on the basis of human experience and longstanding use.

Symptomatic treatment in chronic anal fissure, after diagnosis by a physician [Elwakeel 2007].

Posology and method of administration

Dosage

Adult daily dose
As a mouthwash with 1-3% diluted clove oil, up to three times daily [Tisserand 1995; Wichtl 2002; Bradley 2006; Lis-Balchin 2006; Blaschek 2008].
For anorectal use: clove oil in a 1% cream, applied three times daily [Elwakeel, 2007].

Method of administration
Oromucosal or anorectal applications with liquid or semisolid preparations of clove oil [Markowitz 1992; Wichtl 2002; Elwakeel 2007; Blaschek 2008].

Duration of use
No restrictions. If symptoms persist or worsen medical advice should be sought.

Contraindications
Topical use of clove oil is contraindicated in case of hypersensitivity to clove oil, as well as hypersensitivity to Peru balsam due to possible cross reactivity. Of 78 patients with allergy to Peru balsam, 36 showed a positive reaction to clove powder [Niinimäki 1984]. Four out of 4 patients sensitized to Peru balsam reacted positive to a 1% hexane extract of clove in petrolatum [Bouhlal 1989].

Special warnings and special precautions for use
None required.

Interaction with other medicinal products and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

E/S/C/O/P MONOGRAPHS

Effects on ability to drive and use machines
None known.

Undesirable effects
Very rare cases of contact dermatitis and food allergy have been reported for clove oil or eugenol.

Investigations on contact allergy from essential oils were conducted by the Information Network of Departments of Dermatology (IVDK). In patch test results (from the years 2000 to 2008) of 15,682 patients with dermatitis (from 84,716 consulting), there were 637 cases positive for any oil: of these, 1.5% were positive for clove oil [Uter 2010].

In a worldwide, multi-centre investigation of allergy to cosmetics and toiletries, 43 (19%) of 218 subjects with proven contact dermatitis due to fragrance materials tested positive for clove oil (10% solution) in a new patch test [Larsen 2002].

In 589 cases of food allergy, none were allergic to clove [Moneret-Vautrin 2002].

45 patients occupied in stomatological services (dentists, dental surgeons, nurses and dental technicians), presenting with contact dermatitis of various unknown causes, were exposed to 17 potential allergens, including eugenol. Eugenol (1% solution) tested positive in 9% of the cases (3 dentists and 1 dental surgeon) [Berova 1990].

Allergic contact dermatitis was documented during a 5-year investigation. Only 1 of 1000 patients, working with food and diagnosed to have hand dermatitis, was found to be allergic to clove and simultaneously to carrot and allspice [Kanerva 1996]. Occupational allergic contact dermatitis from eugenol, oil of cinnamon and oil of cloves was reported in a physiotherapist [Sanchez-Perez 1999].

A survey of consumer patch-tests to investigate sensitization demonstrated a very low sensitization potential for eugenol. In 11,632 patch tests only 2 positive eugenol tests were detected at a concentration of 0.05 % (induced hypersensitivity) and at 0.09 % (pre-existing sensitization) [Rothenstein 1983].

Overdose, cutaneous and oral
Permanent local anaesthesia and anhidrosis was reported 11 months after an unknown amount of clove oil was spilled on the face of a patient with toothache. The symptoms were considered to be a neurotoxic effect after cutaneous use [Isaacs 1983].

Toxic effects were reported after oral overdoses of clove oil. Two children, that ingested overdoses of clove oil of 1 teaspoon (7 mo. old, corresponding to approx. 0.5 g/kg body weight of eugenol) and 10 ml (2 yr. old), presented with CNS depression and liver failure, respectively; both recovered [Lane 1991; Brown 1992]. After drinking 5-10 ml clove oil a young child presented with coma and acute liver damage, but recovered [Hartnoll 1993]. Fulminant hepatic failure was reported for a 3-month old patient after ingesting less than 8 ml clove oil, and for a 15 month-old boy after ingesting 10-20 ml clove oil. Both were successfully treated with intravenous N-acetylcysteine, according to a standard protocol used for paracetamol (acetaminophen) poisoning [Eisen 2004; Janes 2005].

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In view of the vast amount of scientific literature on clove oil and eugenol, the selection of literature cited in the following sections is aimed solely at bringing together relevant examples of the possible physiological roles of clove oil and its major constituents eugenol and β-caryophyllene.

Several monographs and reviews have described pharmacological and other properties of clove oil and/or eugenol, its isolated major constituent [Deininger 1991; Markowitz 1992; Tisserand 1995; Lis-Balchin 2006; Chaieb 2007; Edris 2007; Blaschek 2008].

In vitro experiments

Antibacterial activities (Table 1)
Reports on multiple antimicrobial activities of clove oil and other essential oils have been reviewed [Kalemba 2003; Ceylan 2004; Baser 2009]. The antibacterial activity of clove oil compares in magnitude with oils from spices with the highest antibacterial properties, such as the oils of thyme, cinnamon, oregano and rosemary. In direct comparison, clove oil exhibited slightly greater antibacterial activity than that of rosemary oil. For example, *Escherichia coli* was inhibited at 0.125 %V/V (MIC) by clove oil, as compared to 0.250 %V/V (MIC) by rosemary oil [Ceylan 2004; Prabuseenivasan 2006; Fabio 2007; Fu 2007].

Mechanism of antibacterial action
Eugenol at 1% V/V (MIC of 0.0125%) increased permeability of the bacterial cell membrane of *Salmonella typhi* and caused disruption of the cytoplasmic membrane [Devi 2010]. Clove oil had an antibacterial effect on *Propionibacterium acnes* (MBC/MIC 0.31 mg/mL). Loss of the bacterial membrane integrity, i.e. ruptured cell walls and membranes, resulted at 0.031-0.62 mg/mL clove oil, measured by flow cytometry [Fu 2009].

Antibiotic–resistant bacteria in hospital isolates
Clove oil was shown to be effective against hospital-acquired isolates of Methicillin-resistant *Staphylococcus aureus* (MRSA) and was proposed, together with other essential oils, for antiseptic topical treatment [Warnke 2009]. Inhibition zones of 26 multi-resistant *Staphylococcus epidermidis* strains, isolated from dialysis biomaterial in the hospital, were in the range of 11-15 mm, five strains had zones >16 mm [Chaieb 2007]. Eugenol was active against the antibiotic-resistant bacteria, *Klebsiella pneumonia*, *Shigella ssp*. and *Proteus ssp*. [Nascimento 2000].

Synergistic and additive antibacterial effects
Synergistic interactions of eugenol with antibiotics against Gram-negative bacteria were reported in a model for antibiotic-resistant bacteria [Hemaiswarya 2009]. Combinations of clove oil and rosemary oil have produced mostly additive and rarely synergistic or even antagonistic effects [Fu 2007].

A selection of reported antibacterial activities of clove oil and eugenol against a series of oral, respiratory and antibiotic-resistant pathogens, Gram-positive as well as Gram-negative bacteria, is presented in Table 1. For the MIC values shown, those representing a strong antibacterial effect are in the range of 0.01% - 0.25% V/V.

Antifungal activities (Table 2)
Selected information about antifungal properties of clove oil is presented in Table 2. 48 h-Biofilms of *Candida albicans* were inhibited by eugenol treatment at 0.047 % V/V (IC_{50}) and at 0.188 % V/V (IC_{80}), using the tetrazolium salt reduction assay [He 2007].

Clove oil exhibited, in comparison, a slightly higher antifungal activity than rosemary oil. For example, *Candida albicans* was inhibited at 0.125 %V/V (MIC) by clove oil, as compared

to 0.250 %V/V (MIC) by rosemary oil [Fu 2007]. Clove oil was effective against isolates from hospitalised patients with antimycotic-resistant *Candida* species, *C. albicans* and *C. krusei* [Warnke 2009].

Mechanism of antifungal action
Clove oil and eugenol both exhibited antifungal activity towards various *Candida*, *Aspergillus* and dermatophyte species, and against fluconazole-resistant strains (MFC's ranged at 0.32-1.25 µl/mL and MIC's at 0.16-1.25 µl/mL). The fungicidal effect at concentrations just above the MIC values, measured by penetration of propidium iodide, resulted in extensive lesions of the fungal cell membrane and reduced ergosterol in the membrane [Pinto 2009].

The mode of action for the antifungal effects of clove oil and eugenol on the fungal virulence of *Aspergillus niger* and *Trichophyton rubrum* was investigated by measuring elastase and keratinase activitiy. Eugenol and clove oil inhibited fungal elastase by up to 78% and 68% respectively. Keratinase was slightly inhibited by both. Since proteinases contribute to fungal virulence by destroying host tissues and digesting immunologically important proteins, such as antibodies and complement factors, the anti-proteinase activity may reduce the pathogenesis of fungi [Khan 2011].

Antiviral activity
The lipid envelope of *Herpes simplex* virus type 1 and Newcastle disease virus has been destroyed by clove oil (1/500 dilution;0.2 %V/V) and replication inhibited. Non-enveloped viruses (*adenovirus*-3 and *poliovirus*-S) were not affected by clove oil [Siddiqui 1996]. Antiviral activity was exhibited by eugenol at 149.5 µg/ml (0.016 % V/V) for 2 isolated strains of *Herpes simplex* virus-1, however this concentration did not inactivate a standard HSV-1 strain. Eugenol reduced virus HSV-2 replication by 16.5 -100 % [Tragoolpua 2007].

Anti-inflammatory properties
A scintillation proximity-based assay demonstrated inhibition of COX-2 by eugenol (IC_{50} = 129 µM) [Huss, 2002]. COX-2 gene

expression and PGE_2 production were inhibited by eugenol (IC_{50} = 0.37 µM) in mouse macrophages [Kim SS, 2003]. Eugenol inhibited 5-lipoxygenase activity (IC_{50} = 26 µM) and leukotriene C_4 formation (IC_{50} = 30 µM) by stimulated Human PMN (polymorphonuclear neutrophils) [Raghavenra 2006].

Induction of apoptosis
Reactive oxygen species-mediated apoptosis was induced by eugenol at 40 µM in HL-60 leukemia cells. Eugenol (at 700µM for 50% loss of viability) was also reported to induce apoptosis in mast cells, an indication of its anti-allergic potential. It is suggested that eugenol induces apoptosis *in vitro* by depleting intracellular thiols [Park 2005; Yoo 2005].

In vivo experiments

Clove oil, and its major constituents eugenol and β-caryophyllene, have been investigated for their local anaesthetic, antibacterial, antifungal, antioxidant, immunomodulatory, anti-allergic and insect repellent activities.

Antibacterial activity
Bacterial (*Klebsiella pneumonia*) colonization of the lungs was decreased ($p<0.01$) after 15 days of feeding with clove oil (0.5 mL of 1% w/v oil, once daily), when compared to control mice given saline 0.5 mL [Saini 2009].

Antifungal activity
To immunosuppressed rats with artificial vaginal candidiasis, 500 µL eugenol (equivalent to 2-fold MIC; approx. 20 mg/kg per day) was applied twice daily by topical intravaginal route (as prophylactic treatment, from 2 days before until 3 days after inoculation with *C. albicans*) and was compared to the effect of nystatin and further controls. Prophylactic eugenol reduced the colony count of *C. albicans* in vaginas of infected rats by 98.9% 10 days after inoculation, with negative culture results in 2/9 rats and significantly lower levels in 7/9 rats compared to control. In a second experiment, treatment with 500 µL eugenol

began 3 days after inoculation and was continued for 7 days. Two of 9 rats were cured completely and 7/9 showed an 84% reduction of the *C. albicans* colony count in the vagina. The positive control, nystatin, used at 10-fold MIC, confirmed the validity of the rat model [Chami 2004].

In the immunosuppressed (dexamethasone/tetracycline treated) rat model of experimental oral candidiasis, topical treatment in the oral cavity, twice daily with 0.5 mL of 0.4% eugenol dispersed in viscous 0.8% agar solution (20µg/kg/d), was started 3 days post-infection and continued for 8 days. Eugenol significantly ($p<0.05$) reduced the number of colonies sampled from the oral cavity, compared to the number of colonies in untreated rats. Nystatin was similarly effective and confirmed the fungicidal effect of eugenol [Chami, Bennis 2005].

Mice with an artificial urogenital infection were treated successfully with clove oil. Vaginal administration of a liposome preparation of clove oil, on days 2, 4, 6 and 8 after intra-vaginal inoculation with *Candida albicans*, was nearly as effective as a liposome preparation of nystatin in eliminating the fungal infection. Both the clove oil and nystatin formulations reduced the vaginal titre of *C. albicans* in vaginal lavage fluid significantly, when tested on day 10 against a negative control ($p<0.001$). At 14 days post-infection topical clove oil had completely eliminated the fungal burden in treated mice [Ahmad 2005].

Anti-anaphylactic, anti-allergic potential and immunomodulatory activity
Intraperitoneal treatment with eugenol at 50-100 mg/kg provided protection against PAF-induced shock from i.v. carrageenan-induced rat paw oedema in rabbits ($p\leq0.001$) [Saeed 1995].

In rats with chemically-induced anaphylactic shock, eugenol was anti-anaphylactic at an intraperitoneal dose of 10 mg/kg b.w. Accordingly, in rat peritoneal mast cells, histamine release and TNF-α production were reduced *in vitro* by eugenol at 10µg/mL [Kim 1997].

Immunomodulatory functions of clove oil were tested in mice (previously immunized with sheep red blood cells) after oral treatment once daily for 7 days with 100, 200 and 400 mg/kg clove oil. The oil increased the white blood cell count and also enhanced delayed-type hypersensitivity significantly ($p<0.001$ for all doses). It restored cellular and humoral immune reponses in cyclophosphamide-immunosuppressed mice in a dose-dependent manner ($p<0.001$ for 200 and 400 mg/kg) [Carrasco 2009].

Eugenol (at 700µM and at 10 µg/kg b.w.) was considered to exhibit an anti-allergic potential, resulting from induction of apoptosis in mast cells of rats (*in vitro* and *in vivo* respectively) [Park 2005].

Antioxidant activity in an aflatoxicosis rat model
Rats fed an aflatoxin-contaminated diet were either treated orally with clove oil (5 mg/kg b.w.) or untreated, for 30 days. Resulting haematological and biochemical changes were typical for aflatoxicosis. Clove oil treatment resulted in protection against aflatoxicosis, i.e. significantly restored ($p<0.05$) parameters that were altered by aflatoxin in rats [Abdel-Wahhab 2005].

Anaesthetic use
In the rabbit conjunctival reflex test, local β-caryophyllene treatment, by drops into the conjunctival sac, permitted a concentration-dependent increase of the number of stimuli necessary to provoke the reflex during 5-15 minutes after application, at 10-1000 µg/mL. In a comparative test, chemically related caryophyllene oxide, at 3-1000 µg/mL was ineffective. Thus β-caryophyllene acted as a specific local anaesthetic to the rabbit eye [Ghelardini 2001].

Eugenol produced reversible dose-dependent (i.v. administration of single doses at 5-60 mg/kg) anaesthesia. The anaesthetic level was determined using the withdrawal reflex test by pinching the rats until the return of a positive response. Eugenol-induced loss of consciousness, in a dose–dependent manner, showed a mean recovery time of 167 +/- 42 sec at the highest dose level [Guenette 2006]. Induced thermal hypersensitivity was attenuated in rats treated with 40 mg/kg eugenol for 5 days ($p<0.01$) [Guenette 2007].

Gastroprotective activity
Clove oil and eugenol both displayed anti-ulcer activity. Gastroprotective effects were observed after intraduodenal administration of clove oil and eugenol (100 and 250 mg/kg) in rat models of indomethacin- and ethanol-induced ulcers. At the same doses, eugenol and clove oil also stimulated the production of mucus ($p<0.01$), an important gastro-protective factor [Santin 2011].

Insect repellent activity
Tick nymphs (*Ixodes ricinus*) were exposed to clove oil on filter paper discs (0.5 mL, undiluted). Clove oil acted as a long lasting repellent (from 4h to 8h) for 68% to 78% of the nymphs, compared to 0% repellency observed for the controls [Thorsell 2006].

Pharmacological studies in humans

Studies in humans as insect repellent
Clove oil (in 25% - 100% preparations) administered to the skin of 2 human subjects was investigated as a repellent for the prevention of bites from 2 mosquito species (*Anopheles albimanus* and *Aedes aegypti*). These applications provided protection from 1.5h up to 3.5h, in a dose-dependent manner. From a group of 15 essential oils clove oil was the only one that could selectively prevent bites of *Anopheles albimanus*. Clove oil, in the dilution range of 25% - 100%, was 7 times more effective compared to a synthetic repellent (25% Deet, N,N-diethyl-3-methylbenzamide) [Barnard 1999].

A controlled study investigating clove oil application to the skin (4 groups: 10%, 50%, undiluted oil and solvent controls) was conducted in 3 human subjects (who agreed to be test objects) for prevention of mosquito bites. The undiluted oil fully prevented bites for 2 to 4 hours in 3 mosquito species (*Aedes aegypti*, *Anopheles dirus* and *Culex quinquefasciatus*). Dose dependency was shown, 50% oil prevented bites for 1.5h [Trongtokit 2005].

Clinical studies

A randomized, single-blind, controlled, comparative clinical trial was conducted for 6 weeks. Clove oil (as a 1% cream) was applied anorectally 3 times daily, and tested against a positive control (5% lignocaine cream), in 55 patients with chronic anal fissure (clove oil n=30; lignocaine n=25). After a 3-month follow-up, significantly more of the clove oil group (60%) than the lignocaine control group (12%) were symptom-free ($p<0.001$). Significant decreases in anal sphincter pressures were also reported for the clove oil patients. The majority of clove oil patients did not require additional systemic analgesics during the study, presumably because of the anaesthetic effect of 1% clove oil. This demonstrated a further advantage when compared to the control group who had received the traditional treatment of stool softeners and the topical anaesthetic 5% lignocaine cream [Elwakeel 2007].

Pharmacokinetic properties

Pharmacokinetics in animals

Absorption, metabolism, elimination
Pharmacokinetics of orally administered eugenol were assessed in rats following administration by gavage of 40 mg/kg for 5 successive days. Blood samples were collected over 24h. Eugenol in blood peaked rapidly, but mean $T_{1/2}$ values of eugenol in plasma and blood were quite long, at 14.0 h and 18.3 h respectively, suggesting a potential accumulation following repeated administration [Guenette 2007].

Eugenol is rapidly metabolized and excreted. Over 70% of an oral dose was excreted in the urine of rabbits. Eugenol had little or no effect on microsomal enzyme induction [Opdyke 1975b].

Blood and urinary samples from rats given a single intravenous dose of 20 mg/kg eugenol were collected over 1h for pharmacokinetic assessment. Mean systemic clearance from plasma and blood was 157 and 204 ml/min/kg respectively. Glucuronide and sulphate conjugate metabolites were identified in urine [Guenette 2006].

Pharmacokinetics in humans

Absorption, metabolism, elimination
Eugenol was rapidly absorbed and metabolized after oral administration to male and female healthy volunteers with 95% of the dose recovered in the urine within 24h. Most were phenolic conjugates (99%), plus nine metabolites of eugenol [Fischer 1990].

Dental healthcare/ anaesthetic
In vivo drug release studies were conducted with 6 healthy human volunteers using a eugenol-containing mucoadhesive layer (200 mg tablet contained 10 mg eugenol) stuck to the gums. The tablets remained on the gums up to 8h. Eugenol was completely released at 6h in 1 of 3 tested formulations [Jadhav 2004].

Preclinical safety data for clove oil and eugenol

Clove oil

Acute toxicity
In rats, the acute oral LD_{50} value of clove oil was 2.65-3.72 g/kg. In rabbits, the acute dermal LD_{50} was reported as 5g/kg [Opdyke 1975a].

There were no signs of toxicity, or alterations in food and water consumption, in rats during the 14 day period following a single oral dose of clove oil (2000 mg/kg b.w.).

Repeated dose and chronic toxicity studies
Rats tolerated daily oral doses of 35-70 mg clove oil well for 8 weeks. Higher doses led to inactivity and weight loss [Opdyke 1975a].

An estimated acceptable daily intake of eugenol up to 2.5 mg/kg b.w. for humans was established at the 26th and confirmed at the 65th Joint FAO/WHO Committee on Food Additives [Reynolds 1989].

Irritation of animal skin: Applied undiluted to backs of mice, clove oil was not irritating. Applied undiluted to abraded rabbit skin for 24h under occlusion it was mildly irritating [Opdyke 1975a].

Irritation of human skin: In 2 of 25 normal subjects, 20% clove oil in vaseline caused erythema in a closed-patch test on the skin. In 30 normal subjects tested at 2%, and in 35 subjects with dermatoses tested at 0.2%, no reaction was evoked. Tested at 5% in vaseline it produced no irritation after a 48h closed-patch test in humans [Opdyke 1975a].

Sensitization (human test): In a maximization test, clove oil at 5% in vaseline produced no sensitization reactions in 25 volunteers. In another study sensitization caused by clove oil was attributed to eugenol [Opdyke 1975a].

Human dental pulp: A zinc oxide-clove oil paste damaged the dental pulp in human dental cavities [Opdyke 1975a].

Mutagenicity and carcinogenicity
Clove oil was cytotoxic for HEP-2 cells (human carcinoma-derived) at ID_{50} = 7.31 µg/ml [Saenz 1996]. Clove oil and eugenol were both found to be cytotoxic to human fibroblasts and to a human transformed dermal endothelial cell line at concentrations as low as 0.03%V/V and 0.06%V/V, respectively. β-caryophyllene was not cytotoxic to these cells [Prashar 2006].

Reproductive toxicity
Motility and viability of human spermatozoa were investigated *in vitro*. Clove oil tested for immediate spermicidal activity was minimally effective at a concentration of 0.5 % V/V. Eugenol had a similar minimal effect at 0.33 %V/V [Buch 1988]. Female mating mice on a diet with additional 0.25% clove oil for 2 weeks, exhibited a slight but significant increase in embryo cell death at 0.8%, compared to control mice at 0.3% ($p<.0.01$) on day 4 of pregnancy [Domaracky, 2007].

Eugenol

Acute toxicity
Oral LD_{50} of eugenol in rats was 2.68 g/kg; in mice 3.00 g/kg; in guinea pigs 2.13 g/kg. Minor liver damage occurred in rats given oral doses of 900 mg/kg 4 times daily. The highest *no effect oral dose* in dogs was 200 mg/kg b.w. [Opdyke 1975b].

There were no signs of toxicity, or alterations in food and water consumption, in rats during the 14 day period following a single oral dose of eugenol (2000 mg/kg b.w.).

Repeated dose and chronic toxicity studies
After repeated application of a 5% eugenol emulsion to the mucosa of Heidenhain's pouch (mucous membranes) in dogs, the gastric mucous barrier showed degenerative and reparative changes [Opdyke 1975b].

Short term toxicity in rats: feeding male and female rats for 19 wk (0%, 0.1% and 1% eugenol in the diet, 3 groups of 20 rats) exerted no effect on growth, haematology or organ weights and histology [Opdyke 1975b].

The effect of one drop of topically applied, undiluted eugenol, when administered to a round 3mm diameter area of rat oral/labial mucosa for 1 minute, was observed by histological procedures after periods of 15 minutes up to 6 hours. This treatment resulted in denaturation of cytoplasmic proteins, loss of staining capacity of the epithelium, loss of cell boundaries, swelling and cell necrosis. In addition, vesicle formation, edema in the corium and striated muscle dissolution were observed. It was concluded that undiluted eugenol is injurious to labial mucous membranes [Kozam 1978].

Irritation of human skin: Mild irritation was observed in a study involving 25 human subjects topically treated with 8% eugenol

in vaseline for 48 h in a closed-patch test. A patch test using undiluted eugenol for 24h produced no reaction in 20 human subjects [Opdyke 1975b].

Sensitization (human test) by eugenol was tested in 25 human volunteers: a maximization test with 8% eugenol in vaseline, applied topically, produced no sensitization reactions [Opdyke 1975b].

Mutagenicity and carcinogenicity
Carcinogen (diethyl-nitrosamine)-induced microsomal degranulation of rat liver microsomes could be protected by 3mM eugenol [Selvi 1998]. Eugenol acted as an anti-mutagen in the *Salmonella typh*. mutagen-induced SOS response test (mutagen furylfuramide and others). Eugenol suppressed 29.9% of the SOS-inducing activity at 0.60 µM/ml [Miyazawa 2001]. Eugenol at 2500 µM induced chromosomal aberrations in V79 chinese hamster cells (3.5% aberrant cells). In the presence of biotransformation mix S9, aberrations increased dose-dependently to 15%. An increase of endoreduplicated cells was observed (up to 5% at 2000 µM eugenol) [Maralhas 2006].

Cell viability
Eugenol was metabolized by isolated myeloperoxidase and inhibited the oxidative burst in phorbol-stimulated human polymorphonuclear neutrophils. Intracellular glutathione levels decreased by 90% when the cells were exposed to 100 µM eugenol [Thompson 1989]. A review discussing the clinical use of eugenol, in dental materials, suggests that prolonged exposure to concentrations of 0.001 mol/L eugenol and higher may be toxic to mammalian cells, as well as to vital dental tissue, and should be avoided [Markowitz 1992]. Rat liver mitochondria membrane potential was decreased to 50% at 7.5 µmoles/mg protein for eugenol. Mitochondrial NADH oxidase was inhibited by eugenol in a dose dependent fashion [Usta 2002].

Clinical safety data
The total number of human patients, subjects and volunteers in studies, where either clove oil or eugenol were administered by cutaneous, oromucosal or anorectal route, is 276. In these studies no adverse reactions were reported, except for mild skin irritations by 8% eugenol and erythema caused by 20% clove oil [Opdyke 1975a; Opdyke 1975b; Fischer 1990; Jadhav 2004; Barnard 1999; Trongtokit 2005 and Elwakeel 2007].

A double-dummy, controlled, randomized clinical study involving 73 human subjects was conducted in 2 groups. The clove bud group consisted of 37 healthy volunteers; clove bud powder (containing 15-20% clove oil) was administered topically and investigated for its effect as an anaesthetic on the buccal mucosa. The positive control group (36 volunteers) received a benzocaine gel (20%). Treatments were on both sides of the mouth (dummy-placebo and active agent in each subject). Adverse effects were observed only in the clove bud group; 4 of 37 clove patients developed aphthous-like ulcers at the application site of the clove bud preparation. This adverse event could not be directly attributed to the clove oil content of the clove bud powder [Alqareer 2006].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

CENTAURII HERBA

2015

Centaury

DEFINITION

Centaury consists of the whole or cut dried flowering aerial parts of *Centaurium erythraea* Rafn. s.l. including *Centaurium majus* Zeltner and *Centaurium suffruticosum* (Griseb.) Ronniger [syn. *Erythraea centaurium* Pers., *C. umbellatum* Gilib., *C. minus* Garsault].

The material complies with the European Pharmacopoeia [Centaury].

Fresh material may also be used, provided that when dried it complies with the European Pharmacopoeia.

CONSTITUENTS

The characteristic, bitter-tasting constituents are secoiridoid glucosides, principally swertiamarin (2-8%) and smaller amounts (0.1 to 0.5%) of gentiopicroside (gentiopicrin) and sweroside, with bitterness values of about 12,000 [van der Sluis 1985a, 1985b, Schimmer 1994a, Hoffmann-Bohm 2010, Aberham 2011]. Two intensely bitter *m*-hydroxybenzoyl esters of sweroside, centapicrin and deacetylcentapicrin, with bitterness values of about 4,000,000, are also present [Sakina 1976, van der Sluis 1985b, Schimmer 1994a]. Other iridoids include centauroside (a dimeric secoiridoid), secologanin, 6′-*m*-hydroxybenzoyl-loganin [Takagi 1982], dihydrocornin (a cyclopentane iridoid), gentioflavoside [Do 1987] and the secoiridoid alkaloid gentianine [Rulko 1972, Bishay 1978].

Various methoxylated xanthones [Nestha 1982, 1983, 1984, van der Sluis 1985a, 1985b, Schimmer 1994a, Valentao 2000, 2002, Hoffmann-Bohm 2010] including eustomin (1-hydroxy-3,5,6,7,8-pentamethoxyxanthone) and 8-demethyleustomin [Schimmer 1996].

Other constituents include phenolic acids, such as *p*-coumaric, *o*-hydroxyphenylacetic, ferulic, protocatechuic, sinapic, vanillic [Hatjimanoli 1977, Dombrowicz 1988, Sharaf 2003], hydroxyterephthalic and 2,5-dihydroxyterephthalic acids [Hatjimanoli 1988]; flavonoids [Sharaf 2003]; phytosterols (β-sitosterol, stigmasterol, campesterol and others) [Popov 1969, Aquino 1985, Loizzo 2008]; 5-formyl-2,3-dihydroisocoumarin [Valentao 2003a]; amino acids [Petlevski 2002]; small amounts of essential oil (up to 0.02%) [Jovanović 2009, Jerković 2012] and triterpenoids [Bellavita 1974, Loizzo 2008, Jäger 2009].

CLINICAL PARTICULARS

Therapeutic indications

Dyspeptic complaints; lack of appetite [Centaurium 1983, Bisset 1994, Leung 1996, Newall 1996, Hoffmann-Bohm 2010].

Posology and method of administration

Dosage

Adults: 1-4 g of the drug as a maceration, infusion or decoction in 150 mL of water, up to 3 times daily [Centaurium 1983, Bisset 1994, Leung 1996, Newall 1996, Hoffmann-Bohm 2010]; 2-4 mL of liquid extract (1:1, ethanol 25 % V/V), up to 3 times daily [Centaurium 1983, Newall 1996, Hoffmann-Bohm 2010]; tincture (1:5, ethanol 70 % V/V), 2-5 g daily [Hoffmann-Bohm 2010].

Children: proportion of adult dose according to age or body weight, in ethanol-free dosage forms.

The dosage may be adjusted according to the bitterness sensitivity of the individual.

E/S/C/O/P MONOGRAPHS

Method of administration
For oral administration in liquid preparations. For lack of appetite, administered half to one hour before meals [Hoffmann-Bohm 2010]; for dyspepsia, taken after meals.

Duration of administration
No restriction. If symptoms persist, medical advice should be sought.

Contra-indications
As with other drugs containing bitter substances, peptic ulcers are a contra-indication for centaury [Hoffmann-Bohm 2010].

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antioxidant and radical scavenging activities
A lyophilized hot water extract of centaury (7.5:1) exhibited antioxidant activity as shown by scavenging of superoxide radical in the NADH/PMS system (IC_{50} 120.2 µg/mL) as well as xanthine oxidase inhibitory activity (IC_{50} 73.2 µg/mL) [Valentao 2001].

In the hydroxyl radical assay a lyophilized infusion (1:100; yield 13.4%) showed an IC_{50} of 44.4 µg/mL [Valentao 2003b].

An infusion of powdered centaury (1:110; 100 µL) led to a 73.3% inhibition of desoxyribose decomposition [Gião 2008].

Methanolic extracts demonstrated moderate to low radical scavenging and antioxidant activities in various assays [Šiler 2014, Tusevski 2014].

Antimicrobial activity
In a panel of 17 bacteria gentiopicroside was most active against *Serratia marescens* with a MIC of 6.3 µg/mL [Kumarasamy 2003a]. In a similar study on 14 different bacteria swertiamarin showed the highest activity against *Citrobacter freundii* (MIC 5 µg/mL) [Kumarasamy 2003b].

Other effects
A chloroform extract containing mainly terpenes and fatty acids moderately inhibited α-amylase and α-glucosidase with IC_{50} values of 64.9 and 74.9 µg/mL respectively. The effect against angiotensin converting enzyme was weak [Loizzo 2008].

In vivo experiments

Anti-inflammatory activity
In the air pouch granuloma test in rats a dry aqueous extract of centaury (3.8:1), applied topically as 5% and 10% creams, exhibited significant transdermal anti-inflammatory activity compared to placebo ($p<0.01$). The anti-inflammatory activity of the extract was also demonstrated in Freund's adjuvant-induced polyarthritis, in rats treated orally with doses of 10-500 mg per day ($p<0.01$) [Berkan 1991].

A dry ethanolic extract, administered orally to rats at 100 mg/kg b.w., inhibited carrageenan-induced paw oedema by 40 % compared to control ($p<0.01$) [Capasso 1983].

Gastroprotective effects
Male Sprague-Dawley rats were treated intragastrically with a 50% ethanolic extract at 100 mg/kg b.w. for 7 days and additionally on day 7 with 200 mg/kg acetylsalicylic acid (ASA) 4 hours before sacrifice. Controls received saline during the same period and 200 mg/kg ASA on day 7. The extract led to a 77% inhibition of gastric lesions ($p<0.05$). The increase in catalase and malondialdehyde and the decrease in reduced glutathione caused by ASA were improved by the extract. The augmentation of myeloperoxidase activity, as an index of neutrophil infiltration into gastric mucosal tissue due to ASA, was significantly reduced ($p<0.05$) as compared to control [Tuluce 2011].

Effects on hyperglycaemia and lipid profiles
Male C57BL/6J mice received a high fat diet to induce type-2 diabetes. Simultaneous intragastric treatment with a dry extract (80% ethanol, yield 17.3 %) at a dose of 2 g/kg b.w. daily for 20 weeks resulted in a significant reduction of the mean fasting blood glucose level ($p<0.05$) from week 14 until week 20 as compared to untreated animals on the high fat diet. At the end of the experiment, plasma insulin concentrations, insulin resistance calculated by the homeostasis model assessment and plasma triglyceride levels were also significantly lower ($p<0.05$). No significant differences were observed between the treated group on high fat diet and controls on standard diet [Hamza 2010].

In a similar experiment type-2 diabetes was first established by 17 weeks of high fat diet. After this period treatment was started with the extract (80% ethanol, yield 17.3 %) at 2 g/kg b.w. daily for 18 weeks. At the end of the study body weight, mean fasting blood glucose level, plasma insulin concentration and insulin resistance were significantly better ($p<0.05$) as compared to untreated animals on the high fat diet. Administration of the extract also improved hypertriglyceridaemia and hypercholesterolaemia ($p<0.05$) without influencing HDL-cholesterol [Hamza 2011].

In streptozotocin (STZ)-induced diabetic male Wistar rats, treatment with 200 mg/kg b.w. of a lyophilized aqueous extract (1:10; yield 12%) for 30 days resulted in a significant reduction of serum glucose ($p<0.001$) and increase of serum insulin levels ($p<0.01$). Elevated triglycerides and total cholesterol in the diabetic rats were decreased significantly ($p<0.001$) by the extract. Markers of oxidative stress such as pancreatic malondialdehyde, protein carbonyl content and GSH as well as the decline in antioxidant enzymes in the pancreas (SOD, catalase, GSH peroxidase) due to the induced diabetes were improved significantly ($p<0.001$ to $p<0.01$) by the extract. Histological examination of the pancreas revealed a significant ($p<0.01$) increase in number and diameter of islets in the extract group as compared to the untreated diabetic group [Sefi 2011].

The effects of centaury on blood glucose levels, hepatic glycolytic

and gluconeogenic enzymes and their substrates, as well as on the lipid profile, were studied in male Wistar rats. Ten days after induction of diabetes with STZ the animals were treated intragastrically with a methanolic dry extract (yield 23.1%) for 12 days with 125, 250 or 500 mg/kg b.w. per day (short term treatment s.t.t.) or for 45 days with 250 mg/kg b.w. per day (long term treatment l.t.t.). Glibenclamide (2.5 mg/kg b.w. intragastrically) served as positive control. During s.t.t. blood glucose concentrations were significantly ($p<0.05$) reduced by all doses as compared to the start of the treatment. In l.t.t. the positive effect on blood glucose regulation was most pronounced up to day 30. The extract and glibenclamide normalised the diabetes-induced increases in liver glucose concentration, glucose-6-phosphatase and fructose-1,6-biphosphatase activity, as well as the decreases in liver glycogen content and glycogen phosphorylase activity. Increased triglycerides, LDL, HDL and cholesterol levels in diabetic rats were restored to the levels of untreated normal rats by all doses of the extract in s.t.t. [Stefkov 2014].

Hepatoprotective effects
A dried methanolic extract (6.2:1) was tested for its hepatoprotective effects in male Wistar rats receiving the extract intragastrically at a dose of 300 mg/kg b.w. for 6 days or at a single dose of 900 mg/kg before challenge with paracetamol. The strong increase in SGPT, SGOT and LDH levels induced by the acute administration of paracetamol was markedly attenuated by both pretreatments. The extract alone (300 mg/kg b.w. for 6 days; no paracetamol challenge) slightly reduced LDH but did not change SGPT and SGOT as compared to the untreated control. Histopathological examination of the livers confirmed the hepatoprotective effects of the extract [Mroueh 2004].

Isolated gentiopicroside significantly inhibited the production of TNF in carbon tetrachloride-induced and bacillus Calmette-Guérin/lipopolysaccharide-induced models of hepatic injury in mice after i.p. injection at 30 mg/kg ($p<0.05$) or 60 mg/kg b.w. ($p<0.01$) daily for 5 days [Kondo 1994].

Other effects
The antipyretic activity of a dry aqueous extract of centaury (3.8:1) was demonstrated in rats after intragastric administration of 50-100 mg in a yeast-induced fever test ($p<0.05$) [Berkan 1991].

A diuretic effect was shown in rats after oral administration of 8% or 16% aqueous extract of centaury at 10 mL/kg b.w. daily for one week. From the fifth day of treatment urine volume was increased significantly ($p<0.05$) with the lower dose, and both doses led to a significant increase of sodium, chloride and potassium excretion ($p<0.01$ – $p<0.001$). At the end of the treatment a diminution in creatinine clearance was observed ($p<0.05$ for the lower dose) [Haloui 2000].

Pretreatment of rats with a 50% ethanolic extract at an intragastric dose of 100 mg/kg b.w. for 7 days significantly ($p<0.05$) improved the increases in ALAT, ASAT, creatinine and potassium induced by administration of 200 mg/kg of ASA on day 7 [Ozkol 2011].

Larvae of red flour beetles (*Tribolium castaneum*) on a diet containing 10% of a methanolic extract gained significantly ($p<0.05$) less weight over 8 days than untreated control and starved larvae. Larval mortality was 62% after ten days and emergence of adult insects reduced to 33.7% as compared to 0% and 100%, respectively, in untreated control. Treated larvae had a significantly reduced α-amylase activity ($p<0.05$). Progeny production of F1 adults was completely suppressed by the extract [Jbilou 2008].

Isolated swertiamarin showed anticholinergic activity, significantly inhibiting carbachol-induced contractions of the proximal colon in rats in a dose-dependent manner ($p<0.05$) after oral administration at 150 mg/kg and 300 mg/kg b.w. [Yamahara 1991].

Clinical studies
No published clinical data currently available.

Pharmacokinetic properties
By anaerobic incubation with a mixture, and with individual strains, of human intestinal bacteria, swertiamarin was converted to three metabolites: erythrocentaurin, 5-hydroxymethylisochroman-1-one and gentianine. This demonstrated that orally administered swertiamarin can be transformed into a nitrogen-containing, biologically active substance by flora of the human gastrointestinal tract [El-Sedawy 1989].

Preclinical safety data

Acute toxicity
A dried aqueous decoction (1:10; yield not specified) administered orally at doses of 1 to 15 g/kg b.w. to male and female mice did not cause any signs of toxicity at any dose level. After i.p. administration at doses of 2 to 14 g/kg b.w. adverse effects such as anorexia, piloerection and hypoactivity were observed at higher doses from 8 g upwards; asthenia, diarrhoea and convulsions occurred in both sexes at doses above 12 g/kg b.w. The i.p. LD_{50} was calculated as 12.13 g/kg [Tahraoui 2010].

Isolated iridoids were shown to be toxic in the brine shrimp lethality assay (LC_{50} values: gentiopicroside 24 µg/mL, swertiamarin 8.0 µg/mL, sweroside 34 µg/mL, podophyllotoxin as control 2.7 µg/mL) [Kumarasamy 2003a,b].

Repeated dose and chronic toxicity studies
A dried aqueous decoction (1:10; yield not specified) was administered orally to male and female Wistar albino rats at 100, 600 and 1200 mg/kg b.w. daily for 90 days. No lethality or significant differences in body weight changes or in animal behaviour were noted in any of the groups. Blood cell counts were unaffected and haematological parameters remained within normal limits throughout treatment. The only change was a slight but significant decrease in mean red blood cell volume (600 mg/kg: $p<0.05$ after 30 days and $p<0.01$ after 60 and 90 days; 1200 mg/kg: $p<0.05$ after 90 days; compared to control). In the biochemical profiles plasma creatinine, urea, total proteins, total bilirubin, cholesterol, ALAT and ASAT remained unchanged. Blood glucose and triglycerides were significantly reduced ($p<0.05$) at doses of 600 and 1200 mg/kg from 60 days until the end of treatment [Tahraoui 2010].

Mutagenicity and carcinogenicity
Centaury extracts have been evaluated in the Ames mutagenicity test using *Salmonella typhimurium* strains TA98 and TA100 (with and without activation by S9 mix), with rather conflicting results. An inspissated extract showed weak mutagenicity in TA98, but negative results were obtained with a fluid extract and a tincture in strains TA98 and TA100 [Schimmer 1994b]. In another study, a fluid extract and a tincture showed weak mutagenicity in strain TA100, but not in strain TA98 [Göggelmann 1986].

An ethanolic extract of centaury at 200 µL/plate displayed markedly antimutagenic potency in *Salmonella typhimurium* strains TA98 and TA100, inhibiting mutagenicity induced by 2-nitrofluorene (2-NF) and 2-aminoanthracene (2-AA) by over 50 %. Furthermore, isolated eustomin at 50 µg/plate showed strong inhibition, 76 % against 2-NF and 64 % against 2-AA in strain TA100; 8-demethyleustomin was also active, with results of 43 % and 39 % respectively, but no inhibition was detected from secoiridoid or polar fractions of centaury [Schimmer 1996].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

CHAMOMILLAE ROMANAE FLOS 2019

Roman Chamomile Flower

DEFINITION

Roman chamomile flower consists of the dried flower-heads of the cultivated double flowered variety of *Chamaemelum nobile* (L.) All. (syn. *Anthemis nobilis* L.). It contains not less than 7 mL/kg of essential oil.

The material complies with the monograph of the European Pharmacopoeia [Chamomile Flower, Roman].

CONSTITUENTS

The main characteristic constituents are the essential oil (0.6-2.4%) [Zwaving 1982], flavonoids [Herisset 1971, 1973, 1974] and derivatives such as apigeninglycosides [Chao-Mei 2007; Tschan 1996], acidic polysaccharides (3.9%) [Lukacs 1990], catechins [Herisset 1970], coumarins [Zwaving 1982], hydroperoxides such as 1-β-hydroperoxyisonobilin and allylhydroperoxides [Rücker 1989; Mayer 1987], octulosonic acid derivatives [Zhao 2014], β-amyrin and sterols such as taraxasterol, pseudotaraxasterol and β-sitosterol [Power 1914; Zyczyńska-Baloniak 1971; Fauconnier 1996].

The essential oil contains approximately 75%-85% aliphatic esters of angelic, tiglic, isovaleric and isobutyric acids, where angelates represent approximately 65% of the oil with isobutyl angelate (25%-32%) predominating [Omidbaigi 2003, 2004]. The main flavonoid glycoside (1.5-2.4%) is chamaemeloside (apigenin 7-glucoside-6''-(3'''-hydroxy-3'''-methyl-glutarate) [Chaumont 1969; Tschan 1996; Chao-Mei 2007] among other phenolic compounds [Avula 2013].

Other constituents include cerotic, stearic, palmitic, oleic and linoleic acids [Power 1914; Duarte 2005; Bail 2009; Guimarães 2013]. Monoterpenes (estragol, α-pinene) and sesquiterpenes of the germacranolide type including nobilin [Benešová 1964, 1970], 3-epinobilin, 1,10-epoxynobilin, 3-dehydronobilin and hydroxyisonobilin [Holub 1977; Tognolini 2006]. Spiroethers and the coumarin herniarin have also been identified [Wichtl 2009; Chao-Mei 2007].

CLINICAL PARTICULARS

Therapeutic indications

Internal use
Symptomatic treatment of mild dyspeptic complaints, such as bloating, nausea, flatulence and lack of appetite [Ellingwood 1919; Felter 1922; Rápóti 1974; Lukacs 1990; Bradley 1992; Rivera 1995; Duarte 2005; Wichtl 2009].

External use
For minor inflammations of the oral mucosa and skin in wounds and abrasions; as an itch-relieving agent [Bradley 1992; Bruneton 1999; Wichtl 2009]; for eye irritation or discomfort [Rivera 1995].

These indications are plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Internal use
Adult daily dose
Preparations equivalent to 1.5-12 g of the drug [Ellingwood 1919; Bradley 1992; Wichtl 2009].
Liquid extract (DER 1:1 in 70% alcohol): 1–4 mL three times daily [Barnes 2007].

Not recommended for children below 12 years.

External use
Topical use as a 3% infusion [Wichtl 2009] in poultices or mouthwashes, or as semi-solid preparations containing 5-15% of the drug or equivalent [Bradley 1992]. As a bath additive, 50 g are added to 10 litres of water; 'liquid rubs' are applied as poultices or washes 2 to 3 times daily [Gruenwald 2004].

Method of administration
Oral administration; oromucosal and topical applications.

Duration of use

Internal use
No restriction.

External use in poultices or mouthwashes
No restriction.

If symptoms persist or worsen, medical advice should be sought.

Contraindications
Persons with known sensitivity to plants of the Asteraceae family [Blumenthal 1998; Brinker 2001, 2008]. Nobilin and its derivatives are reported as the probable contact allergens of Roman chamomile [Benner 1973; McGeorge 1991; Bossuyt 1994; Hausen 1997; Pereira 1997; Giordano-Labadie 2000; Maddocks-Jennings 2004].

Special warnings and special precautions for use
None required.

Interaction with other medicinal products and other forms of interaction
As a precaution, Roman chamomile should not be used concomitantly with aspirin, warfarin or other substances possessing anticoagulant activitiy [Bratman 2003; Heck 2000].

Since apigenin is a ligand for the central benzodiazepine receptor, Roman chamomile should not be used concurrently with diazepam or other benzodiazepines, as this may potentiate their action [Paladini 1999; Viola 1995].

Some constituents may inhibit cytochrome P450 3A4 enzymes [Budzinski 2000]. Roman chamomile essential oil exhibited ≤40% inhibition of CYP3A4 activity [Cochrane 2015].

Pregnancy and lactation
In accordance with general medical practice it should not be taken orally during pregnancy and lactation without medical advice [Farnsworth 1975; Mills 2005].

Effects on ability to drive and use machines
None known.

Undesirable effects
None known.

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antimicrobial activities
The essential oil and various pure compounds were tested for antimicrobial activity at concentrations in the range of 1-1000 ppm. The oil and several of its constituents showed high antimicrobial activity (MIC=60 µg/mL) against *Salmonella sp.* and *E. coli*. The main constituent, isobutyl angelate, showed high activity (MIC=60 µg/mL) against *Staphylococcus aureus* and *Klebsiella pneumoniae*. The oil and most of the constituents tested also showed lower activity (MIC=600 µg/mL) against *S. aureus, Enterococcus faecali, Pseudomonas aeruginosa, Proteus vulgaris, K. pneumoniae* and the yeast *C. albicans* [Duarte 2005; Bail 2009].

The essential oil showed inhibitory activity on selected bacteria, fungi and viruses [Chao 2000], antibacterial activity against clinically isolated *Porphyromonas gingivalis* from periodontitis [Saderi 2005] and inhibition of methicillin-resistant *S. aureus* (MRSA) [Chao 2008].

A dry methanolic extract (100 mg), dissolved in 5 ml of 2% DMSO and then diluted to various concentrations in water, exhibited significant nematocidal activity when 5 mg/mL ($p<0.05$) and 10 mg/mL ($p<0.001$) were added to wells containing a 10 µl *Steinernema feltiae* nematode suspension (30-40 nematodes/well) [Al-Marby 2016].

A dichloromethane extract exhibited promising *in vitro* antiprotozoal activity against *Trypanosoma brucei rhodesiense* (IC_{50} 1.43 ± 0.50 µg/mL) and *Leishmania donovani* (IC_{50} 1.40 ± 0.07 µg/mL) [De Mieri 2017].

Antioxidant activities
Roman chamomile oil exhibited the highest antioxidant activity when compared with eleven aromatic plants typical of the Mediterranean area [Piccaglia 1993; Povilaityte 2000].

Antiplatelet activity
The essential oil exhibited a modest and dose-dependent inhibition of platelet aggregation in guinea pig platelet-rich plasma induced by three agents: ADP, arachidonic acid and a thromboxane A2 agonist. Fibrin clot retraction induced by thrombin was decreased by less than 50% by the oil at 300 µg/mL [Tognolini 2006].

Cytostatic activities
Nobilin, 1,10-epoxynobilin, 3-dehydronobilin and hydroxyisonobilin, as isolated constituents from Roman chamomile flower, showed *in vitro* cytostatic activity against human HeLa (cervix carcinoma cell line) and KB (nasopharyngeal carcinoma) cell lines. ED_{50} values for hydroxyisonobilin were 0.5 µg/mL and 1.23 µg/mL for HeLa and KB cell lines respectively [Holub 1977; Samek 1977; Grabarczyk 1977].

A study comparing the effects of a methanolic extract, a decoction and an infusion, on the growth of five human tumour cell lines (MCF-7, NCI-H460, HCT-15, HeLa and HepG2), demonstrated that the extract was more potent than the infusion in all the tested cell lines, presenting GI_{50} values (fifty percent of maximum inhibition of cell proliferation) that ranged from 82.52 to 168.40 µg/mL for the MCF-7 and HepG2 cells respectively. The decoction showed no antitumour activity at the maximum concentration (400 µg/mL) used [Guimarães 2013].

An ethyl acetate fraction obtained from Roman chamomile aerial parts demonstrated growth inhibitory activity on several cancer cell lines but had a minimal effect on normal cells. The strongest cytotoxic activity was obtained after 72 hours in MCF-7 breast cancer cells, with an IC_{50} of 0.002 mg/ml. The fraction also exhibited antiproliferative activity on breast cancer cells and induced apoptosis by activating the mitochondrial apoptotic pathway [Kandelous 2016].

Other activities
A hydroethanolic extract, various fractions, the essential oil and 4 component flavonoids were examined for their effect on rat, guinea pig and human gastrointestinal smooth muscle preparations. The extract demonstrated a transient stimulation of smooth muscle contraction as well as a more sustained relaxing effect on precontracted smooth muscle (histamine-stimulated contraction; and pre-treated with atropine and tetrodotoxin), while the oil exhibited only the relaxing effect [Sandor 2018].

Six caffeoyl derivatives possessing a rare octulosonic acid skeleton were identified and isolated from the ethyl acetate fraction of a methanolic extract. At a concentration of 30 μM, two compounds showed an increase in LXR (liver X receptor) activity (1.59- and 1.22-fold). Another three compounds increased PPARγ activity (1.68-, 1.59- and 2.09-fold), while PPARα was activated by two of the compounds only (1.43- and 1.35-fold at 30 μM). All 6 of the compounds increased NAG-1 (NSAIDs-activated gene-1) activity by 2-3 fold at 50 μM. No cytotoxicity was observed for any of these compounds against mouse macrophages (RAW 264.7) or human hepatoma cells (HepG2) up to a concentration of 50 μM. A methanolic extract demonstrated inhibition of intracellular oxidative stress (45% inhibition of ROS generation at 200 μg/mL) and inhibition of NF-κB activity (50% inhibition at 17 μg/mL). The extract was also found to activate NAG-1 (2.2-fold at 50 μg/mL), PPARα (1.8-fold at 25 μg/mL), and PPARγ (3.0-fold at 25 μg/ mL) [Zhao 2014].

In vivo experiments

Anti-inflammatory effects
Polysaccharides isolated from an aqueous extract (10 mg/kg i.p.) reduced rat paw oedema by 36-38% compared to untreated controls. Indomethacin was used as a positive control and showed 48.6% inhibition [Lukacs 1990].

In the same model, Roman chamomile oil (350 mg/kg b.w. i.p.) reduced oedema by 23-39% after two hours and 38-43% after 3 hours. The positive control indomethacin (5 mg/kg b.w. i.p.) demonstrated 74% and 67% inhibition respectively [Melegari 1988; Rossi 1988].

Antimicrobial and wound healing activity
An ointment prepared with 5% of a dried ethanolic extract in a eucerin base gel (0.5 g/day for 2 weeks) applied to incision wounds in rats experimentally infected with *Pseudomonas aeruginosa*, eradicated the infection significantly ($p<0.05$) faster and reduced healing time compared with a tetracycline ointment and with the base gel [Kazemian 2018].

Diuretic and hypotensive effect
In spontaneously hypertensive rats a single oral dose of a dry aqueous extract (140 mg/kg b.w.) produced a significant ($p<0.05$) reduction in systolic blood pressure (SBP) after 24 h. Daily oral administration (140 mg/kg b.w.) for 3 weeks produced a significant ($p<0.01$) reduction in SBP on day 8 of treatment. The hypotensive effect was associated with a significant ($p<0.01$) increase in urinary output and excretion of electrolytes, from day 8 to the end of treatment [Zeggwagh 2009].

Hypoglycaemic effect
A single oral dose of an aqueous extract (20 mg/kg b.w.) signifcantly reduced blood glucose levels from 6.0 ± 0.3 mmol/l to 4.9 ± 0.09 mmol/l ($p<0.05$) 6 h after administration in normal rats and from 21.1 ± 1.3 mmol/l to 14.5 ± 0.9 mmol/l ($p<0.001$) in streptozotocin-induced diabetic rats. Furthermore, after daily administration of the same dose for 15 days, blood glucose levels were decreased from 6.1 ± 0.06 mmol/l to 4.6 ± 0.17 mmol/l ($p < 0.01$) and from 21.1 ± 1.31 mmol/l to 13.7 ± 0.90 mmol/l ($p<0.01$) in normal and diabetic rats respectively. Basal plasma insulin concentrations remained unchanged after treatment in both normal and diabetic rats suggesting a mechanism independent of insulin secretion [Eddouks 2005].

Psychomotor activity
Roman chamomile essential oil (though not other extracts) significantly ($p<0.05$) increased the ambulatory activity of mice in the 60 mins following an i.p. injection of 400, 1600 and 3200 mg/kg b.w. when compared to an olive oil control. Three main constituents were isolated and identified as having a significant effect, isobutyl angelate, isoamyl angelate and 2-methylbutyl isobutyrate. However, a combination of these three constituents did not fully reproduce the activity of the essential oil suggesting other constituents also play a role in the ambulatory effect. Dopamine antagonists (chlorpromazine and haloperidol) attenuated the effects of the isolated constituents [Umezu 2017].

Clinical studies
In a randomised, double-blind, placebo-controlled study involving 55 patients with oral lichen planus, the effect of a gel containing 2% chamomile (chamomile preparation not futher defined; n=26) was compared to a placebo base gel (n=29), when applied topically to the affected areas of the oral cavity at 0.5 ml three times per day for 4 weeks. In the chamomile group, 92% of patients showed some improvement with 5 patients showing a complete resolution, while in the placebo group only 19.2% showed a response to treatment and none showed complete resolution. The chamomile group also exhibited significant improvements compared to baseline in pain ($p<0.001$), burning sensation ($p<0.001$), itching ($p=0.011$), Thongprasom Index ($p=0.001$) and Oral Health Impact Profile 14 ($p<0.001$); while there were no significant changes found in the placebo group [Lopez Jornet 2016].

Pharmacokinetic properties
No data available.

Preclinical safety data

Single dose toxicity
The acute oral LD_{50} of Roman chamomile flower oil was more than 5 g/kg b.w. in rats. Applied to the backs of hairless mice it produced no irritating effects. On intact or abraded rabbit skin for 24 hours under occlusion, the oil was only mildly irritating and lacked phototoxic effects [Opdyke 1974].

Genotoxicity and mutagenicity
Roman chamomile oil possessed *in vitro* genotoxic properties in the *Bacillus subtilis* rec-assay and Salmonella/microsome reversion assay [Zani 1991].

Clinical safety data

Reproductive and developmental toxicity
After case-control analysis of 424 women with low weight newborns (< 2500 g), no statistically significant associations were found between the use of Roman chamomile tea during the last 2 trimesters of pregnancy, either alone or in combination with other herbal products, and the risk of low birth weight [Moussally 2012].

Allergic reactions
Two cases of contact dermatitis of the nipple were reported in breast-feeding women after using a Roman chamomile containing ointment [McGeorge 1991].

Sensitization to Roman chamomile (dried flowers, oil) has been reported [Benner 1973; Hausen 1997], and has been discussed in relation to compresses containing Roman chamomile in patients with a known positive allergic reaction to a sesquiterpene lactone mix [Bossuyt 1994; Pereira 1997; Giordano-Labadie 2000].

An idiosyncratic allergic reaction (head rush, tachycardia and nausea) was reported after inhaling Roman chamomile oil that had been dropped on to a strip in an aromatherapy class exercise [Maddocks-Jennings 2004].

A study evaluating which constituents of two commercial Compositae mixes would be the most useful as screening agents involved 76 patients testing positive to Compositae mix 6% in petrolatum and 29 patients testing positive to Compositae mix in 5% petrolatum. All patients were tested with the constituents of the respective mixes, but none were found to be positive to Roman chamomile [Paulsen 2012].

A safety assessment review of various Roman chamomile preparations (flower extract, oil, powder and water) used in cosmetics at a concentration of up to 10% (flower water) concluded these ingredients are safe at these concentrations, when used in non-sensitizing formulations [Johnson 2017].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin

i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection

CIMICIFUGAE RHIZOMA 2011

Black Cohosh

DEFINITION

Black cohosh consists of the dried rhizomes and roots of *Actaea racemosa* L. [*Cimicifuga racemosa* (L.) Nutt.] harvested in summer or autumn.

To comply with the monograph of the United States Pharmacopeia [Black Cohosh USP] the material should contain not less that 0.4 per cent of triterpene glycosides, expressed as 23-*epi*-26-deoxyactein ($C_{37}H_{56}O_{10}$; M_r 660.8) and calculated with reference to the dried drug.

A draft monograph intended for inclusion in the European Pharmacopoeia has been published [Black Cohosh]; it requires not less that 1.0 per cent of triterpene glycosides, expressed as monoammonium glycyrrhizate ($C_{42}H_{65}NO_{16}$; M_r 840) and calculated with reference to the dried drug.

CONSTITUENTS

Triterpene glycosides with a highly oxidized cycloartane-type skeleton, glycosylated at the C-3 position. Acetylacteol, cimigenol and shengmanol represent the major aglycones, and arabinose and xylose the dominant sugar moieties [Bedir 2000, Bedir 2001, Chen 2002a, Chen 2002b, Chen 2007, He 2000, He 2006, Li 2006, Mimaki 2006, Nuntanakorn 2006, Shao 2000, Watanabe 2002, Wende 2001].

The major glycosides have been identified as actein [Chen 2002b, Ganzera 2000, He 2000, He 2006, Li 2002], cimicifugoside[1] [He 2000, He 2006, Piancatelli 1971, Shao 2000], cimiracemoside A[2] [Bedir 2000, Ganzera 2000, He 2006] and 23-*epi*-26-deoxyactein [Chen 2002b, He 2006], formerly known as 27-deoxyactein [Berger 1988, He 2000, Shao 2000]. Cimigenol-3-*O*-α-L-arabinoside has been proposed as a species-specific marker glycoside for *C. racemosa* [He 2006]. A chlorine-containing triterpene glycoside might be an artefact [Chen 2007].

Phenylpropanoids (min. 0.5% expressed as caffeic acid), principally derivatives of hydroxycinnamic acids:

- Caffeic, ferulic and isoferulic acids [He 2006, Kruse 1999].
- Hydroxycinnamic acid esters of fukiic acid, e.g. fukinolic acid, cimicifugic acid A, cimicifugic acid B and cimicifugic acid G [He 2006, Kruse 1999, Nuntanakorn 2006].
- Hydroxycinnamic acid esters of piscidic acid, e.g. cimicifugic acid D, cimicifugic acid E and cimicifugic acid F [He 2006, Kruse 1999, Stromeier 2005].
- Other phenylpropanoid esters such as methyl caffeate [Chen 2002c], caffeoylglycolic acid, cimiciphenol, cimiciphenone [Stromeier 2005], petasiphenone [Jarry 2007, Stromeier 2005] and cimiracemates A-D (phenylpropanoid ester dimers) [Chen 2002c].

Other constituents include a cyclic guanidine alkaloid, cimipronidine (also proposed as a potential marker for *C. racemosa*) [Fabricant 2005], N_ω-methylserotonin [Powell 2008], starch, fatty acids, resin and tannins [Beuscher 1995].

[1] Cimicifugoside (cimigenol 3-O-β-D-xyloside) as isolated by He et al. [He 2000], Shao et al. [Shao 2000] and earlier by Piancatelli and coworkers [Piancatelli 1971] from *Cimicifuga racemosa*; in some literature it is called cimigoside or cimifugoside. A different 'cimicifugoside' has been isolated from the rhizoma of *Cimicifuga simplex* by Kusano et al. [Kusano 1998]; it is the 3-*O*-xyloside of an aglycone with a cyclolanost-7-ene structure.

[2] Cimiracemoside A (cyclolanost-7-ene 3-*O*-β-D-xyloside) as isolated by Bedir and Khan [Bedir 2000] and mentioned later by Ganzera et al. [Ganzera 2000] and He et al. [He 2006]. At almost the same time a different 'cimiracemoside A', identified as 21-hydroxycimigenol-3-*O*-α-arabinoside, was isolated from black cohosh by Shao et al. [Shao 2000].

CLINICAL PARTICULARS

Therapeutic indications
Climacteric symptoms such as hot flushes, profuse sweating, sleep disorders and nervous irritability [Osmers 2005, Bai 2007, Nappi 2005, Wuttke 2003b, Hernández Muñoz 2003, Kaiser 2008, Frei-Kleiner 2005, Oktem 2007].

Posology and method of administration

Dosage

Adult daily dose
Isopropanolic (40%V/V) [Osmers 2005, Bai 2007, Nappi 2005, Lehmann-Willenbrock 1988] or ethanolic (40-60%V/V) [Wuttke 2003b, Hernández Muñoz 2003, Kaiser 2008, Frei-Kleiner 2005] extracts corresponding to 40-140 mg of black cohosh; other corresponding preparations.

Method of administration
For oral administration.

Duration of administration
No restriction.

In efficacy studies patients have been treated with black cohosh extracts for periods of 3 months [Osmers 2005, Bai 2007, Nappi 2005, Wuttke 2003b, Kaiser 2008, Juliá-Mollá 2009], 6 months [Briese 2007, Fischer 2006, Liske 2002, Lehman-Willenbrock 1988, Pethö 1987] or 12 months [Geller 2009, Briese 2007, Raus 2006, Hernandez-Muñoz 2003].

In placebo-controlled studies with treatment periods of 3-12 months no significant differences in adverse effects were evident between black cohosh groups and placebo groups [Shams 2010, Geller 2009, Kaiser 2008, Reed 2008, Osmers 2005, Wuttke 2003b].

Contra-indications
Hypersensitivity to black cohosh.

Special warnings and special precautions for use
The use of black cohosh in patients with pre-existing breast cancer should be approached with caution. The evidence from pharmacological studies, *in vitro*[3] and *in vivo*[4], suggests that black cohosh extracts do not influence the latency or development of breast cancer and may have inhibitory effects[5]. However, contradictory results have been obtained in isolated *in vitro* experiments [Liu ZP 2001]. Clinical experience suggests a lack of risk [Wuttke 2003b, Low Dog 2003, Borrelli 2008b, Obi 2009].

A doctor should be consulted in the event of menstrual disorders or the reappearance of menstruation and if symptoms persist or new symptoms appear.

Black cohosh should only be used with caution in patients with pre-existing liver disease. Patients should stop taking black cohosh immediately if signs and symptoms occur suggesting a liver injury (icterus, dark urine, upper stomach pain, nausea, loss of appetite, tiredness) [EMEA 2007, Mahady 2008].

Interactions with other medicaments and other forms of interaction
None known.

Ethanolic (75% and 80%) extracts and a 40%-isopropanolic extract from black cohosh concentration-dependently inhibited the activity of four CYP450 enzymes (1A2, 2D6, 2C9 and 3A4) *in vitro* with IC_{50} values ranging from 21.9 to 65.0 µg/ml. Isolated triterpene glycosides were found to be weakly active (IC_{50}: 25-100 µM), while fukinolic acid and cimicifugic acids A and B were somewhat more active (IC_{50}: 1.8-12.6 µM) [Huang 2010].

Pregnancy and lactation
Black cohosh should not be used during pregnancy and lactation [Lepik 1997, Dugoua 2006, Barnes 2007].

Effects on ability to drive and use machines
None known.

Undesirable effects
In rare[6] cases gastrointestinal disorders (dyspepsia, diarrhoea), allergic skin reactions (urticaria, pruritus, skin rash) or facial and peripheral oedema. Rarely[6], an increase in liver enzymes (transaminases) may occur.

Liver injury associated with the use of black cohosh preparations has been reported with a very rare[6] frequency, but a causal relationship has not been proven to date [Lieberman 1998, Liske 1998, EMEA 2007, Hudson 2007, Borrelli 2008b, Firenzuoli 2008, Mahady 2008, Mazzanti 2008, Teschke 2009a, Teschke 2009b, Teschke 2010].

Overdose
Nothing of relevance reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Influence on breast cancer cells
The majority of studies evaluating the effects of black cohosh extracts on human oestrogen receptor-positive (ER^+) and -negative (ER^-) breast cancer cell lines have demonstrated inhibition of proliferation, or at least a lack of proliferative effects:

- An isopropanolic extract from black cohosh significantly inhibited proliferation of the oestrogen receptor-positive human breast cancer cell line 435 at concentrations of 2.5-25 µg/ml [Nesselhut 1993].

[5] [Nesselhut 1993, Dixon-Shanies 1999, Bodinet 2002, Zierau 2002, Bodinet 2004, Einbond 2004, Hostanska 2004a, Hostanska 2004b, Einbond 2006, Garita-Hernandez 2006, Al-Akoum 2007, Einbond 2007a, Einbond 2007b, Gaube 2007, Hostanska 2007, Rice 2007, Stute 2007, Einbond 2008, Omer-Adam 2008]

[6] The stated frequency of the specified adverse reactions is the incidence rate in patients exposed to black cohosh preparations within appropriate limits of dosage and treatment duration, defined in accordance with a convention adopted by the European Commission: very common (≥1/10); common (≥1/100 to <1/10); uncommon (≥1/1,000 to <1/100); rare (≥1/10,000 to <1/1,000); very rare (<1/10,000) [European Commission].

- A 40%-isopropanolic extract from black cohosh at dilutions corresponding to native dry extract at 1-100 µg/ml significantly and dose-dependently inhibited proliferation of the oestrogen receptor-positive human breast adenocarcinoma cell line MCF-7 under oestrogen-deprived conditions ($p<0.05$) and also inhibited oestrogen-induced proliferation of the cells ($p<0.05$ vs. oestradiol 10^{-8} M control). Furthermore, the proliferation-inhibiting effect of tamoxifen at 10^{-6} M was enhanced by the extract. The results suggested a non-oestrogenic or oestrogen-antagonistic effect of the black cohosh extract [Bodinet 2002].

- Neither of two black cohosh extracts (one ethanolic, the other isopropanolic) exhibited oestrogenic activity in proliferation assays of oestrogen receptor-positive MCF-7 cells; the extracts antagonized oestradiol-induced stimulation of proliferation of the cells at concentrations > 1 µg/ml [Zierau 2002].

- A 50%-ethanolic extract of black cohosh (2 g/10 ml) at a concentration of 2 µl/ml did not stimulate proliferation of oestrogen receptor-positive T47D human breast cancer cells, assessed by measuring the increase/decrease in total protein in cell cultures for 9 days [Zava 1998].

- A similar 50%-ethanolic extract significantly inhibited the growth of oestrogen receptor-positive T47D human breast cancer cells at concentrations of 0.1 and 1% V/V [Dixon-Shanies 1999].

- In S30 breast cancer cells the oestrogen-inducible gene presenelin-2 was not up-regulated in the presence of a methanolic extract from black cohosh [Liu J 2001].

- The growth of oestrogen-dependent human breast cancer MCF-7 cells was not stimulated by 48-hour treatment with an alcoholic extract from black cohosh (extraction solvent not further defined) at dilutions from 1:500 to 1:5000. In contrast, in the same test, growth of MCF-7 cells was induced concentration-dependently by dong quai (*Angelica sinensis*; 27-fold at 1:500 dilution, $p<0.001$) and ginseng (16-fold at 1:500 dilution, $p<0.05$); however, since these herbal drugs did not show any oestrogenic activity as measured in a transient gene expression assay and an *in vivo* bioassay in mice, the authors considered the effect on MCF-7 cells to be independent of oestrogenic activity [Amato 2002].

- Black cohosh (extraction solvent not further defined) at concentrations from 0.1 to 100 times the maximum possible serum concentration of the herb did not stimulate the proliferation of oestrogen-sensitive (T-47D) or -insensitive (HCC-1937) breast cancer cells [Morris 2003].

- A 40%-isopropanolic extract not only failed to increase the proliferation of MCF-7 cells under oestrogen-deprived conditions in an MCF-7 test culture system but significantly inhibited proliferation ($p<0.001$) at dilutions corresponding to black cohosh root at 0.04-40 µg/ml. In the presence of oestradiol (10^{-7} M) the extract inhibited oestrogen-induced proliferation and showed oestrogen-antagonistic activity [Bodinet 2004].

- Three different black cohosh extracts (a 50%-ethanolic extract standardized to 3.0% of triterpene glycosides, a liquid extract containing 2.5% of triterpene glycosides and a further liquid extract) were tested for their effects on the growth of EMT6 mouse mammary tumour cells, which are neither oestrogen- nor progesterone-dependent. None of the black cohosh extracts altered the growth or viability of EMT6 cells [Rockwell 2005].

- A 60%-ethanolic dry extract (4.5-8.5:1) from black cohosh was evaluated for growth-inhibitory activity in MCF-7 and T47D human breast cancer cell cultures and, at the gene expression level, for oestrogen-antagonistic effects utilizing an ERE-luciferase reporter assay. At concentrations of 10-200 µg/ml the extract inhibited cell proliferation (measured by incorporation of ^{3}H-thymidine into DNA de novo synthesis), markedly inhibited luciferase activity driven by the cyclin D1 promoter and increased transcriptional activity of the p21 gene promoter [Garita-Hernandez 2006].

- The ethyl acetate (EtOAc) fraction of an 80%-methanolic extract from black cohosh and the triterpene glycoside actein were tested, alone and in combination with chemotherapy agents, for inhibition of the growth of the ER^{-} Her2 overexpressing breast cancer cell line MDA-MB 453. Actein and the EtOAc fraction inhibited growth of the cancer cells and caused synergistic inhibition of tumour cell proliferation even at low concentrations (0.1-10 µg/ml) when combined with 5-fluorouracil, paclitaxel or doxorubicin [Einbond 2006].

- Breast cancer cell cultures (MCF-7 and MDA-MB-231) were exposed to various concentrations of black cohosh (root powder containing actein 1.08 mg/g, 27-deoxyactein 0.819 mg/g and cimifugosides 1.59 mg/g), oestradiol (E2) and tamoxifen to examine effects on cell proliferation using the sulforhodamine B (SRB) dye solution test. E2 at 10^{-10} to 10^{-8} M markedly stimulated the proliferation of MCF-7 cells ($p<0.01$). Black cohosh alone had no stimulatory effect, but significantly inhibited proliferation ($p<0.001$ at 1 mg/ml). Adding black cohosh at 0.001-1 mg/ml to E2 at 10^{-9} M resulted in dose-dependent inhibition of the E2 proliferative effect. Combinations of black cohosh with increasing tamoxifen concentrations further inhibited MCF-7 cell growth. Neither E2 nor tamoxifen had any detectable effect on MDA-MB-231 cells. However, black cohosh at 1 mg/ml inhibited MDA-MB-231 cell proliferation ($p<0.05$) and this inhibitory effect was enhanced by combinations of black cohosh with increasing tamoxifen concentrations [Al-Akoum 2007].

- The anti-invasive effects of a 40%-isopropanolic extract and its two major fractions, triterpene glycosides (TTGs) and cinnamic acid esters (CAE), on the highly invasive potential of MDA-MB-231 cells were studied in a membrane invasion culture system. Suppression of invasion by the extract reached 51.8% at 77.4 µg/ml. TTG and CAE reduced cell invasion by 34% and 25.5% respectively at 5 µg/ml [Hostanska 2007].

- A 60%-ethanolic dry extract dose-dependently inhibited not only the growth of MCF-7 and MDA-MB-231 breast cancer cells at 50 µg/ml and 100 µg/ml ($p<0.05$) but also the conversion of oestrone sulphate to active oestradiol in both cell lines ($p<0.05$) [Rice 2007].

- The effects of a 40%-isopropanolic extract on steroid sulphatase (STS) activity were studied in normal breast tissue obtained from pre- and postmenopausal women undergoing reduction mammoplasty. STS protein expression was studied by immunohistochemistry and western blotting. Treatment with the black cohosh extract at 0.1 mg/ml significantly reduced local oestrogen formation ($p<0.05$) [Stute 2007].

- Various black cohosh extracts induced inhibition of the growth of two human breast cancer cell lines: MDA-MB-453 (ER^-, Her2 over-expressing) and MCF-7 (ER^+, Her2 low). Using a Coulter counter assay IC_{50} values for inhibition of cell growth at 96 hours were determined as 30 µg/ml for a 100%-methanolic extract, 120 µg/ml for an 80%-methanolic extract, 50 µg/ml for a 70%-ethanolic extract and 200 µg/ml for a 40%-isopropanolic extract [Einbond 2007a].

- Extracts, fractions and isolated compounds from black cohosh were tested for growth inhibitory activity on the human breast cancer cell line MDA-MB-453 using several test systems. The results suggested that the growth inhibitory activity of black cohosh extracts is related to their triterpene glycoside composition. The effects of actein on MDA-MB-453 (ER^-, Her2 over-expressing) and MCF-7 (ER^+, Her2 low) human breast cancer cells were examined by fluorescent microscopy. Treatment with actein (IC_{50}: 8.4 µM) altered the distribution of actin filaments and induced apoptosis [Einbond 2008].

- Six marketed black cohosh preparations were evaluated for their content of characteristic marker substances and their effects on the proliferation of MCF-7 human breast cancer cells. Wide variations in content of triterpene glycosides and polyphenolic compounds were found. None of the products stimulated the proliferation of MCF-7 cells, measured by incorporation of ^{3}H-thymidine [Omer-Adam 2008].

In contrast, proliferative effects of black cohosh have been demonstrated in other studies.

- Using the MTT assay, 50%-ethanolic and 96%-ethanolic extracts from black cohosh at concentrations of 0.1-10 µg/ml and 0.01-1 µg/ml respectively caused proliferation of oestrogen receptor-positive MCF-7 human breast cancer cells; this effect was antagonized by the specific anti-oestrogen ICI 182,780 [Winterhoff 2002].

  In another study using the MTT assay, after determination of the optimum concentration of black cohosh for the culture of human breast cancer MCF-7 cells, growth curves of MCF-7 cells in the presence of black cohosh at 4.75 µg/litre or 17β-oestradiol at 0.3 nM were observed for 5 days. Cell growth had doubled after 32.1 and 31.7 hours in the presence of black cohosh and 17β-oestradiol respectively, compared to 35.3 hours in the blank control. Furthermore, from indirect immunofluorescence assay by flow cytometry, black cohosh at 4.75 µg/litre significantly increased oestrogen receptor levels in the MCF-7 cells ($p<0.01$ compared to control) [Liu ZP 2001].

  However, the suitability of the MTT assay for testing the ability of herbal extracts to influence cell proliferation has been questioned on the basis that it may lead to false positive results [Brugisser 2002].

- Fukinolic acid isolated from black cohosh increased the proliferation of oestrogen-dependent MCF-7 cells by up to 120% at 5×10^{-7} M ($p<0.05$) and 126% at 5×10^{-8} ($p<0.001$). While these effects were equivalent to the activity of oestradiol at a lower concentration of 10^{-10} M, fukinolic acid showed no significant activity at 5×10^{-9} M [Kruse 1999]. The oestrogenic activity of fukinolic acid and the 50% ethanolic extract could not be confirmed in subsequent experiments [Stromeier 2005].

A number of physiological mechanisms have been proposed for the anti-proliferative effects of black cohosh, as described below.

Cell cycle arrest by an 80%-methanolic extract [Einbond 2004] and induction of apoptosis by a 40%-isopropanolic extract [Hostanska 2004a] have been proposed as mechanisms of action for the anti-proliferative effect of black cohosh on human breast cancer cells. After evaluation of black cohosh-induced inhibition of proliferation of MCF-7 breast cancer cells by enzymatic assay using a tetrazolium salt, screening in the relevant dose range revealed annexin V expression and caspase activation indicative of apoptosis. Metabolic activation of the cells (with rat liver S9 homogenate containing P450 enzymes) did not abrogate or weaken the capacity of black cohosh to induce apoptosis, the extent of which (3-4 fold greater than in untreated control cells) was comparable to that of staurosporin. Induction of apoptosis was shown to be attributable to both triterpene glycosides and cinnamic acid esters [Hostanska 2004b].

Induction of apoptosis by black cohosh was observed in oestrogen receptor-negative as well as oestrogen receptor-positive cell lines. The authors suggested that this effect is independent of oestrogen receptors but is, however, of considerably higher specificity than found in parallel investigations with non-malignant cells [Hostanska 2004a]. Black cohosh inhibited proliferation and induced apoptosis in human prostate carcinoma cell lines, the effect being independent of androgen receptor status [Hostanska 2005]. In parallel, significant binding of compounds in a 50%-ethanolic black cohosh extract to the aryl hydrocarbon receptor ($p<0.05$ versus control) has been demonstrated; activation of this receptor is known to inhibit the growth of prostate cancer cells [Jarry 2005].

Two tests were performed to confirm the absence of intrinsic oestrogenic activity of black cohosh using MCF-7, T47D and MDA-MB-231 cells: an RNAse protection assay, which tests for regulation of the expression of oestrogen-responsive genes, and an oestrogen-responsive-element (ERE)-luciferase assay, which determines modulation of oestrogen receptor function by transactivation of the ERE. The rate of colony formation of oestrogen receptor-expressing breast cancer cells (Ishikawa cells) was used as an *in vitro* tool to investigate the propensity of tumour cells to metastasise. These assay systems did not show malignancy-increasing potential of black cohosh extracts [Lupu 2003].

Using a proliferation assay and gene expression microarray analysis it was clearly shown that a dichloromethane dry extract from black cohosh and isolated constituents inhibited the proliferation of MCF-7 human breast cancer cells. Gene expression profiling with the extract allowed identification of 431 regulated genes. The extract-induced expression pattern differed from those of 17β-oestradiol or tamoxifen (an oestrogen receptor antagonist). Enrichment of gene expression in an anti-proliferative and apoptosis-sensitizing manner was observed, as well as an increase in mRNAs coding for gene products involved in several stress response pathways. Thus antiproliferative and proapoptotic (but not oestrogenic) gene expression was demonstrated at the transcriptional level. Triterpene glycosides and their aglycones were identified as active principles [Gaube 2007].

In another experiment changes were identified in gene expression of MDA-MB-453 and MCF-7 human breast cancer cells induced by treatment with a pure methanolic black cohosh extract at 40 µg/ml. Six hours after treatment there was an increase in expression of ER stress (GRP78), apoptotic (GDF15), lipid biosynthetic (INSIG1 and HSD17B7) and phase 1 (CYP1A1) genes and after 24 hours a decrease in expression of cell cycle (HELLS and PLK4) genes. The microarray results were confirmed with RT-PCR. Thus the extract activated genes that enhance apoptosis and repressed cell cycle genes [Einbond 2007a].

In a comparable experimental procedure MDA-MB-453 cells were treated with actein at two concentrations, 20 or 40 µg/ml, for 6 or 24 hours. Several genes that play a role in stress response pathways were induced, whereas the cell cycle genes cyclin E2 and cell division cycle 25A were repressed. The results suggested that actein induces two phases of the integrated stress response, the survival phase and the apoptotic phase, depending on the concentration and duration of treatment [Einbond 2007b].

Oestrogen receptor affinity/activity
It is now known that there are at least two oestrogen receptors, ERα and ERβ. Many plant compounds show a greater affinity for binding to ERβ than to ERα [Kuiper 1998].

In 1985 a chloroform fraction from a methanolic extract of black cohosh was reported to exhibit binding to oestrogen receptors of the rat uterus; formononetin, reported as isolated from this fraction, exhibited weak binding to the receptors (1.15% of that of 17β-estradiol) [Jarry 1985b]. However, no formononetin has been detected in black cohosh in more recent investigations [Jiang 2006a, Jiang 2006b, Avula 2009, Kennelly 2002, Struck 1997]. A trace of formononetin (3.3 ppm) was reported in one other study [Panossian 2004], but none was detected in a subsequent study with a limit of detection as low as 0.08 ppm [Jiang 2006a].

A commercial black cohosh extract (not further defined) at 1:20 dilution to full strength did not inhibit [^{3}H]-oestradiol binding to cytosolic oestrogen receptor from livers of adult ovariectomized rats [Eagon 1996].

In a radioimmunoassay for determination of oestrogenic compounds, increasing sample volumes (5-100 µl) of two different 60%-ethanolic extracts from black cohosh dose-dependently displaced radioactively-labelled oestradiol bound to a specific oestradiol antiserum, paralleling the curve obtained with non-labelled oestradiol. This indicated competition with oestradiol for binding sites on the antibody molecules [Jarry 1995].

A methanolic extract from black cohosh gave negative results in assays for oestrogenic activity: no competitive binding affinity for recombinant human oestrogen receptors (ERα and ERβ) and no induction of alkaline phosphatase activity or up-regulation of progesterone receptor mRNA in cultured Ishikawa cells (an ER-positive endometrial adenocarcinoma cell line) [Liu J 2001].

In other investigations using oestrogen-dependent reporter gene assays or transcriptional activation assays black cohosh again showed no oestrogenic activity [Lupu 2003, Garita-Hernandez 2006].

The binding properties of three triterpene glycosides (cimicifugoside, cimiracemoside F and 27 deoxyactein) to the ligand binding domain of the oestrogen receptor ERβ were investigated by affinity ultrafiltration and LC/MS detection. Oestradiol and the phyto-oestrogens daidzein and genistein were used as positive controls. Neither the triterpene glycosides nor their enzymatically prepared aglycones bound to the ERβ, except for the aglycone of 27 deoxyactein, which showed weak binding affinity (4%). Metabolites of the aglycones, prepared by incubation with female human liver microsomes, were also found not to bind significantly to the ERβ [Onorato 2001].

An alcoholic extract (not further defined) from black cohosh at 1:500 dilution did not significantly transactivate human oestrogen receptors ERα or ERβ in a transient gene expression assay using HeLa cells co-transfected with an oestrogen-dependent reporter plasmid, whereas 17β-oestradiol at 10^{-9} M increased transcriptional activity by human ERα and ERβ by 20-fold and 10-fold respectively [Amato 2002].

To determine whether active substances present in a dry 58%-ethanolic extract of black cohosh bind to either of the two known subtypes of the oestrogen receptor (ERα and ERβ), subtype-specific oestrogen receptor ligand-binding assays were conducted using recombinant human ERα or ERβ. Although the extract displaced radiolabelled oestradiol from binding sites of cytosol preparations from porcine or human endometrium (containing both ERα and ERβ), no such displacement of oestradiol by the extract was achieved when either recombinant human ERα or ERβ was used. Dopaminergic activity of the black cohosh extract was demonstrated in an assay using recombinant human dopamine D_2 receptor protein and application of countercurrent chromatography to the extract enabled separation of oestrogenic and dopaminergic activities in two distinct fractions [Jarry 2003].

Expression patterns of two oestrogen-regulated gene products, truncated oestrogen receptor product 1 (TERP-1) and prolactin (PRL), were investigated in a rat pituitary gland-derived somatolactotrophic cell line. Treatment for 21 days with an isopropanolic extract from black cohosh or oestradiol induced significant upregulation of the two marker genes ($p<0.05$). This effect could be inhibited by simultaneous treatment with the antagonist faslodex. However, in contrast to the *in vitro* results, the extract did not mimic these gene regulatory properties in *in vivo* experiments using ovariectomized rats [Wober 2005].

Osteoprotective effects
Increased bone resorption mediated by osteoclasts is central to the pathogenesis of osteoporosis and under pathological conditions cytokines, particularly RANKL and TNFα, are often increased, leading to enhanced osteoclastogenesis. It has been demonstrated *in vitro* that 25-acetylcimigenol xyloside isolated from black cohosh potently blocks osteoclastogenesis induced by either RANKL or TNFα. This suppression of osteoclastogenesis results from abrogation of the NF-κB and ERK pathways induced by either RANKL or TNFα. Furthermore, 25-acetylcimigenol xyloside has been shown to attenuate TNFα-induced bone loss *in vivo* (see In vivo experiments) [Qiu 2007].

RANKL effects are physiologically counterbalanced by the glycoprotein osteoprotegerin, a potent inhibitor of bone resorption. In primary human osteoblasts a 40%-isopropanolic extract from black cohosh at concentrations between 0.75 and 750 µg/litre significantly upregulated the antiresorptive cytokine osteoprotegerin ($p<0.001$) in a similar manner to oestradiol or raloxifene, increased osteoprotegerin protein secretion ($p<0.001$) and enhanced two osteoblastic differentiation markers ($p<0.001$), bone-specific alkaline phosphatase activity and osteocalcin expression. These effects were completely abolished by co-incubation with faslodex, a selective oestrogen receptor down-regulator [Viereck 2005].

Neurovegetative pathways
It has been demonstrated that black cohosh may contain (as yet unidentified) compounds with dopaminergic effects [Winterhoff 2002; Jarry 2003]. Further studies have shown that extracts from black cohosh bind to GABA, serotonin, dopamine and acetylcholine receptors. Follow-up investigations into the cellular functions which might be induced by receptor binding, revealed, for example, partial agonistic effects of extracts at the serotonin receptor and inhibition of catecholamine secretion [Winterhoff 2003, Burdette 2003, Jarry 2003, Woo 2004, Nisslein 2006].

Black cohosh has been shown to act as a mixed competitive ligand and partial agonist of the serotonin receptor. Receptor subtype-specific IC_{50} values were 2.4 µg/ml for the human 5-HT_7 receptor and 13.9 µg/ml for the rat 5-HT_{1A} receptor. Via the 5-HT_7 receptor black cohosh also elevated intracellular cAMP levels; this effect was reversed by the specific antagonist methiothepin, suggesting receptor-mediated agonistic properties for black cohosh [Burdette 2003].

The binding of a 40%-isopropanolic extract from black cohosh to 21 sub-types of three classes of CNS receptors (dopamine, 5-HT and GABA) was evaluated by displacement of radio-labelled receptor ligands. The extract showed the highest affinities (IC_{50} values less than 15 µg/ml) towards 5-HT_{1A}, 5-HT_{1D}, 5-HT_7 and $GABA_A$ receptors; it did not influence serotonin transport nor interfere with serotonin secretion or release [Nisslein 2006].

It has also been demonstrated that black cohosh behaves as a mixed competitive ligand and partial agonist at the human μ opiate receptor expressed in Chinese hamster ovary cells. At 0.3 mg/ml three different extracts from black cohosh, prepared with 100% methanol, 75% ethanol or 40% isopropanol, effectively displaced the binding of a μ opiate receptor-specific ligand (a synthetic peptide) to the receptor. The 75%-ethanolic extract displaced this ligand with an IC_{50} of 165.9 µg/ml and, in a different assay, was shown to act as an agonist at the human μ opiate receptor. Because the opiate system in the brain is intimately associated with mood, temperature and sex hormone levels, the authors considered these results to be consistent with the effects of black cohosh in alleviating some menopausal symptoms [Rhyu 2006].

Black cohosh extracts (100%-methanolic and 75%-ethanolic) and their constituents were evaluated for serotonergic activity using 5-HT_7 receptor binding, cAMP induction and serotonin selective re-uptake inhibitor (SSRI) assays. Crude extracts displayed 5-HT_7 receptor binding activity and induced cAMP production. Triterpenoids and phenolic acids bound weakly to the 5-HT_7 receptor but exhibited no cAMP or SSRI activity. In contrast, N_ω-methylserotonin (identified as a minor constituent of black cohosh) showed 5-HT_7 receptor binding (IC_{50}: 23 pM), induced cAMP (EC_{50}: 22 nM) and blocked serotonin re-uptake (IC_{50}: 490 nM) [Powell 2008].

Cimicifugoside inhibited catecholamine secretion, as well as increases in calcium (IC_{50}: 18 µM) and sodium (IC_{50}: 2 µM), induced in bovine adrenal chromaffin cells by the nicotinic acetylcholine receptor agonist DMPP (1,1-dimethyl-4-phenylpiperazinium iodide). The results suggested that cimicifugoside binds to the nicotinic acetylcholine receptor in a non-competitive way [Woo 2004].

Vasoactive effects
Isolated fukinolic acid and cimicifugic acid D at a concentration of 3×10^{-4} M caused sustained relaxation of rat aortic strips precontracted with norepinephrine; cimicifugic acids A, B and E and fukiic acid showed no vasoactivity at this concentration [Noguchi 1998].

Antioxidant activity
A methanolic extract from black cohosh scavenged 1,1-diphenyl-2-picrylhydrazyl (DPPH) free radicals with an IC_{50} of 99 µg/ml, and at concentrations up to 200 µg/ml dose-dependently inhibited DNA single-strand breaks and oxidation of DNA bases induced by menadione. Of nine hydroxycinnamic acid derivatives identified as antioxidants in the extract, six reduced menadione-induced DNA damage in cultured S30 breast cancer cells, the most potent being methyl caffeate, caffeic acid and ferulic acid [Burdette 2002].

Hepatic effects
A 60%-ethanolic dry extract (4.5-8.5:1) from black cohosh was tested for cytotoxicity, mitochondrial toxicity and apoptosis/necrosis using the human liver cancer cell line HepG2. Cytotoxicity was apparent at concentrations ≥ 75 µg/ml and mitochondrial β-oxidation was impaired at concentrations ≥ 10 µg/ml. The mitochondrial membrane potential was decreased at concentrations ≥ 100 µg/ml and oxidative phosphorylation was impaired at concentrations ≥ 300 µg/ml. The mechanism of cell death was predominantly apoptosis [Lüde 2007].

The growth of human HepG2 liver cancer cells was not inhibited by 75%- or 80%-ethanolic extracts or a 40%-isopropanolic extract from black cohosh at concentrations up to 50 µg/ml [Huang 2010]. In another study actein was found to inhibit the growth of HepG2 cells with an IC_{50} of 27 µg/ml (40 µM) [Einbond 2009].

In vivo experiments

Influence on breast cancer
As an oestrogen receptor-positive breast cancer model, mammary tumours were induced in female rats by intragastric administration of 7,12-dimethylbenz[*a*]anthracene (DMBA), then the animals were ovariectomized, allowed to recover, randomized into groups and treated orally for 6 weeks with an isopropanolic extract from black cohosh at daily dose levels of 0.714, 7.14 or 71.4 mg/kg (comparable to 1, 10 or 100 times the human therapeutic dose respectively) or with mestranol (an oestrogenic steroid) at 450 µg/kg/day as a positive control, or vehicle only as a negative control. Six weeks later, whereas tumour growth had been stimulated in the mestranol-treated group ($p<0.05$), no significant differences in the number or size of tumours could be detected between the black cohosh groups and the vehicle-only control group. A trend towards tumour reduction was observed in the black cohosh groups compared to the control. Serum levels of prolactin, follicle-stimulating hormone (FSH) and luteinizing hormone (LH), organ weights and endometrial proliferation were unaffected by the extract in comparison with the vehicle-only group [Freudenstein 2002].

Sexually mature female MMTV-*neu* transgenic mice were used in another study; these mice develop primary and metastatic mammary tumours by spontaneous activation of the proto-oncogene *neu* (c-erbB2, the rodent homologue of HER2), the most common oncogene of breast cancer. An isopropanolic extract from black cohosh, administered orally to the mice in the diet at an amount corresponding to 40 mg of rhizome and root per 1800 calories of diet (correlating to 40 mg/day in women) from 2 months of age until the maximum age of 16 months, did not alter the incidence of mammary tumours compared to controls: 118 out of 127 mice (92.9%) in extract-treated animals; 123 out of 131 mice (93.9%) in control animals. Tumour latency was also comparable in the two groups. However, mice treated with black cohosh had a significantly higher incidence of lung metastatic lesions that were grossly visible at necroscopy ($p<0.002$) and detected by histopathology ($p<0.001$). It has not yet been determined whether black cohosh accelerated the development of metastatic disease or increased its incidence, nor whether the observed metastatic effects in this transgenic model could predispose to the development of tumours [Davis 2008]. These effects require further investigation.

After treatment of ovariectomized rats with a 60%-ethanolic extract from black cohosh at 30 mg/day for 3 months no proliferative or oestrogenic effects of the extract on the mammary gland were evident from morphometric analysis [Seidlova-Wuttke 2008].

Influence on tumours
As an animal model of endometrial cancer, highly metastasizing, hormone-responsive RUCA-I rat endometrial adenocarcinoma cells were subcutaneously implanted into ovariectomized rats of the syngeneic DA/Han strain. The rats (5-6 per group) were then given one of four treatments for 5 weeks: an isopropanolic liquid extract from black cohosh (an amount corresponding to herbal drug at 60 mg/kg), tamoxifen (subcutaneously at 200 µg/kg), a combination of the extract and tamoxifen, or isopropanol only as a control. Tumour growth was comparable in rats treated with the extract and those in the control group whereas tamoxifen, in its role as an endometrium-specific oestrogen-agonist, accelerated tumour growth and metastasis formation. The mean tumour mass was 550 mg in animals treated with the black cohosh extract, 660 mg after tamoxifen, 590 mg after the tamoxifen-extract combination and 570 mg in the control group. Pulmonary metastases were found in all groups. In the control and tamoxifen groups respectively, 3 and 4 of the animals showed pulmonary metastases; additionally 2 abdominal metastases were found in tamoxifen-treated animals. In the extract group 2 animals and in the tamoxifen-extract combination group 1 animal produced metastases. The extract did not influence the growth of primary tumours and the tendency to metastasize was reduced, irrespective of whether black cohosh was administered alone or in combination with tamoxifen [Nisslein 2004].

Endocrine activities
A 60%-ethanolic black cohosh dry extract administered intraperitoneally to ovariectomized rats at 2 × 12 mg per animal (approx. 2 × 48 mg/kg body weight) daily caused a significant decrease in serum concentration of luteinizing hormone (LH) after 3 days; the mean LH level was 332 ng/ml in extract-treated animals compared to 781 ng/ml in control animals ($p<0.01$). However, no significant differences in LH from control levels were evident after 1 or 14 days, and no significant changes were observed in serum levels of follicle stimulating hormone (FSH) or prolactin [Jarry 1985a, Jarry 1995].

The chloroform-soluble dry fraction from a methanolic extract of black cohosh (crude drug to chloroform fraction ratio approx. 35:1), administered intraperitoneally to ovariectomized rats in 9 divided doses over 4 days (a total dose of 108 mg per animal corresponding to approx. 568 mg/kg body weight), reduced serum levels of LH from 657 ng/ml (injection vehicle as control) to 339 ng/ml [Jarry 1985b].

Oral administration of a 50%-ethanolic black cohosh extract at 6, 60 or 600 mg/kg body weight/day to immature mice for 3 days followed by uterus weight tests, and subcutaneously to mature ovariectomized rats followed by vaginal smear tests, did not reveal any oestrogenic effects [Einer-Jensen 1996]. In another study, oral administration of a 50%-ethanolic extract from black cohosh to ovariectomized female mice at 50-600 mg daily for 3 days did not produce any oestrogenic effects (cornification) in vaginal smears [Knüvener 2000].

Treatment of ovariectomized mice with 500 µl of an alcoholic black cohosh extract (not further defined) by oral gavage daily for 4 days did not increase uterine weight compared to untreated controls, whereas 17β-oestradiol administered subcutaneously at 100 µg/kg/day caused a 1.7-fold increase [Amato 2002].

Ovariectomized rats were treated for 17 days with a 40%-isopropanolic extract, alone or in combination with the anti-oestrogen fulvestrant, and the effects were investigated by vena cava and uterine gene expression analysis using real-time PCR. Treatment with the extract or fulvestrant, or a combination of both, did not lead to significant changes in uterine weight. Black cohosh showed no or only slight anti-oestrogenic effects on gene expression in the uterus [Kretzschmar 2005].

In contrast, when black cohosh was administered to immature female mice by gavage at 75, 150 or 300 mg/kg body weight daily for 14 days, uterine weights (measured when oestrus was observed) increased with the increasing dosage of black cohosh and the duration of oestrus was significantly extended in the 300 mg/kg group ($p<0.05$) [Liu ZP 2001].

The partly conflicting results of experiments described above may be explained by the concept of the Selective Estrogen Receptor Modulator (SERM) [Kuiper 1998, Winterhoff 2002, Wuttke 2003a, Wuttke 2003b, Seidlová-Wuttke 2003b]. Since oestrogen receptors are expressed differently in various organs, oestrogenic effects of a substance need to be assessed for each individual tissue; the same substance can exert oestrogenic and non- or anti-oestrogenic effects depending on the specific tissue. This may explain observations of both oestrogenic and anti-oestrogenic effects of black cohosh [Boblitz 2000].

Effects on the nervous system
In a systematic review of 15 *in vitro* and 15 *in vivo* studies it was concluded that black cohosh exerts a central activity rather than a hormonal effect [Borrelli 2003].

Hot flush equivalents in ovariectomized rats (rapid and short-term increases of more than 1°C in subcutaneous body temperature, measured by an implanted temperature sensor and transmitter) were reduced in frequency by oestradiol valerate (2 mg/kg/day; $p<0.05$) or the antidopaminergic drug veralipride (100 mg/kg/day), indicating a response and sensitivity comparable to hot flushes in women. Oral administration of a 58%-ethanolic dry extract of black cohosh to the rats at 100 mg/kg body weight daily for 5 days also significantly reduced the number of hot flush equivalents per day ($p<0.05$ on days 3-5); the frequency returned to pre-treatment levels after cessation of treatment [Winterhoff 2003].

In a subsequent study using the same extract and a similarly implanted sensor and transmitter, subcutaneous temperatures measured at 5-minute intervals in individual *intact* rats were found to be stable for periods of 3 hours. Following ovariectomy, temperature pulses appeared with peaks occurring every 20-40 minutes, but these peaks were not seen in rats treated with the extract at 25 mg/animal/day in food. Over a study period of 3 weeks ovx rats had a significantly higher mean temperature than intact ($p<0.05$) or ovx + extract-treated rats ($p<0.001$), but there was no significant difference between the body temperatures of intact and ovx + extract-treated rats [Kapur 2010].

An extract of black cohosh orally administered to mice at 25-100 mg/kg body weight caused a distinct and dose-dependent fall in body temperature one hour after gavage, 100 mg/kg having an effect comparable to that of bromocriptine (a dopamine D_2 agonist) given intraperitoneally at 5 mg/kg. The fall in body temperature was inhibited by pretreatment with the dopamine D_2/D_3 receptor antagonist sulpiride at 100 mg/kg, but not by the selective D_1 receptor antagonist SCH 23390.
Furthermore, the extract prolonged ketamine-induced sleeping time in mice, an effect which also occurred after bromocriptine injection but could be blocked by sulpiride and was unchanged by SCH 23390. These results indicated central activity of the extract mediated by central D_2 receptors [Löhning 1999].

Osteoprotective effects
Ovariectomized female rats fed on a soya-free diet were given one of three treatments daily for 12 weeks: a 40%-isopropanolic extract from black cohosh corresponding to 4.5 mg/kg of

triterpene glycosides, raloxifene (a known SERM; 3 mg/kg intragastrically) or soya-free diet only. Post-mortem femoral bone density and bone mineral density at the lumbar vertebral site were determined by computed tomography. Mechanical resistance to fracture of the femoral head was assessed in a material testing device. Urinary pyridinoline (PYR) and deoxypyridinoline (DPY), breakdown products of collagen during bone resorption serving as specific markers of bone loss, were determined by HPLC at baseline and at weekly intervals. The black cohosh extract induced a significant improvement in overall bone quality score ($p<0.05$) and significantly reduced the urinary content of PYR and DPY ($p<0.05$). Comparable results were obtained in the raloxifene group [Nisslein 2003].

Treatment of ovariectomized rats with a black cohosh extract, added to food at 33 mg/day per animal for 3 months, had osteoprotective effects; compared to ovariectomized controls, significant reductions in loss of bone mineral density in tibia ($p<0.05$) and reduced serum levels of osteocalcin (a marker of bone turnover produced by osteoblasts; $p<0.05$) were observed. The extract also significantly reduced paratibial (foreleg) and abdominal fat (both $p<0.05$) and hence body weight ($p<0.05$), and also serum concentrations of the hormone leptin (an indicator of lipocyte activity; $p<0.05$). Oral 17β-oestradiol at 0.325-0.35 mg/day per animal had similar and somewhat stronger effects but, in contrast to the black cohosh extract, also reduced serum crosslaps (a marker of bone turnover produced by osteoclasts; $p<0.05$) and significantly increased uterine weight ($p<0.05$). Furthermore, oral 17β-oestradiol influenced the expression of oestrogen-regulated uterine genes, thereby inhibiting ERβ ($p<0.05$) and stimulating IGF-1 (insulin-like growth factor, which stimulates proliferation of the endometrium; $p<0.05$). Since the black cohosh extract exerted significant oestrogenic effects in the bone (particularly in osteoblasts, cells which rebuild absorbed bone) and fat tissue of ovariectomized rats, but not in the uterus, it appeared to contain organ-specific SERMs with effects in some, but not all, oestrogen-sensitive organs [Seidlova-Wuttke 2003a, Seidlova-Wuttke 2003b].

Female 12-week-old rats were ovariectomized (n = 36) or sham-operated (n = 12) and, under the same anaesthesia, all 48 animals underwent a standardized metaphyseal tibial osteotomy (a cut through the bone) and osteosynthesis by bridging with a five-hole, T-shaped titanium plate. The healing process was then investigated over a period of 35 days during which the sham-operated rats were fed a phytoestrogen-free diet, while groups of 12 ovariectomized rats received the same phytoestrogen-free diet, alone or supplemented with 17β-oestradiol 3-benzoate (approx. 0.03 mg/kg body weight per day) or a 50% V/V-ethanolic black cohosh dry extract (approx. 24.9 mg/animal/day). Black cohosh induced a high rate of metaphyseal callus formation. The biomechanical properties and amount of new callus indicated that fracture healing was still in progress, therefore gene expression of osteoblasts was comparatively high. However, osteoporotic metaphyseal fracture healing was improved more by oestrogen than by black cohosh and the authors considered the 5-week duration of treatment to be too short for black cohosh to show its full potential [Kolios 2010a].

In a related study by the same authors, another 36 female 12-week-old rats were ovariectomized and over a period of 10 weeks on a standard diet of phytoestrogen-free food they developed severe osteopenia with about 40% loss of bone mineral density in the proximal tibia. All animals subsequently underwent the metaphyseal tibial osteotomy and T-plate osteosynthesis, and in groups of 12 were treated for 35 days with the standard diet, alone or supplemented with 17β-oestradiol or the black cohosh extract. Black cohosh did not exhibit positive effects in severe (senile) osteopenic fracture healing, as it had done in early (postmenopausal) osteoporotic fracture in rats [Kolios 2010b].

From a review in 2003 it was concluded that in ovariectomized rats a black cohosh extract showed many of the beneficial effects of 17β-oestradiol, including effects in the brain/thalamus to reduce serum LH levels, effects in the bone to prevent osteoporosis and oestrogenic effects in the urinary bladder, but had no uterotrophic effect [Wuttke 2003a].

25-Acetylcimigenol xyloside dissolved in dimethyl sulfoxide (DMSO) was administered intraperitoneally to mice at 12 mg/kg body weight for 5 days, with or without supracalvarial injection of TNFα, while other groups received TNFα + DMSO, DMSO only, or no treatment. Histological assessment of the percentage of bone surface covered by osteoclasts in the calvaria of each group revealed that the extent of osteoclastogenesis induced by TNFα + DMSO was significantly reduced in mice treated with 25-acetylcimigenol xyloside + TNFα + DMSO ($p<0.04$), while DMSO alone had no impact [Qiu 2007].

Hepatic effects

After oral administration of a 60%-ethanolic black cohosh dry extract to rats at daily dose levels of 1, 10, 100, 300 and 1000 mg/kg body weight for 21 days, electron microscopy of liver sections revealed microvesicular steatosis of hepatocytes only in animals treated with the extremely high daily dose of 1000 mg/kg.

It is important to note that the abstract in the original paper incorrectly cited the daily dose causing microvesicular steatosis as "> 500 µg/kg body weight"; a correction was published three years later [Lüde 2007].

No effects on liver morphology or hepatic function indices were evident in rats after administration by gavage of a 50%-ethanolic dry extract of black cohosh at 300 mg/kg/day for 30 days [Mazzanti 2008].

Actein was administered orally to rats at 35.7 mg/kg body weight, while control groups received only water, and separate groups of animals were tested after 6 hours and 24 hours. Using labelled complementary DNA (cDNA) generated from the liver tissue of each study animal, chemogenomic analyses indicated that actein elicited stress- and statin-associated responses in the liver, altering the expression of cholesterol and fatty acid biosynthesis genes and various other genes. Consistent with these findings, a 0.6-fold decrease in levels of cholesterol ($p<0.018$) and free fatty acids ($p<0.012$) in the liver was found after 24 hours, with no change in triglyceride content [Einbond 2009].

Other effects

In the tail suspension test in mice (a behavioural test for antidepressant activity) a 58%-ethanolic dry extract from black cohosh, administered by gavage at 50 or 100 mg/kg, reduced the period of immobility ($p<0.05$), as did imipramine at 30 mg/kg ($p<0.05$); this effect was observed 60 minutes after a single dose and also after 8 days of treatment [Winterhoff 2003].

In studies of gene expression in the *vena cava* of ovariectomized rats, treatment of the animals for 17 days with a 40%-isopropanolic extract (a daily amount corresponding to black cohosh at 60 mg/kg body weight) did not cause any changes in mRNA expression of ERα, clusterin, NOS3 (endothelial NO synthase), KI67, PCNA and VEGF. In contrast, a slight downregulation of COX2 and ACE (angiotensin converting enzyme) mRNA expression was found. As these effects were not abrogated by co-treatment with the antiestrogen fulvestrant, they cannot be attributed to oestrogen receptor interactions alone. Furthermore, unlike oestradiol, black cohosh treatment slightly upregulated C3 mRNA expression suggesting that this effect is also not mediated by oestrogen receptor interaction. Therefore, long-term administration of black cohosh did not change mRNA

expression of specific oestrogen-sensitive genes in the vascular system [Kretzschmar 2005].

Another study investigated whether extracts from black cohosh altered the response of EMT6 mouse mammary tumour cells to radiation or to four drugs commonly used in cancer therapy. The extracts increased the cytotoxicity of doxorubicin and docetaxel and decreased the cytotoxicity of cisplatin, but did not alter the effects of radiation or 4-hydroperoxycyclophosphamide. The interaction between black cohosh and cisplatin was seen only at a high concentration (100 times the therapeutic level), which can be regarded as not clinically relevant [Rockwell 2005].

Pharmacological studies in humans

Serum levels of pituitary gonadotropins (FSH and LH), prolactin, oestradiol, cortisol, lipids and liver transaminases (glutamate-oxalacetate transaminase and glutamate-pyruvate transaminase) were determined, and endometrial thickness measured by ultrasonography, at baseline and at the end of a 3-month randomized study in which postmenopausal women with climacteric complaints received daily either a 40%-isopropanolic black cohosh extract (corresponding to 40 mg of dried rhizome, n = 32) or an oestradiol treatment (n = 32). In the black cohosh group after 3 months total cholesterol was unchanged, while a slight but significant increase in HDL-cholesterol ($p<0.04$) and a decrease in LDL-cholesterol ($p<0.003$) were observed. No significant changes were evident in triglycerides, FSH, LH, prolactin, oestradiol or cortisol, and liver function and endometrial thickness were not affected. Efficacy data from this study are summarized under Clinical studies [Nappi 2005].

In conjunction with a placebo-controlled clinical study [Newton 2006, summarized under Clinical studies], in which a total of 235 peri- and postmenopausal women were assigned to daily treatment for 12 months with black cohosh extracts corresponding to 160 mg (alone) or 200 mg (in combination with other herbal ingredients) of herbal drug, the opportunity was taken to examine the effect of black cohosh on various serum parameters between baseline and the 3-month stage. No significant differences were found between the herbal and placebo groups with respect to serum total cholesterol, LDL, HDL, triglycerides, glucose, insulin or fibrinogen [Spangler 2007].

In a 12-week randomized, double-blind study in postmenopausal women neither a 58%-ethanolic dry extract from black cohosh (daily dose equivalent to 2 × 20 mg of crude drug, n = 20) nor placebo (n = 20) influenced endometrial thickness, measured by transvaginal ultrasound, whereas conjugated oestrogens (CE, 2 × 0.3 mg daily, n = 22) increased endometrial thickness by more than 1 mm. The black cohosh extract slightly increased the amount of superficial cells in vaginal smears (10% increase from baseline; $p = 0.0542$) compared to a significant increase of 38% after CE ($p<0.01$) and a decrease of 10% after placebo.

Analysis of markers of bone metabolism in serum indicated beneficial effects in both the black cohosh and CE groups. Serum levels of "CrossLaps" (metabolic products of bone-specific collagen-1α1, generally accepted as markers of bone degradation) showed little change after black cohosh, whereas treatment with CE produced a significant decrease in CrossLaps after 4 and 12 weeks ($p<0.05$) compared to an increase in the placebo group. On the other hand serum levels of bone-specific alkaline phosphatase, a metabolic marker for bone formation, increased significantly in the black cohosh group over the 12 weeks ($p<0.05$ vs. placebo) while increasing only slightly in the CE group and remaining almost unchanged in the placebo group. Combined as a Bone Turnover Index, i.e. log (bone-specific alkaline phosphatase/CrossLaps), the beneficial effects on bone metabolism after black cohosh or CE were comparable and significant ($p = 0.0138$ vs. placebo in both cases). No significant effects were observed on coagulation markers or liver enzymes in the blood. Efficacy data from this study are summarized under Clinical studies [Wuttke 2003b, Wuttke 2006b].

Treatment of 45 healthy postmenopausal women with a 40%-isopropanolic extract of black cohosh (corresponding to 40 mg of the herbal drug) daily for 3 months also had a favourable effect on bone markers, producing a significant decrease in urinary concentration of N-telopeptides ($p<0.05$), a marker of bone resorption, and an increase in serum alkaline phosphatase ($p<0.05$), a marker of bone formation, in comparison with 37 women participating as untreated controls. These biochemical changes would be consistent with a small protective effect against the increased bone loss that occurs after menopause.

However, addition of serum from treated women to a murine osteoblastic cell line did not confirm any effect on osteoblasts; no differences between groups were observed with respect to effects on the activity of alkaline phosphatase or the expression of three genes related to osteoblastic differentiation and function.

Compared to baseline, no significant differences were found after 3 months in routine serum biochemical parameters, lipid profiles or hormone levels (oestradiol, testosterone, FSH and parathyroid hormone) within or between the two groups of women [García-Pérez 2009].

The effects of black cohosh on circulating and breast-specific oestrogenic markers were investigated during the course of an open clinical study in which 61 women (aged 36-62 years) with daily menopausal symptoms, natural or following surgery, took a black cohosh extract (2 × 40 mg) daily for 12 weeks followed by a 12-week wash-out phase (a total of 24 weeks of assessment). Specimens of blood and nipple aspirate fluid were collected at baseline and at 4,12 and 24 weeks. Serum oestradiol, pS2 protein (a marker of oestrogenic activity), FSH and LH showed no significant changes during black cohosh treatment. Nipple aspirate fluid was assayed for changes in oestrogenic markers and the epithelial cells in it were studied for changes in proliferation; no significant effects on pS2 or cellular morphology were detected. Efficacy data from this study are summarized under Clinical studies [Ruhlen 2007].

Physiological parameters were evaluated over the course of a clinical study involving peri- and post-menopausal women with climacteric symptoms, who were randomized to daily treatment for 24 weeks with a 40%-isopropanolic black cohosh extract at dose levels corresponding to either 39 mg (n = 76) or 127.3 mg (n = 76) of herbal drug. No significant changes in serum levels of oestradiol, FSH, LH, prolactin or sexual hormone binding globulin were detected in either group compared to pre-treatment levels. Vaginal cytological parameters also remained unchanged [Liske 2002].

In contrast, in an earlier placebo-controlled study in menopausal women (mean age 52 years), a significant decrease was reported in serum LH levels ($p<0.05$) in the verum group (n = 55) compared to the placebo group (n = 55) after daily oral administration of 8 mg of a hydroethanolic extract of black cohosh for 2 months. FSH levels remained similar in the two groups [Düker 1991].

A pilot study using positron emission tomography neuroimaging to examine central opioid function in 5 postmenopausal women demonstrated that a black cohosh 40%-isopropanolic extract (2 × 20 mg taken daily for 30 days) had a direct neuropharmacological action on the brain and that the effects are mediated via alterations in μ-opioid receptor binding potential. The brain regions affected comprise areas which show similar responses to oestrogen, areas involved in emotional and cognitive function

and areas involved in the placebo response. Black cohosh did not exhibit direct central oestrogen-like effects [Reame 2008].

Clinical Studies

According to the EMEA's *Guideline on Clinical Investigation of Medicinal Products for Hormone Replacement Therapy of Oestrogen Deficiency Symptoms in Postmenopausal Women* enrolled subjects should have a defined minimum number of hot flushes per day at baseline (at least 5 moderate to severe hot flushes) to justify a need for treatment. The proposed primary endpoint for efficacy is the frequency of moderate to severe hot flushes. As a secondary endpoint the Kupperman Menopausal Index or other fully validated scales can be used. A duration of treatment of 3 months is generally recommended for symptom efficacy evaluation [European Medicines Evaluation Agency 2005].

Note: Throughout this section the abbreviation "KM Index" refers to the Kupperman Menopausal Index

Clinical studies performed with a 40%-isopropanolic dry extract of black cohosh (daily dose corresponding to 40 mg of herbal drug)

In a double-blind, placebo-controlled study 304 patients with climacteric complaints (including a median of 28 hot flushes per week) were randomized to treatment with the black cohosh extract (n = 153) or placebo (n = 151) daily for 3 months. Assessment of efficacy from changes in the Menopause Rating Scale (MRS) from baseline to end of treatment showed a significant difference in favour of the active treatment after 3 months ($p = 0.027$). A relevant increase in the treatment difference with declining baseline FSH level was also observed. Analysis of MRS subscores revealed that "hot flushes" ($p = 0.007$), "atrophy" ($p = 0.012$) and "psyche" ($p = 0.019$), but not "soma", decreased significantly in the black cohosh group compared to the placebo group [Osmers 2005].

A randomized, double-blind study conducted in 5 centres in China involved 244 patients aged 40-60 years with menopausal complaints. At baseline the interval since last regular menstruation was more than 5 months. The patients were treated with either the black cohosh extract (n = 122) or tibolone (2.5 mg/day, n = 122) for 12 weeks. The efficacy of tibolone (a synthetic steroid used as HRT) in climacteric complaints has been extensively confirmed by placebo-controlled studies [Borrelli 2008a]. A benefit-risk balance was the primary endpoint, calculated as a composite from the KM Index total score and the frequency of adverse events. KM Index total scores decreased substantially in both groups with no significant differences between groups at the 4-week and 12-week time points; from 24.7 at baseline the scores after 12 weeks were 7.7 in the black cohosh group and 7.5 in the tibolone group. Since the incidence of adverse events was significantly lower in the black cohosh group ($p<0.001$) the benefit-risk balance for black cohosh was non-inferior and even superior to tibolone ($p_{non\text{-}inferiority}<0.0001$ and $p_{superiority} = 0.0088$ in per protocol patients). KM Index responder rates were similar in the two groups (84% and 85%) [Bai 2007].

In another randomized study 64 postmenopausal women with climacteric complaints received daily for 3 months either the black cohosh extract (n = 32) or low-dose transdermal oestradiol (25 µg, n = 32) every 7 days plus dihydrogesterone at 10 mg/day for the last 12 days of the 3-month oestradiol treatment. The patients recorded the number of hot flushes per day in a diary. Other climacteric symptoms (vasomotor and urogenital symptoms) using the Greene Scale, and anxiety and depression using the Symptom Rating Test, were evaluated at baseline and after 3 months. Both treatments significantly reduced the number of hot flushes per day ($p<0.001$) and vasomotor symptoms ($p<0.001$) by the end of the first month, and this positive effect was maintained throughout the 3 months of observation without any significant difference between treatments. Identical effects were evident in the black cohosh and oestradiol groups for anxiety ($p<0.001$) and depression ($p<0.001$) [Nappi 2005].

In an open observational study 6,141 women with climacteric complaints were treated (in 1,287 outpatient gynaecologists' practices, with the choice of treatment at the discretion of participating physicians) over a period of approx. 6 months with either a mono-preparation containing the black cohosh extract (recommended daily dose: 2 tablets, corresponding to 2 × 20 mg of dried rhizome; n = 3,027) or a combination preparation, tablets each containing 3.75 mg of the black cohosh extract and 70 mg of an ethanolic St. John's wort extract 3.5-5:1 (recommended daily dose: 2 × 1-2 tablets; n = 3,114). The patients (average age 52 years) had been suffering from climacteric complaints for 2.5 years on average; 27% had previously been treated with HRT and 8% with herbal remedies; 8% reported breast cancer during the anamnesis. Changes of dose or study therapy were permitted if considered necessary by the physician. Concomitant use of HRT therapy was not allowed during the study period. Drop-out rates were 15% with monotherapy and 11% with combination treatment, thus 5,373 patients were analyzed after 6 months.

Efficacy was evaluated using the Menopause Rating Scale (MRS) with assessments at 0, 3 and 6 months; a subset of patients (n = 736) treated for a further 6 months was also analysed after 12 months of therapy. The primary efficacy variable was the MRS "psyche" subscore, which covers symptoms of depressive mood, nervousness and nervous irritability, and generally impaired performance and memory. At baseline the MRS total score was assessed as less "severe" in the mono-product group (0.30 ± 0.17) than in the herbal combination group (0.36 ± 0.17). The "psyche" subscore was also differently distributed: symptoms were "mild" (0.31 ± 0.22) in the mono-group, compared to "moderate" (0.42 ± 0.23) in the group receiving the combination with St. John's wort (the latter treatment being mainly used for patients with more pronounced mood complaints).

Symptom scores improved substantially from baseline with both treatments. The MRS "psyche" subscore decreased under monotherapy to 0.21 ± 0.18 after 3 months and to 0.16 ± 0.14 after 6 months, and under combination therapy to 0.26 ± 0.18 and 0.19 ± 0.15 respectively. After adjustment for differences in baseline scores, the reductions from baseline were still significantly greater in the combination group ($p<0.001$ after 3 months). In the subset of patients followed up after 12 months the improvement from both therapies was maintained. In this study, therefore, both treatments were effective but the combination of black cohosh and St. John's wort was superior to black cohosh alone in alleviating climacteric mood symptoms [Briese 2007].

A total of 2,016 Hungarian women aged 40-65 years with moderate menopausal complaints were enrolled in a post-marketing surveillance study of the effects of the black cohosh extract. The inclusion criteria were a KM Index score ≥ 20 and refusal (74.5%) or contraindication (25.5%) of oestrogen therapy. The daily dose of extract corresponded to 40 mg of black cohosh and the severity of complaints was evaluated on commencement and at the end of weeks 4, 8 and 12. Data from 1,876 patients were completely evaluated. From the mean KM Index score of 28.00 points at week 0, the average decrease in the Index was 17.64 points after 12 weeks ($p<0.001$): 8.12 points after 4 weeks, a further 5.56 points after 8 weeks and a further 3.96 points after 12 weeks. The most favourable changes in weighted symptom scores were decreases of 6.32 in hot flushes,

2.86 in night sweating, 2.27 in insomnia and 2.0 in anxiety ($p<0.001$ in each case). Improvements were also experienced in palpitations (0.84), depression (0.72) and headache (0.69). The KM Index scores of almost half of the women included in the study decreased by more than 18; no improvement was evident in 11 patients (0.55%) and symptoms became more severe in 6 (0.30%) [Vermes 2005].

Women with menopausal complaints (n = 502; mean age 56 years; 79% no longer menstruating) enrolled in an open 3-month observational study were treated with the black cohosh extract, and the severity of climacteric symptoms was assessed on a visual analogue scale (VAS) and by a modified KM Index. VAS scores for hot flushes, profuse sweating, insomnia, nervousness/irritability and mood swings were included in the assessment. The percentage of hot flush symptoms classified as "very severe" decreased from a baseline of 51.9% to 16.3% after therapy. Conversely, the percentage of mild hot flushes increased from 16.2% initially to 59.9% under therapy. Mean values of the modified KM Index were 5.1 before and 2.9 after therapy. A beneficial effect was experienced by 73.8% of patients and 69.8% continued therapy after completing the study [Schmidt 2005].

A 3-month observational study carried out in Spain evaluated the effects of the black cohosh extract on the quality of life of 122 post-menopausal women who were experiencing climacteric symptoms; three sub-groups were assessed according to age range: 45-49 years (n = 35), 50-54 years (n = 54) and 55-59 years (n = 33). Before and after treatment each patient completed the Cervantes Scale, a 31-item self-reporting questionnaire designed to create a patient profile of health-related quality of life in four domains or categories: menopause and health (15 items, including vasomotor symptoms), psyche/mental (9 items), sexuality (4 items) and couple relationship (3 items). Compared to baseline the global quality of life score, and scores in the "menopause and health" and "psyche/mental" domains, had improved substantially across the entire population and in women of all three age groups at the end of 3 months of treatment. Improvement in the "sexuality" domain score was evident across the entire population but not in individual age ranges, while no changes were found in the "couple relationship" domain [Juliá Mollá 2009].

In an open observational study breast cancer patients undergoing tamoxifen therapy were also treated for climacteric complaints with the 40%-isopropanolic extract for 6 months, usually at the recommended dosage. Efficacy was assessed after 1, 3 and 6 months by means of the Menopause Rating Scale (MRS II; self-assessment scale) and tolerability was evaluated by each patient using a 5-point scale. Data from 47 patients (mean age 56 years; three-quarters postmenopausal) were available for intention-to-treat analysis. The initial tumour diagnosis dated back 8.6 months on average. All the women had previously undergone surgery, mainly breast-preserving; most had previously been treated with radiation therapy and hormones, and about half had undergone chemotherapy. On inclusion in the study metastases had already been diagnosed in 4 patients. Concomitant illnesses were documented in 29 women. Adjuvant treatment with tamoxifen had started on average 4 months after the first tumour diagnosis and 4 months prior to inclusion in the study. On commencement of therapy the dominant symptoms, of moderately severe intensity, were hot flushes and profuse sweating, followed by sleep disorders and physical and mental exhaustion. Mental symptoms (depressive moods, irritability and anxiety) were of mild intensity. MRS total scores of approximately two-thirds of the patients indicated "severe symptoms."

Most patients rated the efficacy of black cohosh as "good" to "satisfactory". The responder rate (very good, good or satisfactory efficacy) was 68.1% after 1 month and 70.2 % after 6 months. At the end of the black cohosh treatment the MRS total score had decreased substantially (from 17.6 to 13.6), as had subscores for "vegetative somatic complaints" and "mental complaints". The tolerability of the extract was rated as "very good" or "good" by 90% of the patients [Fischer 2006].

Women who reported at least 14 hot flushes per week were enrolled in an open, 4-week pilot study with the black cohosh extract; 21 patients (aged 38-80 years, mean 56 years) completed the study, of whom 13 had a history of breast cancer and 6 were also taking tamoxifen or raloxifene. At baseline (after keeping a diary in the previous week) the patients reported an average of 8.3 hot flushes per day. After 4 weeks the mean hot flush frequency had decreased by 50% to 4.2 per day, while the weekly hot flush score had decreased by 56%. The patients reported less trouble with sleeping, less fatigue and less abnormal sweating [Pockaj 2004].

Clinical studies performed with a 40%-isopropanolic dry extract of black cohosh (comparison between 39 and 127 mg of herbal drug/day)

In a randomized, double-blind study, 152 peri- and postmenopausal women outpatients (aged 42-60 years) with a KM Index score ≥ 20 (i.e. climacteric symptoms of at least moderate severity) were assigned to daily treatment for 24 weeks with the black cohosh extract at dose levels corresponding to either 39 mg (n = 76) or 127.3 mg (n = 76) of unprocessed drug; the study was not placebo-controlled. From the intention-to-treat group (n = 152) 123 patients completed the first 12 weeks and 116 completed 24 weeks.

Similar therapeutic effects were evident after 2 weeks in the two treatment groups; after 12 weeks the initial median KM Index scores of 30.5 (39 mg group) and 31.0 (127.3 mg group) had decreased to 8 and 7 respectively, and this was maintained to the end of the 6-month study period. The number of responders (defined by a KM Index score < 15) after 3 months was 70% in the 39 mg group and 72% in the 127.3 mg group. No significant difference in results was evident between the two groups from intention-to-treat or per-protocol analysis, indicating that a daily dose corresponding to 39 mg of unprocessed drug was sufficient. Self-Rating Depression Scale (SDS) scores supported the KM Index scores, reflecting an improvement in the state of menopausal depression during therapy in both groups without significant group differences [Liske 2002].

Clinical studies performed with a 58%-ethanolic dry extract of black cohosh (daily dose corresponding to 40 mg of herbal drug)

In a randomized, double-blind, placebo-controlled, three-armed multicentre study, post-menopausal women aged 40-60 with well-defined postmenopausal hormone levels and climacteric complaints were treated daily for 12 weeks with the black cohosh extract (n = 20) or 2 × 0.3 mg of conjugated oestrogens (CE, n = 22) or placebo (n = 20). Out of 97 patients initially randomized as intention-to-treat, almost one-third were subsequently found to have hormone levels not in accordance with the protocol and data on only 62 women were considered evaluable.

With regard to the primary efficacy criterion, the Menopause Rating Scale (MRS; 10 criteria, rated by the patients), superiority to placebo was evident after both the black cohosh extract ($p = 0.0506$) and CE ($p = 0.0513$). Although reductions in total scores did not quite reach significance due to a high placebo effect, evaluation of various combinations of MRS subscores revealed significant improvements (all $p<0.05$) in "major climacteric complaints" (4 criteria), "mental score" (4 criteria) and "atrophy"

(4 criteria) in the black cohosh group, in "hot flushes" (3 criteria) in the CE group, and in "somatic complaints" (5 criteria) in both the black cohosh and CE groups. Patients' diaries showed a decline in mean daily number of sweating episodes, reaching significance after 12 weeks in patients treated with black cohosh ($p<0.05$ vs. placebo) but not those treated with CE. Significant improvements in sleeping behaviour were also evident, the average number of nightly wake-up periods decreasing over 12 weeks in black cohosh- and CE-treated patients (both $p<0.05$ vs. placebo) [Wuttke 2003b, Wuttke 2006a].

Results from this study relating to effects on the endometrium and bone metabolism are summarized under Pharmacological studies in humans.

The effects of exercise training with and without black cohosh on bone mineral density (BMD) and 10-year coronary heart disease (CHD) risk were evaluated in 128 early postmenopausal women who were randomly assigned to one of three groups for a period of 12 months:

- Exercise group (n = 43). An initial 6-week conditioning period, then blocks of 6 weeks of high-intensity/high-impact exercise focussed primarily on bone strength, interspersed by blocks of 10 weeks of moderate exercise focussed on CHD parameters. Both blocks consisted of three weekly supervised group classes of 60 minutes.
- Exercise + black cohosh group (n = 43). The same exercise programme and the black cohosh extract - daily for 3 months, then discontinued for 3 months (as recommended by the manufacturer), with a further 3-month course thereafter and then abstinence.
- Control group (n = 42). A low-frequency and low-intensity exercise protocol focussed on well-being without causing physical adaptations; just 60 minutes of exercise weekly for 10 weeks, followed by 10 weeks of rest and so on.

Exercise group and control group participants received daily placebo tablets and all participants were given calcium and vitamin D supplements.

BMD at the lumbar spine decreased in the control group ($p<0.001$ compared to baseline) but was maintained in both exercise groups, which differed significantly from the control group (exercise group, $p = 0.001$; exercise + black cohosh group, $p = 0.005$) but not from each other. No significant differences in BMD between groups were evident at the femoral neck. The Framingham Risk Calculator (with scores based on age, total and HDL cholesterol, blood pressure, diabetes and smoking status) was used to calculate 10-year CHD risk, which increased significantly compared to baseline in the control group ($p = 0.007$) and in the exercise + black cohosh group ($p = 0.018$) but not in the exercise group ($p = 0.60$); however, no significant differences between groups were observed. As a secondary endpoint, menopausal complaints, assessed using the Menopause Rating Scale, significantly decreased in both exercise groups (exercise group, $p<0.001$; exercise + black cohosh group, $p = 0.003$) and increased marginally in the control group. The authors concluded that 12 months of fairly strenuous weekly exercise had favourably affected BMD and menopausal symptoms, and to a lesser extent 10-year CHD risk, and that under these conditions black cohosh did not enhance the positive effects [Bebenek 2010].

A randomized open study assessed the effects of black cohosh on hot flushes caused by tamoxifen (20 mg daily) in young premenopausal breast cancer survivors (aged 35-52 years) who had undergone surgery (lumpectomy or mastectomy), irradiation therapy and/or chemotherapy. Patients randomized to the "usual-care" group (n = 46) took tamoxifen only (for a period of 5 years), while those randomized to the intervention group (n = 90) commenced 12 months of treatment with the black cohosh extract 15 days before starting with tamoxifen. The number and severity of hot flushes was significantly reduced in the black cohosh group ($p<0.01$), with almost half of the patients (46.7%) free from hot flushes at the end of the study compared to none in the tamoxifen-only group. Severe hot flushes were reported by 24.4% of patients in the black cohosh group compared to 73.9% in the tamoxifen-only group [Hernández-Muñoz 2003].

In an open study primarily designed to investigate the safety of black cohosh, 400 postmenopausal women (aged 50-75 years) with symptoms including moderate to severe hot flushes were treated with the extract daily for 12 months. From self-assessment of their climacteric complaints using the Menopause Rating Scale II, baseline total scores decreased by about 50% over the course of treatment. The 4-week weighted score of hot flushes (number of hot flushes per day multiplied by a factor according to severity) decreased by 80.7% from baseline [Raus 2006].

In another open study, designed primarily to evaluate the effects of black cohosh on the liver, 100 healthy postmenopausal women (mean age 50 years), of whom 87 completed the study, were assigned to daily treatment with the extract for 12 months. Based on the participants' self-assessment, the prevalence, daily frequency and severity of hot flushes significantly decreased over the 12-month period of treatment ($p<0.001$ for each) [Nasr 2009].

Clinical studies performed with a 60%-ethanolic dry extract of black cohosh (DER 4.5-8.5:1)

In a randomized, double-blind, placebo-controlled study 180 women with menopausal complaints and a baseline KM Index score ≥ 20 were assigned to one of three daily treatments for 12 weeks: 13 mg of the black cohosh extract (as two tablets, each containing 6.5 mg; n = 60); one tablet containing 6.5 mg of the extract + one placebo tablet (n = 60); or two placebo tablets (n = 60). The most common complaints were hot flushes (89%), irritability and sleep disturbances (both 83%). KM Index scores, the primary efficacy variable, decreased significantly in both verum groups compared to placebo ($p<0.0001$ for 13 mg of extract, $p<0.001$ for 6.5 mg) and improvement in the 13 mg group was significantly superior to that in the 6.5 mg group ($p<0.01$). Responder rates (i.e. ≥ 50% decrease in the KM Index score) were found to be 63% in the 13 mg group, 38% in the 6.5 mg group and 7% in the placebo group. Quality of life scores, assessed on a visual analogue scale, improved in a comparable manner [Kaiser 2008].

A similar (or the same) extract was used in an earlier randomized, double-blind, placebo-controlled study, but only at the lower daily dose; 122 menopausal women (mean age 52 years) experiencing at least 3 hot flushes per day were treated with 6.5 mg of the extract (n = 81) or placebo (n = 41) daily for 12 weeks. There were two primary efficacy measures, the KM Index and a weekly weighted score of hot flushes, and secondary efficacy variables such as the Menopause Rating Scale. Primary efficacy analysis in the intention-to-treat population (median initial KM Index score < 20) did not demonstrate superiority of the black cohosh extract compared to placebo. However, in the subgroup of patients (n = 53) with a KM Index score ≥ 20 (i.e. with climacteric complaints of at least moderate intensity) improvements in this Index demonstrated significant superiority of black cohosh ($p<0.018$); reductions in scores of 47% and 21% were observed in the black cohosh (n = 35) and placebo (n = 18) groups respectively. The results for weekly weighted scores of hot flushes ($p<0.052$) and the Menopause Rating Scale ($p<0.009$) were in the same direction [Frei-Kleiner 2005].

Clinical study performed with a 70%-ethanolic dry extract of black cohosh (daily dose corresponding to 128 mg of herbal drug)

Women experiencing at least 35 menopausal vasomotor symptoms per week were assigned to one of four daily treatments for 12 months in a randomized, double-blind study: 128 mg of the 70%-ethanolic black cohosh dry extract, standardized to 7.27 mg of triterpene glycosides (n = 22), or 398 mg of a 70%-ethanolic dry extract of red clover (n = 22), or 0.625 mg of conjugated equine oestrogens + 2.5 mg of medroxyprogesterone acetate (CEE/MPA) as a positive control (n = 23), or placebo (n = 22). The women maintained diaries throughout the study, each day recording the number of vasomotor symptoms (hot flushes and night sweats) as well as the intensity (mild, moderate or severe) of hot flushes. Over the 12-month intervention period the average number of vasomotor symptoms decreased across all groups: black cohosh group, 34% reduction; red clover, 57%; CEE/MPA, 94%; placebo, 63%. There were no statistically significant differences in the number of vasomotor symptoms per week or hot flushes alone between placebo and black cohosh (or red clover) groups after 3, 6, 9 or 12 months. Vasomotor intensity was significantly higher in the black cohosh group than in the placebo group at the 6-month ($p = 0.008$) and 9-month time points ($p = 0.02$). The black cohosh extract was therefore ineffective in this study. In the CEE/MPA control group, relative to placebo, significant reductions in the number of vasomotor symptoms per week ($p<0.0001$ to $p = 0.0004$), vasomotor intensity ($p<0.001$ to $p<0.05$) and hot flushes per week ($p<0.0001$ to $p = 0.0001$) were recorded at all time points [Geller 2009].

Clinical study performed with a 70%-ethanolic dry extract of black cohosh (daily dose corresponding to 160 mg of herbal drug)

In a 12-month double-blind study 351 peri- and postmenopausal women aged 45-55 years were randomly assigned to one of five daily treatments: placebo (n = 84); a 70%-ethanolic extract of black cohosh (corresponding to 160 mg of crude drug; n = 80); a different black cohosh extract (corresponding to 200 mg of crude drug) in combination with eight other herbal ingredients (n = 76); the same herbal combination plus counselling to ensure increased consumption of dietary soya (n = 79); or conjugated equine oestrogens (0.625 mg daily, n = 32) with additional medroxyprogesterone acetate 2.5 mg for those women with an intact uterus (n = 29) [Note: Following premature ending of the Women's Health Initiative study in 2002 (due to concerns about the safety of HRT) participants in this arm were given the option of finding out if they had been assigned to hormone therapy; 16 were unblinded and 1 discontinued use of the study drug, but all remained enrolled]. Women with and without hysterectomy (without bilateral ovariectomy) and at least two vasomotor symptoms (hot flushes and/or night sweats) per day over 2 weeks were included.

The frequency and intensity of vasomotor symptoms were self-assessed and symptoms were recorded at baseline and after 3, 6 and 12 months. Additionally, the Wiklund Menopause Symptom Scale (rating the severity of 13 menopausal symptoms) was used, particularly the mean Wiklund Vasomotor Symptom subscale. At baseline the average number of vasomotor symptoms per day was 6.5 and the average intensity (mild, moderate or severe on a scale of 1 to 3) was 1.8. Of 183 women in menopausal transition at baseline 79 experienced no menstruation during the study. The primary outcome parameters, frequency and intensity of vasomotor symptoms and the Wiklund Vasomotor Symptom subscale score, decreased between baseline and 3 months in all groups. However, differences between any of the herbal groups and placebo were not significant at 3, 6 or 12 months. In contrast, the number of vasomotor symptoms per day and Wiklund Vasomotor Symptom subscale scores decreased significantly (both $p<0.001$ compared to placebo) in HRT-treated patients over the study period [Newton 2006].

Clinical studies performed with extracts not fully defined in the respective papers

In a randomized, double-blind, placebo-controlled cross-over study 132 patients aged 32-76 (64% with a history of breast cancer) who had experienced more than 14 hot flushes per week for at least one month were randomly assigned to daily treatment for 4 weeks with either a black cohosh extract (corresponding to 2 × 20 mg of crude drug; extraction solvent not stated) or placebo, followed by a further 4-week period on the alternative treatment. As co-medication 44% of the patients continued taking tamoxifen, 1% raloxifene and 11% an aromatase inhibitor; the co-medication of 8% was unknown and 36% took no other medication. Data from 116 patients were analysed. Each patient kept a daily hot flush diary (frequency and severity) and a weekly symptom experience diary (rating various symptoms and impressions from 0 to 10), and the Greene Climacteric Scale was completed at baseline and after 4 weeks of both treatments. The primary endpoint was the difference in average hot flush scores (a combination of average daily hot flush frequency and severity) between the baseline week and the last study week of the first treatment period.

Patients on black cohosh reported a mean decrease of 15% in hot flush scores during the fourth treatment week, compared to a 31% decrease for patients on placebo. Thus no significant difference in efficacy between black cohosh and placebo treatment was evident from primary endpoint results after 4 weeks ($p = 0.10$), and cross-over analysis did not suggest any benefit for black cohosh ($p = 0.98$). Furthermore, there were no differences in any of the symptoms evaluated in symptom experience diaries or in overall quality of life, and no significant decrease in either arm for any parameter of the Greene Climacteric Scale [Pockaj 2006].

Patients who had previously received chemotherapy and radiation therapy for breast cancer and were experiencing daily hot flushes participated in a randomized, double-blind, placebo-controlled study to assess the effect of black cohosh (2 tablets of a commercial product daily for 2 months; no further details given) on the frequency and intensity of hot flushes on a 1 to 3 scale. Some patients also used tamoxifen concomitantly for the management of breast cancer. Of the 85 study participants, 42 (of whom 29 used tamoxifen) were assigned to treatment with black cohosh and 43 (of whom 30 used tamoxifen) were assigned to placebo; 69 patients completed the study. Both black cohosh and placebo groups reported a decline in the frequency (about 27% overall) and intensity of hot flushes during the study, but differences between groups were not significant. Both groups reported improvements in seven menopausal symptoms (heart palpitations, excessive sweating, headaches, poor sleep, depression and irritability or nervousness) during the study, but only sweating was significantly reduced in the black cohosh group compared to the placebo group ($p = 0.04$). Small changes in serum levels of follicle-stimulating hormone and luteinizing hormone also did not differ between groups [Jacobson 2001].

In a randomized study 120 women (average age 53 years) with post-menopausal symptoms were assigned to daily treatment for 6 months with either a black cohosh extract (40 mg, extraction solvent not stated, n = 60) or fluoxetine (20 mg, n = 60), with interim assessments after 1, 2 and 3 months. The daily number and severity (graded from 0 to 3) of hot flushes and night sweats were recorded in diaries to calculate monthly scores (number × severity to obtain a daily score, all daily scores added together to

yield the score for the month). A modified KM Index (including vaginal dryness), Beck's Depression Scale and a quality of life questionnaire (RAND-36) were also used in assessments at baseline and after 3 months of treatment.

KM Index and Beck's Depression Scale scores decreased significantly within 3 months in both groups ($p<0.001$ compared to baseline) with significantly greater reduction in KM Index score in the black cohosh group ($p = 0.02$) and in Beck's Depression Scale score in the fluoxetine group ($p = 0.01$). Compared to month 1 scores, month 6 hot flush scores and night sweat scores had decreased significantly in both groups ($p<0.001$ for both scores in both groups), but to a significantly greater extent in the black cohosh group ($p<0.001$ for both scores); by the end of 6 months of therapy the hot flush score had decreased by 85% in the black cohosh group compared to 62% in the fluoxetine group. Quality of life improved in all parameters except pain in both treatment groups [Oktem 2007].

In an open study, 61 post-menopausal women (aged 36-62 years) with daily symptoms, natural or following surgery, took a black cohosh extract (2 × 40 mg capsules daily, each standardized to 1 mg of 23-*epi*-26-deoxyactein; extraction solvent not stated) for 12 weeks followed by a 12-week wash-out phase (a total of 24 weeks of assessment); 48 subjects were available for assessment after 4 weeks, 46 after 12 weeks and 45 after 24 weeks. Menopausal symptoms, assessed using the KM Index, improved in 83% of the women by week 4 (at least 1 point reduction in KM Index score) and at 12 weeks at least 21% of patients had a 50% reduction in their KM Index score. During the wash-out phase KM Index scores increased by at least 1 point in 73% of the patients [Ruhlen 2007].

In another open study, 50 postmenopausal women were treated daily for 6 months with a black cohosh extract (type and amount not stated). An excellent response was reported in subjective complaints assessed by the KM Index and Hamilton Anxiety Scale; only 10% of patients had no relevant improvement after 3 months. Endometrial thickness (measured by endovaginal ultrasound) remained unchanged after 6 months [Georgiev 1997].

Patients with a DSM-IV diagnosis of anxiety disorder due to menopause were randomized to treatment with 2-4 × 32 mg of a black cohosh extract (5.6% triterpene glycosides, extraction solvent not stated; n = 15) or placebo (n = 13) daily for up to 12 weeks in a double-blind, placebo-controlled study. No significant anxiolytic effect of black cohosh was evident from the primary outcome measure, Hamilton Anxiety Rating Scale (HAM-A) scores ($p = 0.29$), or the proportion of subjects with a reduction at least 50% in baseline HAM-A scores by the end of the study period ($p = 0.79$). The authors noted that the extremely small sample size of this preliminary study limited their ability to identify clinically meaningful differences between groups [Amsterdam 2009].

Clinical studies performed with a 40%-isopropanolic dry extract of black cohosh (8 mg/day)

The corresponding amounts of herbal drug were not stated in the respective papers, but were within the range of 40-140 mg [Boblitz 2000]

In a randomized, double-blind, three-armed study, women aged 46-58 years received one of the following treatments daily for 12 weeks: 8 mg of the black cohosh extract (n = 30) or 0.625 mg of conjugated oestrogens (n = 30) or placebo (n = 20). The patients suffered from menopausal complaints such as hot flushes, sweating, palpitations, depressed mood and sleep disorders; they also had vaginal complaints due to oestrogen deficiency. Effects on climacteric symptoms were assessed by the KM Index and Hamilton Anxiety Scale (HAMA). Compared to placebo the extract produced a significant decrease in KM Index scores (mean value from 34 to 14; $p<0.001$) and the HAMA ($p<0.001$). Vaginal cytology parameters also improved significantly ($p<0.001$). The extract significantly increased the degree of proliferation of the vaginal epithelium from 2-3 to 3-4 on the Schmitt scale for vaginal cytology ($p<0.01$ compared to placebo) [Stoll 1987]. This study has been described as questionable because of low methodological quality and, in finding no difference between placebo and 0.625 mg of oestrogen, a result that contradicts a large body of data [Borelli 2008a].

In an open, randomized, comparative study 60 women under 40 years of age who had undergone hysterectomy but retained at least one intact ovary and complained of climacteric symptoms were treated daily for 24 weeks with 1 mg of oestriol (n = 15) or 1.25 mg of conjugated oestrogens (n = 15) or an oestrogen-progesterone sequence preparation (n = 15) or 8 mg of the black cohosh extract (n = 15). Using a modified KM Index for assessment at 4, 8, 12 and 24 weeks, statistically significant decreases in climacteric symptoms were observed in all treatment groups ($p<0.01$). Conjugated oestrogens and the oestrogen-progesterone combination appeared to be slightly superior but differences between the groups were not statistically significant [Lehmann-Willenbrock 1988].

In another open study, 50 women with climacteric symptoms, who had previously been treated every 4-6 weeks with intramuscular injections of a combination of oestradiol valerate 4 mg and prasterone nantate 200 mg, were treated with the black cohosh extract for 6 months. During this time 28 patients (56%) required no further injections, 21 patients (44%) required one injection and 1 patient required two injections. The KM Index decreased on average from 17.6 to 9.2 ($p<0.001$) [Pethö 1987].

Clinical studies performed with a 60%-ethanolic dry extract of black cohosh (80 drops/day)

The corresponding amounts of herbal drug were not stated in the respective papers, but were within the range of 40-140 mg [Boblitz 2000]

In an open, randomized, three-armed study 60 women (aged 45-60 years) with climacteric symptoms received the black cohosh extract (n = 20) or 0.6 mg of conjugated oestrogens (n = 20) or 2 mg of diazepam (n = 20) daily for 12 weeks. All three forms of treatment led to reductions in a modified KM Index (which included hot flushes, nocturnal sweating, nervousness, headache and palpitations), the Hamilton Anxiety Scale and a Self-assessment Depression Scale. Conjugated oestrogens and (in contrast to other studies) the black cohosh extract showed a trend towards oestrogenic stimulation, with increased proliferation of the vaginal epithelium as shown by increases in karyopyknosis and eosinophil indices [Warnecke 1985].

In an open study in 50 women aged 45-60 years with climacteric complaints (mainly neurovegetative), the black cohosh extract reduced symptoms assessed as moderate by the KM Index to "requiring no therapy" after 12 weeks ($p<0.001$) [Vorberg 1984].

In another open study, in 36 women aged 45-62 years with climacteric symptoms, treatment with the black cohosh extract for 12 weeks led to a significant average decrease in KM Index scores compared to initial values ($p<0.001$) [Daiber 1983].

In an open, multicentre, drug-monitoring study of 629 patients, menopausal symptoms such as hot flushes, profuse sweating, headache, vertigo, nervousness and depression improved in over 80% of cases after 6-8 weeks of treatment with the black cohosh extract [Stolze 1982].

Pre-1970 clinical studies
From 1957 to 1964 a number of case reports and uncontrolled studies were published describing the successful treatment of numerous women with climacteric symptoms or menstrual disorders with black cohosh extracts [Kesselkaul 1957, Schotten 1958, Földes 1959, Stefan 1959, Stiehler 1959, Brücker 1960, Heizer 1960, Starfinger 1960, Görlich 1962, Langfritz 1962, Schildge 1964].

Clinical reviews
In a systematic review of the clinical efficacy of black cohosh in the treatment of menopausal symptoms, published in 2002, only randomized, blind and controlled studies were considered. Four studies involving a total of 226 women met the inclusion criteria [Warnecke 1985, Stoll 1987, Lehmann-Willenbrock 1988, Jacobson 2001] and two were placebo-controlled [Stoll 1987, Jacobson 2001]. The authors concluded that, in spite of plausible mechanisms of action, the clinical efficacy of black cohosh for the treatment of menopausal symptoms had not been convincingly demonstrated [Borrelli 2002].

An update by the same authors in 2008 evaluated more recent evidence from randomized, double-blind studies; only mono-preparations of black cohosh in comparison with placebo or a standard drug were considered and studies involving medically (drug)-induced menopause or women with bilateral hysterectomy were excluded. Six studies involving a total of 1112 peri- and post-menopausal women met the inclusion criteria [Osmers 2005, Bai 2007, Wuttke 2003b + Wuttke 2006a, Frei-Kleiner 2005, Newton 2006, Stoll 1987]. The authors considered that the efficacy of black cohosh in reducing menopausal symptoms was still not supported by fully conclusive evidence and further investigations are desirable [Borrelli 2008a].

Another systematic review of black cohosh in the treatment of menopausal symptoms, based on searches up to November 2007, considered 12 randomized studies using mono-preparations:

- Placebo-controlled studies [Osmers 2005, Wuttke 2003b, Frei-Kleiner 2005, Newton 2006, Pockaj 2006, Jacobson 2001, Stoll 1987].
- Studies comparing black cohosh with reference medications of known therapeutic efficacy: tibolone [Bai 2007], fluoxetine [Oktem 2007] or oestrogen therapy [Nappi 2005, Lehmann-Willenbrock 1988, Warnecke 1985].

Two out of seven placebo-controlled studies [Osmers 2005, Stoll 1987] and all five comparisons with reference medications were found to suggest significant therapeutic benefit from black cohosh. The authors concluded that black cohosh alone may not have a meaningful effect on menopausal symptoms in most cases [Palacio 2009].

Clinical review with meta-analysis
Four randomized placebo-controlled studies [Osmers 2005, Wuttke 2003b, Frei-Kleiner 2005, Newton 2006] were included in a systematic review of the efficacy of black cohosh mono-preparations for the treatment of menopausal symptoms in peri- and/or postmenopausal women with no history of breast cancer. In three of the studies [Osmers 2005, Wuttke 2003, Frei-Kleiner 2005] black cohosh was found to be efficacious in reducing the frequency of vasomotor symptoms, but no significant improvement compared to placebo was evident in the fourth study [Newton 2006].

Only two of the studies [Frei-Kleiner 2005, Newton 2006] afforded data suitable for meta-analysis. From the pooled data, the combined estimate of rate difference for improvement of vasomotor symptoms (defined as the difference between black cohosh and placebo groups with respect to the change in proportion of subjects with vasomotor symptoms between baseline and 12 weeks) was calculated as 11%. Although this was only moderately positive, one of the two studies on which the calculation was based had not shown superiority over placebo [Newton 2006], and a further relevant and highly positive study [Kaiser 2008] was not taken into account [Shams 2010].

Pharmacokinetic properties
Single doses of 32, 64 or 128 mg of a 75%-ethanolic black cohosh extract, containing 1.4, 2.8 or 5.6 mg respectively of 23-*epi*-26-deoxyactein, were administered orally to 15 healthy menopausal women, assigned to one of three dosage groups with 5 women per group. Blood samples and urine were collected over a period of 24 hours from administration. In all three groups the serum concentration of 23-*epi*-26-deoxyactein increased rapidly during the first hour, reaching a maximum after 2.0-2.9 hours; the serum half-life was 2.1-3.0 hours and the area under the curve increased linearly with dosage; less than 0.01% was recovered in urine. Since only small amounts of the ingested 23-*epi*-26-deoxyactein were detected intact in blood or urine and no metabolites were detected, it appeared likely that this glycoside undergoes degradation in the stomach; *in vitro* tests indicated a half-life of 80 minutes in simulated gastric fluid [van Breemen 2010].

In rats treated orally with actein at 35.7 mg/kg body weight the serum level of actein reached a peak of 2395 ng/litre at 6 hours then declined to 102 ng/litre within 24 hours; in urine collected for the first 24 hours the concentration of actein was 777 ng/litre [Einbond 2009].

Preclinical safety data

Chronic toxicity
A 40%-isopropanolic dry extract of black cohosh, administered to rats for 6 months as a daily dose equivalent to the unprocessed drug at 535.5 mg/kg body weight (approximately 700 times the human therapeutic dose), produced no outward signs of toxicity or histopathological changes [Boblitz 2000].

Mutagenicity
In the Ames test a 40% V/V-isopropanolic dry extract of black cohosh revealed no mutagenic potential at up to the equivalent of 30.3 mg of unprocessed drug per plate [Boblitz 2000]. A 60% V/V-ethanolic dry extract of black cohosh also gave a negative result in the Ames test [UKPAR].

Acute toxicity of actein
Minimum lethal single doses of actein were determined [Genazzani 1962] as:
Mouse, intraperitoneal: > 500 mg/kg
Rat, oral: > 1000 mg/kg
Rabbit, intravenous: > 70 mg/kg

Subchronic toxicity of actein
Minimal lethal doses of actein administered daily for 30 days were determined [Genazzani 1962] as:
Mouse, intraperitoneal: > 10 mg/kg
Rabbit, oral: > 6 mg/kg

Clinical safety data
Doses of up to 200 mg of black cohosh or corresponding amounts of extracts have been used without apparent adverse effects [Liske 2002, Cimicifuga-UK GSL 1990].

Adverse events reported in clinical studies
In two 12-week randomized studies using a 60%-ethanolic dry extract (4.5-8.5:1) of black cohosh no significant differences were reported between verum and placebo groups in the prevalence or intensity of adverse events. In the first study the frequencies were 17/83 patients (20%) in the black cohosh group (6.5 mg of extract per day) and 10/44 (23%) in the placebo group [Frei-

Kleiner 2005]. The frequencies in the second study, 4/60 (7%) in both 6.5 mg/day and 13 mg/day groups, and 6/60 (10%) in the placebo group, bore no relationship to dosage [Kaiser 2008]. In another study the proportion of patients with adverse effects judged to have at least a "possible" causal relationship with the study medication was assessed as 6/153 (3.9%) in the black cohosh group and 7/151 (4.6%) in the placebo group [Osmers 2005].

Adverse events were reported in every arm of a study in which patients were treated for 12 months with HRT, black cohosh or placebo; none were severe in the black cohosh arm. Menstrual disorders were reported more frequently in the HRT group than in the placebo group ($p<0.001$; HRT, 59% of patients; placebo, 20%; black cohosh, 13%), as was breast discomfort ($p = 0.04$; HRT, 16% of patients; placebo, 4%; black cohosh, 0%) [Newton 2006]. In the same study black cohosh was found to have no effects on vaginal epithelium, the endometrium or reproductive hormones such as oestradiol, FSH, LH and SHBG [Reed 2008].

In another 12-month study, no significant differences were evident between menopausal women who took 128 mg of a 70%-ethanolic black cohosh dry extract daily and those who took placebo with respect to adverse events (none serious) or any of a wide range of safety parameters tested, including breast and endometrial screening, liver function, blood count and lipid profile [Geller 2009].

No significant differences in adverse effects between black cohosh groups and placebo groups were found in a systematic review of nine randomized, placebo-controlled studies, in four of which mono-preparations of black cohosh were used [Osmers 2005, Wuttke 2003b, Frei-Kleiner 2005, Newton 2006]; the other five involved black cohosh combined with other active ingredients [Shams 2010].

During 6 months of treatment with a black cohosh extract (40 mg/day) or fluoxetine (20 mg/day) all reported adverse events were mild, but the frequency was significantly lower in the black cohosh group (7/40 patients) than in the fluoxetine group (13/40) ($p<0.001$) [Oktem 2007].

In an open clinical study 19/61 (31%) of the patients, who took 2 × 40 mg of a black cohosh extract daily for 6 months, reported adverse events: 12 gastrointestinal, 5 reproductive (vaginal dryness, nipple tenderness), 4 headaches, 1 of dysphagia and 1 of fatigue. None were reported to be serious but they led to 5 dropouts [Ruhlen 2007].

A retrospective case-control study carried out in a USA-based population of 949 breast cancer cases and 1,524 controls evaluated whether the use of herbal preparations to manage menopausal symptoms was associated with breast cancer risk. The authors concluded that the use of black cohosh had a significant breast cancer protective effect (adjusted odds ratio 0.39, 95% CI: 0.22-0.70). This association was similar among women who reported use of either black cohosh or specifically a 40%-isopropanolic dry extract [Rebbeck 2007].

In a German case-control study, associations between patterns of use of herbal preparations and the incidence of breast cancer were investigated in 10,121 postmenopausal women (3,464 cases and 6,657 controls). Information was collected in face-to-face interviews supported by a list of brand names and the preparations evaluated contained black cohosh, St. John's wort, "phytoestrogens" (red clover or soy isoflavones), agnus castus or certain other herbal active ingredients. In the 9.9% of these women who had ever used a herbal preparation the risk of invasive breast cancer was found to decrease by approximately 26% overall, and by 4% per year of use ($p = 0.03$), irrespective of a healthy lifestyle (physical activity and diet) or the histological type and receptor status of the tumour. Risk estimates did not differ significantly between different types of herbal active ingredients. For a 40%-isopropanolic dry extract of black cohosh (in a mono-preparation or a combination with St. John's wort) the inverse association with invasive breast cancer was found to have an odds ratio of 0.80 (95% CI: 0.63-1.00); for other black cohosh preparations the odds ratio was 0.96 (95% CI: 0.64-1.45). These findings supported the hypothesis of a protective effect of black cohosh against breast cancer in postmenopausal women [Obi 2009].

The clinical safety of black cohosh was investigated in an open study by determining its effects on mammographic breast tissue density and, from collection of breast cells by fine needle aspiration biopsy and assessment using the Ki-67 marker, on breast cell proliferation. The baseline status of 74 postmenopausal women with menopausal symptoms was compared by blinded observers with their status after 6 months of treatment with a 40%-isopropanolic extract (corresponding to 40 mg/day of black cohosh). None of the mammography results indicated a change in breast tissue density over the period of treatment and there was no increase in breast cell proliferation. No change was observed in mean endometrial thickness, and laboratory parameters and vital functions remained normal. Adverse events, possibly related to the treatment, were reported by 12 women (16%), but none were severe [Linden Hirschberg 2007].

Anonymous data relating to breast cancer patients (including those with oestrogen receptor-positive tumours) who had been treated between 1992 and 2003 in 1,511 medical practices in Germany were evaluated in a retrospective cohort study; the mean age at diagnosis was 61.4 years. The main endpoint was disease-free survival following a diagnosis of breast cancer in relation to the use of an isopropanolic black cohosh extract, alone or in combination with a St. John's Wort extract. A total of 18,861 women were included in the analysis, of whom 1,102 were categorized as black cohosh users and 17,759 served as a control group. There was a significant association between black cohosh and tamoxifen use with tamoxifen patients 67% more likely to have been placed on black cohosh than their non-tamoxifen counterparts ($p<0.0001$).

The mean observation period between diagnosis and last database entry was 3.6 years in the control group but longer, 4.6 years, for black cohosh users. The rate of recurrence in the control group (3,148 out of 17,759, i.e. 17.7%) was higher than in black cohosh patients (113 out of 1,102, i.e. 10.3%). In the control group 14% of women developed a recurrence within 2 years of first diagnosis while this proportion was reached in the black cohosh group only after 6.5 years. The data showed that black cohosh was not associated with an increase in risk of recurrence but associated with prolongation of disease-free survival [Henneicke-von Zepelin 2007].

The endometrial safety of a 58%-ethanolic black cohosh extract, taken for 12 months at a daily dose corresponding to 2 × 20 mg of herbal drug, was assessed from biopsy samples of endometrial tissue in an open prospective study involving 400 postmenopausal women (aged 50-75 years) with symptoms including moderate to severe hot flushes. No cases of endometrial hyperplasia or more serious adverse endometrial outcomes occurred and endometrial thickness, measured by endovaginal ultrasonography, did not increase compared to baseline. Mammograms from 138 patients were available for evaluation and showed no increase in breast density, except in the case of one woman found to have breast cancer unrelated to the medication. No clinically relevant changes in hormone levels

were observed during the study. From a total of 752 recorded adverse events 318 (42%) were assessed as possibly and 8 (1%) as probably related to the black cohosh medication, the majority (295) of these being due to increased serum lipids. The intensity of adverse events was mild in about 88% of cases, moderate in 10.5% and severe in 1.9%. None of eight adverse events assessed as serious were considered to have a causal relationship with the medication; four resulted from an accident and the others included a planned cholecystectomy, acute bronchitis and surgery [Raus 2006].

In a 3-month surveillance study involving 502 women with menopausal complaints the tolerability of black cohosh was generally assessed as very good [Schmidt 2005] and in a subsequent 6-month observational study of over 6000 women more than 90% of physicians and patients rated the tolerability as excellent or good [Briese 2007].

Effects on the liver

The European Medicines Agency (EMA, formerly EMEA) assessed all available case reports (up to 2007) associating hepatotoxicity and black cohosh with regarding to causality. In 26 of the 43 cases there was insufficient documentation to support a causal relationship between black cohosh use and hepatotoxicity. The association was deemed unrelated in 5 cases and unlikely in 7 cases, leaving only 5 cases classified as having "possible" or "probable" causality. Based on these findings, the HMPC recommended the following advice: "Patients should stop taking Cimicifugae racemosae rhizoma (black cohosh, root) and consult their doctor immediately if they develop signs and symptoms suggestive of liver injury (tiredness, loss of appetite, yellowing of the skin and eyes or severe upper stomach pain with nausea and vomiting or dark urine)" [EMEA 2007].

Four cases of hepatotoxicity classified in the EMEA's assessment of June 2006 as having "possible" or "probable" causality with the use of black cohosh were re-evaluated using the qualitative and quantitative causality assessment of the updated system of the Council for International Organizations of Medical Sciences (CIOMS); the fifth case was reported at a later date and appeared in the EMEA's updated assessment (Rev 1) of May 2007. Due to incomplete data, one of the four cases was not assessable. Of the remaining three, one patient had a favourable course under continued steroid therapy and the final diagnosis was autoimmune hepatitis; the other two patients required liver transplants following final diagnoses of herpetic hepatitis. Using a causality assessment in the form of a diagnostic algorithm it was concluded that there was no evidence for a causal relationship between treatment with black cohosh and observed liver disease in the four patients.

Even in the five possible or probable cases it was found that the products in question, the co-medications and the adverse reactions were not precisely defined in the original reports. Duplicated cases could not easily be identified because information such as duration of intake, dosage, co-medication or medical history was often lacking or contradictory [Teschke 2009a, Teschke 2009b, Hudson 2007].

The Expert Committee of the US Pharmacopeia reviewed and analysed information relating to black cohosh from human clinical case reports, adverse event reports, animal pharmacological and toxicological data, historical use, regulatory status and contemporaneous extent of use. Reports were obtained from various sources including the EMEA, Health Canada, the Australian Therapeutic Goods Administration and the US FDA. Case reports associating liver damage with the use of black cohosh were evaluated using the Naranjo causality algorithm scale; 30 non-duplicate cases were assigned "possible" causality, but none were assigned probable or certain causality [Mahady 2008].

The position regarding black cohosh and suspected hepatoxicity has been summarized in a 2010 review [Teschke 2010]. While the original case reports of hepatotoxicity were generally of poor quality, with major inconsistencies and confounding variables, and no definite causal relationship was established [Teschke 2009a, Teschke 2009b, Teschke 2010], further case reports have appeared [Mahady 2009, Mahady 2010, Guzman 2009, Vannacci 2009, Pierard 2009]. From a consumer protection standpoint some regulatory authorities (in the European Union, the USA and Australia, for example) have taken the view that a safety signal is discernible and hence black cohosh products should be labelled to include a cautionary statement [EMEA 2007, Mahady 2008, Mahady 2009, Mahady 2010].

To evaluate the effects of black cohosh on liver function 100 healthy postmenopausal women (mean age 50 years), of whom 87 completed the study, were treated daily for 12 months with a 58%-ethanolic extract (corresponding to 40 mg of dried rhizome). Women with abnormal liver function were excluded and menopausal state was confirmed from follicle-stimulating hormone (FSH) levels. From assessments at baseline and after 12 months no significant changes were observed over the treatment period in hepatic blood flow or liver function tests (prothrombin time and concentration, serum albumin, bilirubin, γ-glutamyltransferase, alkaline phosphatase, alanine aminotransferase and aspartate aminotransferase), nor in body weight or blood pressure [Nasr 2009].

Over a 10-year period a black cohosh extract (2.5% actein, extraction solvent not stated) at high daily doses of 500 mg or 1000 mg, alone or in combination with other herbal ingredients, was prescribed to 798 women with menopause-related complaints by an Italian clinic of natural medicine without any reported adverse effects. In response to a public statement (2006) by the EMEA concerning a possible link between black cohosh and cases of hepatotoxicity, 158 patients who had taken the extract continuously for at least 12 months were identified and contacted, and 107 menopausal women were subsequently followed up by telephone (33/107) or by physical examination including evaluation of blood samples and parameters of liver function (74/107). No sign of hepatic disease, or worsening of already altered but stable liver function parameters, was detected in any of the 107 patients [Firenzuoli 2008].

Following the administration of single doses of 32, 64 or 128 mg of a 75%-ethanolic black cohosh extract to groups of 5 healthy menopausal women in a pharmacokinetic study no serum markers of liver function were found to have changed significantly from baseline within 12 hours [van Breemen 2010].

Interactions

In an open-label study randomized with respect to both medication and sequence 16 healthy young volunteers received, on separate occasions followed by 30-day wash-out periods: a black cohosh extract (2 × 20 mg/day; 14 days), a milk thistle extract (3 × 300 mg/day; 14 days) and, as positive controls for transport protein P-gp induction and inhibition respectively, rifampin (2 × 300 mg/day; 7 days) and clarithromycin (2 × 500 mg/day; 7 days). Digoxin (0.4 mg) was administered orally 24 hours before the start and on the last day of each treatment period, and serum digoxin concentrations were monitored over the next 24 hours. The black cohosh and milk thistle preparations had no significant effects on digoxin pharmacokinetics and hence appeared to pose no clinically significant risk for P-gp-mediated interactions [Gurley 2006a].

In a further study of similar design, the effects of black cohosh and milk thistle extracts on cytochrome P450 CYP3A enzyme activity were investigated in 19 healthy young volunteers. They

were randomly assigned to receive, on separate occasions followed by wash-out periods, a black cohosh extract (2 × 40 mg/day; 14 days), a milk thistle extract (3 × 300 mg/day; 14 days) and, as positive controls for CYP3A induction and inhibition respectively, rifampin (2 × 300 mg/day; 7 days) and clarithromycin (2 × 500 mg/day; 7 days). Midazolam (8 mg) was administered orally 24 hours before the start and on the last day of each treatment period, and serum midazolam and 1-hydroxymidazolam concentrations were monitored for 6 hours thereafter. In contrast to the marked effects caused by rifampin and clarithromycin, midazolam pharmacokinetics were unaffected by black cohosh and milk thistle, which appeared to have no clinically relevant effect on CYP3A activity [Gurley 2006b].

Other studies, of similar design and carried out by the same research group, have shown that black cohosh has no clinically relevant effects on human CYP1A2, CYP2E1, CYP3A4/5 [Gurley 2005] and CYP2D6 [Gurley 2008] enzymes.

Other human safety data
The authors of a review suggested that black cohosh should be used with caution during pregnancy, particularly during the first trimester where its purported labour-inducing effects could be of concern, and during lactation [Dugoua 2006].

Patients with unexplained infertility (n =119) were randomly divided into two groups. Both groups received clomiphene citrate (an ovulation-inducer) at 150 mg/day on days 3-7 and one group also received a black cohosh extract (corresponding to 120 mg/day of herbal drug) on days 1-12. When a leading follicle attained a diameter > 17 mm and serum oestradiol exceeded 200 pg/ml human chorionic gonadotrophin (HCG) was injected and scheduled intercourse recommended. The pregnancy rate was significantly higher in the black cohosh group ($p<0.01$). No safety issues were reported [Shahin 2008].

Safety reviews
Data from 13 clinical studies, 3 postmarketing surveillance studies, 4 series of cases and 8 single case reports, evaluated to assess the evidence for or against the safety of black cohosh, suggested that black cohosh is safe to use at the recommended dose. Attribution of causality of severe adverse events in case reports proved problematic and required further investigation [Borrelli 2008b].

A critical evaluation of the safety of black cohosh concluded that human clinical studies, postmarketing surveillance studies and uncontrolled reports involving over 2,800 patients demonstrated a favourable safety profile with a low incidence of adverse events (5.4%). Of the reported adverse events, 97% were minor and did not result in discontinuation of therapy. No severe adverse events were attributed to black cohosh [Low Dog 2003].

A systematic review of data from clinical studies and also from spontaneous reporting programmes of the World Health Organization and national regulatory bodies suggested that adverse events arising from the use of black cohosh are rare, mild and reversible, the most common being gastrointestinal upsets and rashes. It was concluded that, although definitive evidence is not available, black cohosh seems to be a safe herbal medicine [Huntley 2003].

In another review the author concluded that clinical studies and case reports have demonstrated good tolerance of, and low risk of side effects from, ethanolic and isopropanolic extracts of black cohosh [Foster 1999].

From a systematic review of 5 clinical studies in which breast cancer patients took black cohosh extracts for the treatment of hot flushes and other menopausal symptoms, as well as evidence from 21 preclinical studies relating to black cohosh and cancer, it was concluded that the use of black cohosh appears to be safe in breast cancer patients [Walji 2007].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

COLAE SEMEN

2014

Cola

DEFINITION

Cola consists of the whole or fragmented dried seeds, freed from the testa, of *Cola nitida* (Vent.) Schott et Endl. (*C. vera* K. Schum.) and its varieties, as well as of *Cola acuminata* (P. Beauv.) Schott et Endl., (*Sterculia acuminata* P. Beauv.). It contains not less than 1.5 per cent of caffeine (M_r 194.2) (dried drug).

The material complies with the monograph of the European Pharmacopoeia [Cola].

CONSTITUENTS

The main constituents are purine alkaloids such as caffeine (approximately 2%) and small amounts of theobromine (0.02 to 0.08%) and theopylline. Other constituents are catechins, proanthocyanidins, tannins (5 to 10%), up to 45% starch, sugars, proteins and minerals [Weinges 1964; Weinges 1967; Balansard 1987; Morton 1992; Seitz 1992; Adeyeye 1994: Boudjeko 2009; Bruneton 1998; Wichtl 2002; Atawodi 2007; Niemenak 2008; Burdock 2009].

Fresh material contains caffeine-catechin-complexes (approximately 90% of the caffeine present) [Maillard 1988; Seitz 1992; Wichtl 2002].

Primary amines such as methylamine and secondary amines such as dimethylamine have also been determined in quantities of up to 100 ppm [Atawodi 1995]. Thiamine and other B-vitamins are also present [Heinrich 2004].

CLINICAL PARTICULARS

Therapeutic indications
For the treatment of short-term physical and/or mental exhaustion. In these indications, the efficacy is plausible on the basis of human experience and long-standing use [Kerharo 1969; Etkin 1981; Bradley 1992].

Posology and method of administration

Dosage

Adults and children above 12 years:
Dried drug: 2-6 g per day, divided into up to 3 doses [Bradley 1992; Seitz 1992].
Liquid extract (1:1 in 60% ethanol), 0.6-1.2 mL three times daily [Bradley 1992].

Method of administration
For oral administration.

Duration of administration
If symptoms persist or worsen, medical advice should be sought.

Contra-indications
Gastric or duodenal ulcers [Ibu 1986].

Special warnings and special precautions for use
The intake of cola should be restricted in individuals with hypertension and cardiac disorders, because of the caffeine content [Bradley 1992; Barnes 2007].

Interaction with other medicaments and other forms of interaction
Due to the caffeine content, concomitant intake of caffeine-containing drinks or psycho-analeptic medicines may cause a stronger caffeine effect.

Pregnancy and lactation
There is evidence of effects of cola consumption by women on the head and chest measurements of their new born infants [Abidoye 1990]. The product should not be used during pregnancy or lactation without medical advice.

E/S/C/O/P
MONOGRAPHS

Effects on ability to drive and use machines
None known.

Undesirable effects
Difficulties in falling asleep, excitation, nervousness. Gastrointestinal disturbances are possible [Atawodi 1995; Barnes 2007].

Overdose
Overdosage may result in enhanced effects as described under "Undesirable effects".

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments
An aqueous decaffeinated cola extract, containing approximately 40% oligomeric and polymeric procyanidins, showed oxygen radical scavenging activity as well as reduction of elastase liberation from polymorphonuclear neutrophils [Daels-Rakotoarison 2003].

In vivo experiments

Effects on locomotor activity
An experiment involving i.p. administration of an aqueous extract to mice resulted in no effect at the lower dose of 2.5 mg/kg b.w., yet significantly ($p<0.01$) increased locomotor activity at the medium dose of 5.0 mg/kg b.w. and slightly depressed locomotor activity at the highest dose of 10.0 mg/kg b.w. [Ajarem 1990].

Oral administration of a dried aqueous extract (1:2) at doses of 400 mg and 800 mg/kg b.w. resulted in significantly enhanced exploratory activity of rats during the first day only ($p<0.05$). The effect was similar but weaker than that following administration of caffeine at 15 mg/kg b.w., for which the effect was still noticeable the following day [Ettarh 2000].

For two weeks, three groups of 10 rats each received either 1 mL of distilled water (control group), 1 mL of a solution of caffeine corresponding to 20 mg/kg b.w. or 1 mL of a solution of cola extract at 320 mg/kg b.w.(extract not further specified; corresponding to 20 mg/kg b.w. of caffeine). Locomotor activity was significantly increased in both the caffeine and cola extract groups as compared to control ($p<0.05$). Onset of the effect in the cola extract group was slower and more gradual but more sustained than in the caffeine group [Scotto 1987].

Neurological effects
In a further study, three groups of 10 rats each received p.o. either 1 mL of distilled water, 20 mg/kg b.w. of caffeine in solution or cola extract containing an equivalent level of caffeine (320 mg/kg b.w.; extract not further specified) for 15 days. Cola treatment induced an increase in the cortical activity with a widening of the dominant frequency spectrum 7 to 10Hz band of EEG whereas caffeine alone induced a shift of the dominant frequency band towards higher frequencies [Vaille 1993].

Cardiovascular effects
Effects of cola on blood pressure were assessed in a 7 day experiment involving 4 groups of 10 rats each. Group 1 served as the control and consumed only normal rat feed (10.0 ± 0.5 g/day). Group 2 consumed normal feed (9.6 ± 1.0 g/day) mixed with ground cola (2:1). Group 3 consumed normal feed (10.5 ± 0.8 g/day) mixed with caffeine (1.0 g/120 g) at a level equivalent to the caffeine content of the cola in the feed of group 2. While group 4 consumed ground cola as the only feed (9.2 ± 1.2 g). Mean arterial pressure (MAP measured as mm Hg; control: 88.0 ± 1.2) was increased significantly in groups 2-4 (group 2: 110.8 ± 1.7, $p<0.001$; group 3: 108.4 ± 1.9, $p<0.001$; group 4: 108.6 ± 2.0, $p<0.001$) compared to the control; whereas there was no significant difference between groups 2-4. Furthermore, there were no significant differences in body weight change between all 4 groups [Osim 1993].

Gastrointestinal effects
Rats were treated with aqueous cola extracts (10 mg/100 g b.w.) either by gastric perfusion or by intravenous injection. Both administrations resulted in increased (60-70%) gastric acid secretion (measured by titration), the effect after gastric perfusion being slightly stronger [Ibu 1986].

Pharmacological studies in humans
Changes in parameters of optical performance were assessed in a study with 10 healthy volunteers who received a single oral dose of 30 g whole raw cola seed to be chewed. The parameters were pupil size, near point convergences, visual acuity, amplitude of accommodation and intraocular pressure. No changes were observed immediately after cola ingestion except for near point convergence and amplitude of accommodation which were improved. Exophoria was also changed to orthophoria in some subjects [Igwe 2007].

Pharmacokinetic properties
Differences in the pharmacokinetics of comparable doses of pure caffeine (20 mg/kg) with cola of comparable caffeine content (320 mg/kg extract) were observed in studies in matched samples of rats for single doses and exposure over 30 days (n=110 and 88 respectively). After single oral administration of caffeine solution and cola extract, analysis showed two peaks of caffeine concentration in both plasma and erythrocytes. However, in caffeine-treated animals these peaks occurred much later. The mean time to reach the first maximum concentration of caffeine after a single dose was 1 hour for cola and 1.5 hours for caffeine alone in both plasma and erythrocytes, to reach the second peak 3 and 8 hours (7 for erythrocytes) respectively. Caffeine when given alone was also eliminated in most measures at more than twice the rate as when given in cola. On chronic oral administration of caffeine and cola extract, the variations in plasma and erythrocyte caffeine concentrations show a peak of maximal concentration that also appears much earlier in animals treated by cola extract [Vaille 1993].

On EEG readings cola extracts demonstrated a more complex spectrum of effects consistent with the simultaneous presence of catechin, that partically antagonises the action of caffeine [Vaille 1993].

Preclinical safety data

Repeated dose and chronic toxicity studies
Male albino rats received p.o. either 1 mL of distilled water (control group) or 0.5 mL of an aqueous cola extract (100 g/200 mL) corresponding to 57 mg/kg b.w. every second day over 18 weeks (n = 24). After approximately 9 weeks of treatment, irritability, restlessness, local alopecia, diuresis and loss of appetite but no signs of weakness were observed. At the end of the study a decrease in body weight was found in the experimental rats. Increases in the weight of organs and of the levels of serum alkaline phosphatase, serum acid phosphatase and serum total cholesterol ($p<0.05$) were observed [Ikegwuonu 1981].

Reproductive toxicity
Three groups of 6 male albino rats received p.o. either 25 mg/kg b.w., 50 mg/kg b.w. or 100 mg/kg b.w. of an aqueous extract

once a day for 30 days. A fourth group received 1.0 mL of distilled water (control). On day 31 after the last dosing, blood samples were collected and the animals were then euthenised. Histological preparation of the testes was also carried out. There was a significant decrease in testosterone levels ($p<0.05$), sperm motility ($p<0.05$), sperm viability ($p<0.05$) and sperm count ($p<0.05$) in all groups relative to the control, but there was no significant change in sperm morphology. There was moderate to severe necrosis with the dissolution of numerous seminiferous tubules in testis [Oyedeji 2013].

Clinical safety data

The effects of cola ingestion during pregnancy were investigated in 100 women. The study showed that there was a correlation between cola consumption and head and chest circumference. Women who ingested cola gave birth to babies with smaller head and chest circumference than women who did not ingest cola. There was no correlation between cola consumption and birth weight [Abidoye 1990].

The concomitant consumption of cola with halofantrine hydrochloride (an antimalarial drug) was investigated in 15 healthy males in a randomised crossover design study. A single dose of 500 mg halofantrine was orally administered alone or with 12.5 g powdered cola nut. C_{max} for halofantrine decreased from 179 ± 119 to 98 ± 32 ng/mL ($p = 0.021$), and the AUC was reduced from 17,450 ± 4,611 to 11,821 ± 4,069 ng•h/mL ($p <0.001$) when co-administered with cola. C_{max} of the active metabolite, desbutylhalofantrine, decreased from 124 ± 41 to 62 ± 23 ng/mL ($p <0.001$) and the AUC from 13,341 ± 4,749 to 7,359 ± 3,018 ng•h/mL ($p <0.001$) when co-administered with cola.There was no significant difference for t_{max} and $t_{1/2}$ [Kolade 2008].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me, on behalf of my colleagues in ESCOP, to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate

URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ECHINACEAE ANGUSTIFOLIAE RADIX 2019

Narrow-leaved Coneflower Root

DEFINITION

Narrow-leaved coneflower root consists of the dried, whole or cut, underground parts of *Echinacea angustifolia* DC. It contains not less than 0.5 per cent of echinacoside ($C_{35}H_{46}O_{20}$; M_r 786.5), calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Narrow-leaved Coneflower Root].

CONSTITUENTS

The characteristic constituents are:

Caffeic acid derivatives (1.0-1.4%), principally echinacoside (0.3-1.3%), cynarin (1,3-dicaffeoylquinic acid; 0.1%) and chlorogenic acid [Bauer 2007; Perry 2001; Pellati 2005; Bradley 2006].

Alkamides (0.01-0.5%), principally isomeric dodeca-2*E*,4*E*,8*Z*,10*E/Z*-tetraenoic isobutylamides together with undeca-2*E/Z*-ene-8,10-diynoic acid isobutylamides, dodeca-2*E*-ene-8,10-diynoic acid isobutylamide and others [Bauer 1988, 1989a; Bauer 2007; Laasonen 2002; Bradley 2006].

Polysaccharides and glycoproteins [Wagner 1985; Beuscher 1995; Bradley 2006].

A small amount of essential oil (up to 0.1% V/m) is also present [Voaden 1972; Heinzer 1988; Mazza 1999].

CLINICAL PARTICULARS

Therapeutic indications

Internal use
Adjuvant therapy and prophylaxis of recurrent infections of the upper respiratory tract (common cold) [Melchart 1998; Bauer 2007; Bradley 2006].

Posology and method of administration

Dosage
Adult daily dose: 3 x 1 mL of extract (1:11, ethanol 30% V/V), 3 × 60 drops of tincture (1:5, ethanol 55% V/V) [Bauer 2007; Melchart 1998]; other equivalent preparations.

Method of administration
For oral administration.

Duration of administration
The duration of treatment should not exceed 8 weeks.

Contra-indications
Known hypersensitivity to plants of the Asteraceae (Compositae).

As with all immunostimulants, not recommended in cases of progressive systemic disorders such as tuberculosis, diseases of the white blood cell system, collagenoses, multiple sclerosis and other autoimmune diseases, AIDS or HIV infections [Bauer 2007, Ardjomand-Woelkart 2016].

Special warnings and special precautions for use
If the symptoms worsen or high fever occurs during the use of the medicinal product, medical advice should be sought.

There is a possible risk of allergic reactions in atopic patients. These patients should consult their doctor before using Echinacea.

Interaction with other medicaments and other forms of interaction
None reported in clinical studies.

E/S/C/O/P MONOGRAPHS

Only weak effects on the cytochrome P450 enzymes CYP1A2 and CYP3A4 were observed in *in vitro* assays [Modarai 2007; Woelkart 2007].

Pregnancy and lactation
Although there is no evidence of harmful effects during pregnancy [Gallo 2000; Perri 2006], in accordance with general medical practice the product should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Echinacea can trigger allergic reactions in atopic patients.

Allergic reactions due to Echinacea e.g. hypersensitive skin reactions are rather rare and mostly not serious [Ardjomand-Woelkart 2016].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Influence on immune functions
A 90% ethanolic extract (1:10) at a concentration of 1 µg/mL enhanced the phagocytosis index of human granulocytes by 17%; no effect was observed at concentrations of 1 ng/mL or lower. The chloroform-soluble fraction from the ethanolic extract increased phagocytosis by 34% at 0.1 µg/mL, while the water-soluble fraction stimulated phagocytosis by a maximum of only 17% at 1 µg/mL [Bauer 1988, 1989b].

Three fresh root extracts, a 50% ethanolic tincture, a cold water infusion and a hot water infusion, were tested using human blood in several assays of immune function: monocyte secretion of TNF-α, IL-10 and IL-12, and proliferation of peripheral blood mononuclear cells. All the extracts increased TNF-α production. The tincture caused a significant ($p=0.005$) increase and the cold water extract a non-significant increase in IL-12 production compared to controls on day 1 post-extraction. However, effects on peripheral blood mononuclear cell proliferation were minimal [Senchina 2005]. Other experiments with an extract (50% ethanol) showed an increase in peripheral blood mononuclear cells and tended to increase IL-10 production [McCann 2007].

A 55% ethanolic and an aqueous extract (80°C) inhibited IL-8 activity in both uninfected human epithelial cells and cells infected with rhinovirus (RV 14). A markedly enhanced IL-8 production was found for an aqueous extract (40 °C) in virus-stimulated cells [Vimalanathan 2009].

A root extract (standardized to contain > 4% of echinacoside, > 5% of high molecular weight polysaccharides of MW ca. 200 kDa and < 0.1% of isobutylamides), from which lipo-polysaccharides (LPS) had been removed to avoid non-specific responses of immunocompetent cells, produced significant and dose-dependent increases ($p<0.01$ at 1-10 µg/mL) in IFN-γ production in a murine T-lymphocyte cell culture stimulated by anti-CD3. A high molecular weight polysaccharide fraction from the extract produced a greater increase. Neither the extract nor the polysaccharide fraction had any effect on immune-stimulating activity in a murine macrophage cell line, indicated by a lack of effect on nitric oxide (NO) production. In contrast, the original LPS-containing extract was effective in activating the macrophages [Morazzoni 2005].

Significant ($p<0.05$) inhibition of prostaglandin E_2 production in LPS-stimulated RAW 264.7 mouse macrophages was shown for an ethanolic extract at a concentration of 15 µg/mL [LaLone 2007].

A dose-dependent inhibition of NO production and TNF-α release in RAW 264.7 macrophages was demonstrated (10-200 µg/mL) for a combination of extracts from narrow-leaved coneflower root obtained with various solvents. In macrophages incubated overnight with the extract at 100-200 µg/mL, and subsequently stimulated with *Salmonella enterica* subspecies *enterica* serovar Typhimurium, phagocytosis was significantly ($p<0.04$) enhanced and bacterial killing over 24 hours significantly ($p<0.026$) inhibited [Zhai 2007a].

An alkamide fraction and individual alkamides inhibited LPS-mediated activation of murine macrophages with IC_{50} values of 6 µg/mL for the fraction and 3-25 µg/mL for the individual compounds. Individual alkamides alone did not activate the macrophages. However, when the macrophages were pre-incubated with the total alkamide fraction and then stimulated with LPS, NO production was reduced when compared to cells treated only with LPS [Chen 2005].

Isolated alkamides (isomeric dodeca-2*E*,4*E*,8*Z*,10*E/Z*-tetraenoic acid isobutylamide, dodeca-2*E*,4*E*,8*Z*-trienoic acid isobutylamide and dodeca-2*E*,4*E*-dienoic acid isobutylamide) produced a dose-dependent induction of TNF-α mRNA in monocytes/macrophages. This effect was mediated by the cannabinoid receptor CB2 and also by multiple signal transduction pathways [Gertsch 2004]. The binding affinity of alkamides isolated from a carbon dioxide extract for rodent cannabinoid receptors CB1 and CB2 was evaluated in a standard receptor binding assay. Most of the alkamides showed affinities for CB2 receptors with Ki values lower than 20 µM [Woelkart 2005].

Further experiments showed that dodeca-2*E*,4*E*,8*Z*,10*Z*-tetraenoic acid isobutylamide and dodeca-2*E*,4*E*-dienoic acid isobutylamide bind to the CB2 receptor more strongly than endogenous cannabinoids. Both alkamides (50 nM) up-regulated constitutive IL-6 protein expression to 130-160% of the level seen in controls, while 500 nM of dodeca-2*E*,4*E*-dienoic acid isobutylamide inhibited expression. LPS-induced TNF-α, IL-1β and IL-12p70 were inhibited by 50 nM of the two alkamides in a CB2-independent manner [Raduner 2006].

Antioxidant activity
Methanolic and ethanolic (1:10, 85%) extracts exhibited antioxidant activity, including free radical scavenging and metal chelating [Sloley 2001; Hu 2000].

In the DPPH assay, an 80%-methanolic extract, cynarin and echinacoside, gave EC_{50} values of 231 µg/mL, 11.0 and 6.6 µM respectively [Pellati 2004].

Caffeic acid derivatives such as echinacoside inhibited free radical-induced degradation of collagen in a dose-dependent manner [Maffei Facino 1995].

Antimicrobial and antiviral activity
A high molecular weight fraction (M_r > 10,000 D) containing polysaccharides and glycoproteins exhibited antiviral activity against *Herpes simplex* virus type 1 in a plaque reduction assay [Beuscher 1995]. Antiviral activity was also shown for

echinacoside against vesicular stomatitis virus in L-929 mouse cells in a plaque reduction assay [Cheminat 1988].

An ethanolic (70%) extract, and an ethyl acetate fraction thereof, showed activity against rhinovirus, *Herpes simplex* virus and influenza virus [Hudson 2005].

The n-hexane fraction from a 95%-ethanolic extract of fresh root exhibited marginal near-UV light (300-400 nm)-activated phototoxicity and hence antifungal activity against the fungal pathogens *Candida shehata*, *Cryptococcus neoformans* and *Fusarium oxysporum*, but not against *Candida albicans* [Merali 2003].

Other effects
Alkamides have been shown to exert anti-inflammatory activity by inhibiting the enzymes 5-lipoxygenase (5-LOX) and cyclo-oxygenase; their IC_{50} values depended on the particular structure and ranged from 8 to 83% and 23 to 75% respectively [Wagner 1989; Müller-Jakic 1994]. A 70%-ethanolic extract inhib-ited 5-LOX activity with an IC_{50} of 0.44 µg root/mL [Merali 2003].

Treatment of H4 human neuroglioma cells with a carbon dioxide extract for 48 hours led to significant suppression of PGE_2 formation ($p<0.001$). Experiments with eight different alkamides isolated from the extract demonstrated a direct inhibitory effect by three alkamides: undeca-2*Z*-ene-8,10-diynoic acid isobutylamide, dodeca-2*E*-ene-8,10-diynoic acid isobutylamide and dodeca-2*E*,4*Z*-diene-8,10-diynoic acid 2-methylbutylamide. All three alkamides were shown to suppress COX-2 activity but none inhibited COX-2 mRNA and protein expression. The results suggested that certain alkamides may inhibit COX-2-dependent PGE_2 formation at sites of inflammation [Hinz 2007].

Ethanolic extracts from narrow-leaved coneflower root and a 1:1 blend of purple coneflower root and narrow-leaved coneflower root inhibited human cytochrome P450 3A4 (CYP 3A4) activity with relative IC_{50} values of 1.05% and 6.73% respectively (expressed as percentage of full strength of stock solutions after serial dilutions), compared to 0.04% for St. John's wort [Budzinski 2000]. Other experiments demonstrated CYP enzyme-mediated degradation of alkamides in human liver microsomes. Metabolism was dependent on both the structure of individual compounds and the combination present in the assay [Matthias 2005].

A hexane extract (3 to 30 µg/mL) was reported as inhibiting Pgp activity in the human proximal tubular cell line HK-2 [Romiti 2008].

A hexane extract exhibited concentration-dependent (3-300 µg/mL) cytotoxic activity in human pancreatic (MIA PaCa-2) and colon cancer (COLO320) cells with IC_{50} values of 82.86 and 31.78 µg/mL respectively [Chicca 2007].

In vivo experiments

Phagocytosis-stimulating effects
In the carbon clearance test in mice, oral administration of a 90% ethanolic extract (1:10) daily for 2 days at 0.5 mL/kg b.w. caused a 1.7-fold increase in phagocytosis [Bauer 1988, 1989b].

Immunomodulating effects
An extract (standardized to contain > 4% of echinacoside, > 5% of high molecular weight polysaccharides of MW ca. 200 kDa and < 0.1% of isobutylamides), administered orally to mice at 1 g/kg/day one day before and for six days after infection with Candida albicans, reduced mortality by 30% ($p<0.01$). In *C. albicans*-infected mice treated orally with cyclosporin A (10 mg/kg/day for 5 days) to cause immunosuppression, as well as with the extract orally at 1 g/kg/day for 7 days, mortality was reduced by 40% ($p<0.01$) [Morazzoni 2005].

To demonstrate that Echinacea treatment restored mild stress-induced immune changes to normal levels, BALB/c mice were given an extract obtained with various solvents (130 mg/kg b.w. p.o.) once a day for 7 consecutive days. On the 4th day of treatment they were immunized with sheep red blood cells to induce an immune response; and immune cells were collected 12–15 hours after the last dose of extract. Compared to the vehicle only (5% ethanol) and no treatment control groups, treatment with the extract demonstrated a significant increase in the percentage of peripheral blood lymphocytes ($p=0.001$) and the splenic lymphocyte subpopulation percentage ($p=0.004$); and more specifically in the CD49 cell subset ($p<0.05$). *Ex vivo* experiments with stimulated splenocytes showed a significant increase in the production of IFN-γ ($p<0.05$), IL-4 ($p=0.046$), IL-2 ($p=0.037$) and IL-10 ($p=0.057$). There was significantly reduced production of TNF-α ($p=0.004$) and IL-1β ($p=0.007$) [Zhai 2007b].

Rats which were injected with the antigen keyhole limpet haemocyanin and re-exposed to the same antigen on days 14 and 35, were then treated orally with an extract (3.3 g/L, not further specified) in their drinking water over a period of 6 weeks. The animals showed a significant augmentation of their primary and secondary IgG responses to the antigen compared to control on days 7 ($p=0.04$), 21 ($p=0.005$) and 27 ($p=0.002$) of treatment. After 31 days, there was no longer a significant difference between the Echinacea-treated and control groups [Rehman 1999].

Pharmacological studies in humans
In a randomized, double-blind, placebo-controlled study, the effects of several extracts on experimentally-induced rhinovirus type 39 infections (a well-established model for study of the pathogenesis and treatment of common cold) were evaluated in 399 healthy young adult volunteers found by screening to be susceptible to this virus. Three different extracts, prepared from the same batch of *E. angustifolia* root but having distinct phytochemical profiles, were used: a supercritical carbon dioxide extract (73.8% alkamides, no polysaccharides), a 60%-ethanolic extract (2.3% alkamides, 48.9% polysaccharides) and a 20%-ethanolic extract (0.1% alkamides, 42.1% polysaccharides). The volunteers received 3 × 1.5 mL of the extract preparations (equivalent to 3 × 300 mg of root) or placebo daily, either as prophylactic pre-treatment (for 7 days before virus challenge) or treatment (from virus challenge to day 5), or in both phases. No significant effects of the extracts were observed on rates of infection or severity of symptoms [Turner 2005].

Combination preparation
The effects of a combination of Echinacea root dry ethanolic extracts on expression of leucocyte heat shock protein 70 (hsp70), erythrocyte haemolysis, plasma antioxidant status, standard serum chemistry, haematological values and plasma alkamide concentrations were studied in 11 healthy individuals aged 26-61 years. The volunteers were evaluated at baseline (day 1) and on day 15 after taking 2 tablets (each containing extracts equivalent to 675 mg of purple coneflower root + 600 mg of narrow-leaved coneflower root) daily for 14 days. Significant increases were found in leucocyte hsp70 expression after mild heat shock ($p = 0.029$) and in white cell counts ($p = 0.043$). A preventative effect against free radical-induced erythrocyte haemolysis ($p = 0.006$), indicative of an antioxidant effect, was also observed [Agnew 2005].

Clinical studies
A double-blind, placebo-controlled study evaluated the efficacy of root extracts from two *Echinacea* species in the prevention of upper respiratory tract infections in 289 volunteers. In randomized groups the volunteers were instructed to take 2 × 50 drops (about 2 × 1 mL) of an ethanolic extract (1:11 in 30% ethanol) of narrow-leaved coneflower root (group A, n = 100) or purple coneflower root (group B, n = 99), or placebo (group C, n = 90), daily on 5 days per week (Monday to Friday) for 12 weeks. Of the 244 participants fully complying with the protocol, 84, 85 and 75 were in groups A, B and C respectively. The average time to the occurrence of first upper respiratory tract infections was 66, 69 and 65 days in groups A, B and C respectively, and 32%, 29% and 37% of participants had at least one upper respiratory tract infection. Although suggesting a relative reduction of 20% in risk of infection in the purple coneflower root group and 13% in the narrow-leaved coneflower root group, the results were not significant; a prophylactic effect of the extracts was not evident [Melchart 1998].

Pharmacokinetic properties
In a randomized crossover study 11 healthy subjects received a single oral dose of 2.5 mL of a 60%-ethanolic extract in the morning following an overnight fast. C_{max} for dodeca-2*E*,4*E*,8*Z*,10*E/Z*-tetraenoic acid isobutylamides was approximately 8 ng/mL (slow absorber) or 11 ng/mL (fast absorber) [Woelkart 2005].

Combination preparation
Alkamides were rapidly absorbed and measurable in plasma from 9 healthy volunteers 20 minutes after ingestion of 4 tablets, each containing dry ethanolic extracts corresponding to 675 mg of purple coneflower root + 600 mg of narrow-leaved coneflower root, and remained detectable for up to 12 hours. The maximum plasma concentration of total alkamides (average 336 ± 131 ng eq/mL) was reached within 2.3 hours. Caffeic acid conjugates could not be identified in any plasma sample [Matthias 2005].

Preclinical safety data
In the Ames mutagenicity test conflicting results were obtained with three fluid extracts of narrow-leaved coneflower root. One fluid extract showed mutagenic potential in *Salmonella typhimurium* strains TA98 and TA100 (with or without S9 activation), while a second fluid extract gave positive results only in TA98 and a third one gave negative results in both strains [Schimmer 1994].

Clinical safety data
Several meta-analyses on clinical use and safety generally concluded that the use of Echinacea is safe, notwithstanding that several adverse reactions have been reported. However, accurate information to evaluate these reports, e.g. data on the Echinacea species used, plant parts, type of extract, dosage and co-administration of other medicines, is missing [Soon 2001; Mullins 2002; Huntley 2005; Gryzlak 2007; Freeman 2008; Kocaman 2008; Karsch-Völk 2014; Ardjomand-Woelkart 2016].

Mild adverse effects were reported by 18 out of 100 subjects who took 2 × 1 mL of a hydroethanolic extract of narrow-leaved coneflower root daily for 12 weeks in a randomized study, compared to 11 out of 90 subjects in the placebo group [Melchart 1998].

In a randomized study of experimental rhinovirus infections, 19 out of 437 volunteers (4%) reported adverse events during a prophylaxis phase; in 4 volunteers out of 164 (2%) in the verum group and 5 out of 274 (2%) in the placebo group the adverse effects were judged to be possibly related to the medication. During the treatment phase, 15 out of 315 (5%) in the verum group reported an adverse event possibly related to the treatment compared to 4 out of 104 (4%) in the placebo group. Gastrointestinal side effects were the most frequent [Turner 2005].

In a prospective controlled study involving 412 women, the pregnancy outcome was investigated following gestational exposure to (undefined) solid or liquid preparations of *Echinacea* (*angustifolia*, *purpurea* and in one case *pallida*). In the group of 206 women who used Echinacea products during pregnancy (112 in the first trimester), 13 spontaneous abortions and 6 major malformations (4 occurring after exposure to Echinacea in the first trimester) were reported, compared to 7 spontaneous abortions and 7 major malformations in the matching control group of 206 women. There was no significant difference found between the Echinacea and control groups in terms of pregnancy outcome, delivery method, maternal weight gain, gestational age, birth weight or fetal distress [Gallo 2000].

A systematic review of evidence from the use of Echinacea during pregnancy and lactation led to the conclusion that Echinacea (including *Echinacea angustifolia*) is not teratogenic [Perri 2006].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use

SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ECHINACEAE PALLIDAE RADIX 2018

Pale Coneflower Root

DEFINITION

Pale coneflower root consists of the dried, whole or cut, underground parts of *Echinacea pallida* Nutt. It contains not less than 0.2 per cent of echinacoside ($C_{35}H_{46}O_{20}$; M_r 786.5), calculated with reference to the dried drug.

The material complies with the European Pharmacopoeia [Pale Coneflower Root].

CONSTITUENTS

The characteristic constituents are:

- Caffeic acid derivatives, especially echinacoside (0.5-1.6%) [Bauer 1987a, 1987b, 1988a, 1989, 1990, 1994 2007; Brown 2010; Cheminat 1988; Pellati 2004, 2005; Thomson 2012].
- Essential oil (0.2-2.0%) [Bauer 1988a, 1990, 1994, 2007; Heinzer 1988] containing polyacetylenes and polyenes including alkenes such as pentadeca-1,8*Z*-diene [Bauer 2007; Heinzer 1988], and a range of unsaturated alkyl ketones (ketoalkenes, ketoalkenynes and ketoalkenonen) principally pentadeca-8*Z*-ene-2-one together with pentadeca-8*Z*,11*Z*-diene-2-one, pentadeca-8*Z*,13*Z*-diene-11-yne-2-one (Bauer keton 24), tetradeca-8*Z*-ene-11,13-diyne-2-one and others [Bauer 1987a, 1988a, 1989, 1990, 1994, 2007; Heinzer 1988; Pellati 2006; Morandi 2008; Thomsen 2012].
- 8-Hydroxyketoalkenynes, produced by oxidation of unsaturated alkyl ketones on storage of the dried drug. They include 8-hydroxytetradec-9*E*-ene-11,13-diyn-2-one, 8-hydroxypentadec-9*E*-ene-11,13-diyn-2-one and 8-hydroxypentadec-9*E*,13*Z*-dien-11-yn-2-one [Bauer 1987a, 1988a, 1989, 1990, 1994, 2007; Bradley 2006].
- A small amount of alkamides (0.001%): isomeric dodeca-2*E*,4*E*,8*Z*,10*E*/*Z*-tetraneoic acid isobutylamides (Bauer alkamides 8) and various others [Bradley 2006; Chen 2005; LaLone 1009].
- Arabinans, arabinogalactan proteins and other polysaccharides [Beuscher 1995; Classen 2005; Thude 2005].

CLINICAL PARTICULARS

Therapeutic indications
Adjuvant therapy and prophylaxis of recurrent infections of the upper respiratory tract (common cold) [Bräunig 1993; Bradley 2006; Bauer 2009].

Posology and method of administration

Dosage

Adult daily dose: Hydroethanolic extracts corresponding to 900 mg of crude drug [Bradley 2006; Bräunig 1993; Bauer 2009]; other equivalent preparations.

Method of administration
For oral administration.

Duration of administration
The duration of treatment should not exceed 8 weeks.

Contra-indications
Known hypersensitivity to plants of the Asteraceae (Compositae).

As with all immunostimulants, not recommended in cases of progressive systemic disorders such as tuberculosis, diseases of the white blood cell system, collagenoses, multiple sclerosis and other autoimmune diseases, AIDS or HIV infections [Bauer 2007; Ardjomand-Woelkart 2016].

Special warnings and special precautions for use
If the symptoms worsen or high fever occurs during the use of the medicinal product, medical advice should be sought.

There is a possible risk of allergic reactions in atopic patients. These patients should consult their doctor before using Echinacea.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
Although there is no evidence of harmful effects during pregnancy [Gallo 2000; Perri 2006], in accordance with general medical practice the product should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Echinacea can trigger allergic reactions in atopic patients.

Allergic reactions due to Echinacea e.g. hypersensitive skin reactions are rather rare and mostly not serious [Ardjomand-Woelkart 2016].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Influence on immune function
A 90% ethanolic extract (1:10) at a concentration of 10 µg/mL enhanced the phagocytosis index of human granulocytes by 23%; no effect was observed at concentrations of 1 ng/mL or lower. The chloroform-soluble fraction from the ethanolic extract increased phagocytosis by 39% at 0.1 µg/mL, while the water-soluble fraction stimulated phagocytosis by a maximum of only 14% at 1 µg/mL [Bauer 1988b].

A 55% ethanolic and an aqueous extract weakly inhibited IL-8 activity in both uninfected and Rhinovirus (RV 14) infected human epithelial cells. By contrast a markedly enhanced IL-8 production was found for the hexane fractions of the hydro-ethanolic extract [Vimalanathan 2009].

A high molecular weight fraction (M_r > 10,000 Da) containing polysaccharides and glycoproteins enhanced the proliferation of mouse spleen cells and stimulated the production of interferon (IFNα/β) and immunoglobulin M as well as the number of antibody-producing cells in spleen cell cultures. It also increased the production of cytokines (such as IL-1, IL-6 and TNF-α) and nitric oxide in mouse macrophage cultures [Beuscher 1995; Bodinet 1999]. Incubation of this fraction with human monocytes enhanced the production of IL-1, IL-6 and TNF-α [Bodinet 1999].

An arabinogalactan-protein fraction from an aqueous extract showed a stimulated proliferation of C3H/HeJ mouse spleen cells at concentrations up to 100 µg/mL, a dose-dependent increase in IgM titres of NMRI mouse spleen cell cultures, a dose-dependent increase in IL-6 production and a dose-dependent increase in nitrite production in alveolar mouse macrophages [Classen 2006].

Three extracts of fresh pale coneflower root (a 50%-ethanolic tincture, a cold water infusion and a hot water infusion) were tested in several assays of immune functions in human blood: monocyte secretion of TNF-α, IL-10 and IL-12 and proliferation of peripheral blood mononuclear cells. The cold water extract enhanced TNF-α production on day 1, but a reduction was seen at day 4 for all the extracts. The cold water extract caused a significantly greater production of IL-12 than the control on day 1 ($p<0.05$). However, effects on T-cell proliferation were minimal [Senchina 2005].

A dose-dependent inhibition of NO production and TNF-α release in RAW 264.7 macrophages was demonstrated for a combination of extracts obtained with various solvents (10-200 µg/ml). Stimulation of the macrophages with *Salmonella* after an overnight incubation with the extract had no effect on phagocytosis but showed increased bactericidal activity ($p=0.002$ at 200 µg/ml) [Zhai 2007a].

Additional experiments with the same combination of extracts showed no direct inhibition of NO release. An immune blotting assay demonstrated that the extract (100 µg/mL) inhibited iNOS protein expression in LPS-treated macrophages. A dose-dependent enhancing effect on arginase activity by the extract (10-200 µg/mL) was seen in RAW 264.7 cells incubated with 8-bromo-cAMP. None of the doses (19-200 µg/mL) had an effect on cell viability [Zhai 2009a].

Significant inhibition ($p<0.05$) of prostaglandin E_2 production in LPS-stimulated RAW 264.7 mouse macrophages was shown for an ethanolic extract at a concentration of 15 µg/mL [LaLone 2007]. This inhibition was also reported for a 96% ethanolic extract (25 µg/mL); fractionation of this extract revealed Bauer ketones which inhibited PGE_2 production at a concentration of 1 µg/mL [LaLone 2009].

An alkamide fraction and individual alkamides inhibited LPS-mediated activation of murine macrophages with IC_{50} values of 6 µg/ml for the fraction and 3-25 µg/ml for individual compounds. Alkamides alone failed to activate the macrophages, while pre-incubation of macrophages with the alkamide fraction before LPS stimulation reduced NO production [Chen 2005].

Antioxidant activity
Methanolic and ethanolic (85%, 1:10) extracts exhibited anti-oxidant activity, including free radical scavenging and transition metal chelating [Hu 2000; Sloley 2001].

Caffeic acid derivatives such as echinacoside inhibited free radical-induced degradation of collagen in a dose-dependent manner [Maffei Facino 1995].

In the DPPH assay, an 80% methanolic extract and isolated echinacoside gave EC_{50} values of 167 µg/mL and 6.6 µM respectively [Pellati 2004].

Antimicrobial and antiviral activity
Extracts of pale coneflower root exhibited near UV-mediated phototoxic and antifungal activity, measured by inhibition of the growth of *Candida shehata, Cryptococcus neoformans, Candida albicans* (B-resistant strains) and *Trichophyton mentagrophytes*. The activity was attributed primarily to ketoalkenes and keto-alkynes [Binns 2000; Merali 2003].

An aqueous and two ethanolic (55% and 70%) extracts showed no activity against rhinovirus, *Herpes simplex virus* and influenza virus [Hudson 2005].

A high molecular weight fraction (M_r > 10,000 Da) containing polysaccharides and glycoproteins exhibited antiviral activity against *Herpes simplex* virus type 1 in a plaque-reduction assay [Beuscher 1995].

Antiviral activity of echinacoside against vesicular stomatitis virus in L-929 mouse cells was demonstrated in a plaque reduction assay [Cheminat 1988].

Other effects
A 95% ethanolic extract (1:10) inhibited 5-LOX activity with an IC_{50} of 1.08 µg/mL [Merali 2003].

A hexane extract (0.3 to 300 µg/mL) inhibited P-glycoprotein (Pgp) activity in the human proximal tubular cell line HK-2. The maximal inhibition was found with 3 µg/mL. At higher concentrations a reduction of cell viability was seen. Bioassay-guided fractionation revealed several polyacetylenes and polyenes with Pgp inhibiting activity [Romiti 2008]. An ethanolic extract (5 mg/mL, 96%) showed a significant ($p<0.01$) inhibition of Pgp activity [Qiang 2013].

A concentration-dependent (3-300 µg/mL) cytotoxic activity of a hexane extract in human pancreatic (MIA PaCa-2) and colon cancer (COLO320) cells was reported (IC_{50} 46.4 and 10.6 µg/mL respectively, $p<0.05$) [Chicca 2007]. Bioassay-guided fractionation led to the isolation of two polyacetylenes and three polyenes with IC_{50} values ranging from 9.3 to 35.6 µg/mL [Pelatti 2006].

The cytotoxic activity of two polyacetylenes and three polyenes was evaluated in MIA PaCa-2 and COLO320 cell lines. The five compounds caused a significant ($p<0.05$) dose-dependent decrease in MIA PaCa-2 and COLO320 cell viability after 72 h exposure (IC_{50} for the most active one, 32.17 and 2.34 µM in MIA PaCa-2 and COLO320 respectively). Pentadeca-(8*Z*,13*Z*)-dien-11-yn-2-one showed a significant ($p<0.05$) increase of caspase 3/7 activity (1.51 and 1.47 fold higher than the vehicle in MIA PaCa-2 and COLO320 cells respectively) as well as significantly enhanced intranucleosomal DNA fragments (2.97 and 2.32-fold higher than the vehicle in MIA PaCa-2 ($p<0.01$) and COLO320 cells ($p<0.05$), respectively) [Chicca 2008]. The compound also showed a concentration-dependent cytotoxicity on human leukaemia (Jurkat and HL-60), breast carcinoma (MCF-7) and melanoma (MeWo) cells. The ability to arrest the cell cycle in the G1 phase was demonstrated in HL-60 cells [Chicca 2010].

A concentration-dependent (5-75 µg/mL) inhibition of cell proliferation was found for a methanolic extract (not further specified) and isolated pentadeca-(8*E*,13*Z*)-dien-11-yn-2-one in Hela and C6 cell lines [Yaghoglu 2013].

A 55% ethanolic extract (not further specified) inhibited CYP3A4 activity with an IC_{50} of 66.08 µg/ml. An aqueous fraction thereof showed a lower activity (IC_{50} 169.6 µg/mL), whereas an ethanolic fraction alone had no activity [Modarai 2010].

In vivo experiments

Phagocytosis-stimulating effects
In the carbon clearance test in mice, oral administration of a 90% ethanolic extract (1:10) daily for 2 days at 0.5 ml/kg b.w. increased phagocytosis 2.2 fold. When chloroform and water fractions of this extract were administered separately at concentrations corresponding to their content in the original extract, the lipophilic fraction (2.6-fold increase) proved more active than the hydrophilic (1.3-fold increase) [Bauer 1988b].

Intravenous injection of 50, 100 or 500 µl of a high molecular weight fraction (M_r > 10,000 Da) containing polysaccharides and glycoproteins significantly increased the concentration of the cytokine IL-1 in the serum of mice ($p<0.05$) [Beuscher 1995]. A single oral administration of this fraction to mice at 3.7 mg per animal significantly enhanced antibody production in Peyer's patch cells [Bodinet 1999].

Immunomodulating effects
Male BALB/c mice received a preparation combining extracts using various solvents (130 mg/kg b.w. p.o., once a day for 7 consecutive days) and were immunized with sheep red blood cells. Four days later immune cells were collected. Compared to the vehicle only (5% ethanol) control and a no-gavage control, the preparation significantly ($p<0.001$) increased the percentage of lymphocytes in peripheral blood and significantly ($p=0.004$) increased splenic lymphocytes, but did not demonstrate a significant effect on splenic NK cell and B-cell subpopulations. Compared to the vehicle control, the preparation demonstrated a significant ($p<0.035$) increase in NK cell cytotoxicity and interferon-γ production, significantly ($p=0.05$) increased production of IL-4 and IL-10, and significantly reduced the production of TNF-α ($p=0.004$) and IL-1β ($p=0.007$) [Zhai 2007b].

In a further experiment, mice received the same extract preparation and treatment protocol, and 3 days before harvesting peritoneal exudate cells at the end of treatment, an inflammatory cell response was induced with 3% protease peptone i.p. There were no significant differences in IL-1β, IL-10 and NO production compared to the vehicle control group, in cells incubated with or without LPS [Zhai 2007a].

Wound healing effects
Topical application of an extract (100 mg dry ethanol extract (1:10 w/v)/mL gel) or echinacoside (0.4 mg/mL gel) to an abraded wound on rats showed a reduction of inflammation and erythema after 24 and 48 hours. After 72 hours no further signs of inflammation were observed in the two treated groups while the controls (vehicle treatment only) still showed clear signs. Compared to control a markedly enhanced wound-healing effect was seen after 48 and 72 hours in the extract and echinacoside treated groups. Histological examination showed that the injured area was covered by a crusty exudate and a generalised acute serous inflammation in the dermis of animals treated with the extract. After 48 hours new tracts of epidermis were detectable while the scab was also present. After 72 hours fully recovered epidermis was seen in the treated groups [Speroni 2002].

A preparation consisting of a combination of extracts obtained using various solvents (130 mg/kg b.w.) was administrated orally to hairless mice for 3 days prior to and 4 days after wounding with a dermal biopsy on the back. Mice were either exposed to 3 cycles of 12 h restraint stress prior to and 4 cycles after wounding (just before each dose of the preparation) or kept food and water deprived for the same 12 h but not restrained, or given food *ad lib* and kept unrestrained. Wound healing was accelerated by the preparation in the stressed mice but no effect was seen in the non-stressed mice compared to their controls [Zhai 2009b].

Clinical studies
In a randomized, double-blind study, 160 patients (83 males and 77 females) with influenza-like infections of the upper respiratory tract were treated for 8-10 days with either a hydroalcoholic liquid extract (not further specified) at a daily dose corresponding to 900 mg of dried root (n = 80) or placebo (n = 80). Significant improvements in four major symptoms, common cold, weakness, pain in arms and legs, and headache ($p<0.0001$), and in the overall symptom score ($p<0.0004$),

were observed in the verum group compared to the placebo group. Also, the duration of illness was significantly shorter in verum patients ($p<0.0001$): in those with putative bacterial infections, 9.8 days compared to 13.0 with placebo; in those with putative viral infections, 9.1 days compared to 12.9 with placebo [Bräunig 1993].

Pharmacokinetic properties
A single oral administration of dodeca-2*E*,4*E*,8*E*,10*E*/*Z*-tetraenoic acid isobutylamides (tetraenes) to male Sprague-Dawley rats (2.5 mg/kg) resulted in rapid absorption (T_{max} 15 minutes) and distribution in the liver and brain tissues within 8 minutes. The maximum amount of the tetraenes, calculated as $AUC_{0-\infty}$, in different brain parts, plasma and liver were 1764 to 6192, 794 and 1254 min x ng/mL respectively. $T_{0.5}$ was 1 and 4 hours in plasma and brain regions respectively [Woelkart 2009].

Preclinical safety data
No data available.

Clinical safety data
Several meta-analyses on clinical use and safety generally concluded that the use of Echinacea is safe. There are occasional reports of adverse reactions: however, accurate information to evaluate these reports e.g. data on the Echinacea species used, plant parts, type of extract, dosage and co-administration of other medicines, are missing [Soon 2001; Mullins 2002; Huntley 2005; Gryzlak 2007; Freeman 2008; Kocaman 2008; Karsch-Volk 2014; Ardjomand-Woelkart 2016].

In a prospective controlled study involving 412 women, the pregnancy outcome was investigated following gestational exposure to (undefined) solid or liquid preparations of *Echinacea* (*angustifolia*, *purpurea* and in one case *pallida*). Of 206 women who used Echinacea products during pregnancy, 112 used them in the first trimester. In the Echinacea group, 13 spontaneous abortions as well as 6 major malformations (4 of these occurring after exposure to Echinacea in the first trimester) were reported, compared to 7 spontaneous abortions and 7 major malformations in the control group. No statistically significant difference was seen between the groups in terms of pregnancy outcome, delivery method, maternal weight gain, gestational age, birth weight or fetal distress [Gallo 2000].

A systematic review of the evidence from the use of Echinacea during pregnancy and lactation concluded that Echinacea (including *Echinacea pallida*) is not teratogenic when used during pregnancy [Perri 2006].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ECHINACEAE PURPUREAE HERBA 2021

Purple Coneflower Herb

DEFINITION

Purple coneflower herb consists of the dried, whole or cut flowering aerial parts of *Echinacea purpurea* (L.) Moench. It contains not less than 0.1 per cent for the sum of caftaric acid ($C_{13}H_{12}O_9$; Mr 312.2) and cichoric acid ($C_{22}H_{18}O_{12}$; Mr 474.3) (dried drug).

The material complies with the monograph of the European Pharmacopoeia [Purple Coneflower Herb].

CONSTITUENTS

The characteristic constituents are:

Caffeic acid derivatives, predominantly cichoric acid (2,3-*O*-dicaffeoyl-tartaric acid) (0.5-5.7%) [Bauer 1988, 1998; Brown 2010; Pellati 2005; Iranshahi 2008; Upton 2007; Thomson 2012], 2-*O*-feruloyl-tartaric acid and 2-*O*-caffeoyl-3-*O*-coumaroyl-tartaric acid [Soicke 1988].

A series of alkamides (alkylamides) with isomeric dodeca-2*E*,4*E*,8*Z*,10*E*/*Z*-tetraenoic acid isobutylamides (0.02-0.53%) as the main compounds [Bauer 1988; Bohlmann 1983; Upton 2007; Thomson 2012].

Polysaccharides (PS) such as PS I (a 4-*O*-methyl-glucuronoarabinoxylan with an average MW of 35,000 D), PS II (an acidic arabinorhamnogalactan of MW 450,000 D) and a xyloglucan (MW 79,500 D) have been isolated from the herb. A highly-branched acidic arabinogalactan-protein (average MW of 1.2 × 106 D, with a protein content of less than 10%), inulin-type fructans (average MW 6,000 D) and a pectin-like polysaccharide have been isolated from the pressed juice from fresh herb [Heise 2015; Classen 2000, 2009; Bauer 1998; Proksch 1987; Stuppner 1985; Wagner 1981,1985].

A small amount of essential oil (up to 0.1% V/m) is also present [Mazza 1999; Pellati 2005].

Other constituents include flavonoids (0.48%) such as quercetin, kaempferol and isorhamnetin and their glycosides, found in the leaves [Malonga-Makosi 1983]; essential oil (0.08-0.32%) [Bomme 1992; Kuhn 1939; Neugebauer 1949] containing borneol, bornyl acetate, pentadeca-8-ene-2-one, germacrene D, caryophyllene, caryophyllene epoxide [Bos 1988] and a germacrene alcohol, germacra-4(15),5*E*,10(14)-triene-1β-ol [Bauer 1988] and as minor constituents, 13-hydroxy-octadeca-9*Z*,11*E*,15*Z*-trienoic acid, methyl-*p*-hydroxycinnamate, a labdane derivative and polyacetylenes [Becker 1985; Schulte 1967].

CLINICAL PARTICULARS

Therapeutic indications

Internal use
Adjuvant therapy and prophylaxis of recurrent infections of the upper respiratory tract (common colds) and also of the urogenital tract [Bauer 2007; Brinkeborn 1996; Coeugniet 1986; Goel 2004, 2005; Hoheisel 1997; Schulten 2001; Schöneberger 1992].

External use
As an adjuvant for the treatment of superficial wounds [Bauer 2007; Viehmann 1978].

Posology and method of administration

Dosage

Internal use
Adult daily dose: 6-9 mL of pressed juice; other equivalent preparations at

E/S/C/O/P MONOGRAPHS

comparable dosage [Bauer 2007; Brinkeborn 1996; Coeugniet 1986; Hoheisel 1997; Schulten 2001; Schöneberger 1992].

Children: Proportion of adult dose according to age or body weight.

External use
Semi-solid preparations with a minimum of 15% of pressed juice [Bauer 2007; Viehmann 1978].

Method of administration
For oral administration and topical application.

Duration of administration
The duration of continuous treatment should not exceed 8 weeks [Bauer 2007].

Contra-indications
Known hypersensitivity to plants of the Asteraceae (Compositae).

As with all immunostimulants, not recommended in cases of progressive systemic disorders such as tuberculosis, diseases of the white blood cell system, collagenoses, multiple sclerosis and other autoimmune diseases, AIDS or HIV infections [Bauer 2007; Ardjomand-Woelkart 2016].

External use
Hypersensitivity to plants of the Compositae.

Special warnings and special precautions for use
If the symptoms worsen or high fever occurs during the use of the medicinal product, medical advice should be sought.

There is a possible risk of allergic reactions in atopic patients. These patients should consult their doctor before using Echinacea.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
Although there is no evidence of harmful effects during pregnancy [Gallo 2000; Perri 2006], in accordance with general medical practice the product should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Echinacea can trigger allergic reactions in atopic patients.

Allergic reactions due to Echinacea e.g. hypersensitive skin reactions are rather rare and mostly not serious [Ardjomand-Woelkart 2016].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Influence on immune functions
A lyophilisate of the pressed juice at concentrations from 1.0 to 5.0 mg/mL significantly and dose-dependently increased the ratio of phagocytosing human granulocytes from 79% to 95% ($p<0.001$), and at 5.0 mg/mL increased the phagocytosis index of starch grains (mean number of phagocytosed grains per granulocyte) by more than 50% ($p<0.01$). At the highest tested dose, 12.5 mg/mL, the number of phagocytosing granulocytes and the phagocytosis index decreased, probably due to cytotoxic effects [Stotzem 1992].

Stimulation of phagocytosis has been verified in further assays [Bittner 1969; Fanselow 1984; Tympner 1981]. Similar results were reported with the alkamide fraction, polysaccharides and cichoric acid [Bauer 1989; Soicke 1988; Stimpel 1984].

Cultures of cytologically unchanged human bone marrow cells had a significantly enhanced mitotic index of granulo- and monopoesis after incubation for up to 72 hours with 0.2 or 2.0 mg/mL lyophilized pressed juice ($p=0.99$). In blood cultures of patients suffering from chronic myeloic leukaemia or osteomyelosclerosis, the number of mature granulocytes was mostly unchanged. In blood cultures of patients suffering from acute non-lymphatic leukaemia the total count of functionally mature granulocytes increased. More importantly, there was a highly significant reduction of granuloblasts due to a changed pattern of differentiation [Krause 1984].

Stimulation of T-lymphocyte populations has been observed in the T-lymphocyte transformation test. Lyophilized pressed juice stimulated incorporation of ^{3}H-thymidine at medium concentrations (50-500 µg/mL), while high concentrations (≥ 2500 µg/mL) showed a suppressive or cytotoxic effect [Hoh 1990].

In macrophage cultures from mice, lyophilized pressed juice immediately induced a sharp increase in chemiluminescence [Hoh 1990]. Similar findings were seen in granulocyte cultures from healthy human donors; a 24% increase in the formation of oxygen radicals has been demonstrated after 60 minutes of pre-incubation with lyophilized pressed juice at 50 µg/mL and suboptimal stimulation with zymosan, suggesting a significant increase in previously depressed granulocyte activity in accordance with the results of the chemiluminescence method [Krause 1986].

After elicitation of submaximal IL-2 production in human Jurkat T cells, treatment with a 95%-ethanolic extract resulted in dose-dependent suppression of IL-2 production, significant at 50 and 100 µg/mL ($p<0.0001$). The effect was due to alkamides, whereas the caffeic acid derivatives were not active [Sasagawa 2006].

Incubation of mice bone marrow-derived dendritic cells with a 70% ethanolic extract (50 and 150 µg/mL) for 48 h inhibited the expression of MHC class II, CD86, and CD54 receptors, and the activity of COX-2 [Benson 2010].

Pressed juice inhibited the release of rhinovirus-induced pro-inflammatory cytokines (such as IL-1 and IL-6) and cytokines in human bronchial epithelial cells. Treatment of uninfected cells stimulated the release of various pro-inflammatory cytokines [Sharma 2006]. Additional experiments showed that the pressed juice stimulated the expression of genes involved in immune response including several chemokines and cytokines [Altamirano-Dimas 2007].

A butanol subfraction of a 70% ethanolic extract (not further specified) showed a dose-dependent (10-100 µg/mL) down-regulation of mRNA expression of chemokines (e.g. CCL3 and CCL8) and their receptors (e.g. CCR1 and CCR9) in human immature dendritic cells. Additional experiments showed an

up-regulation of genes involved in the control of cytokines (IL-8, IL-1β and IL-18) and of chemokines (CXCL 2, CCL 5 and CCL 2) within 4 h after treatment [Wang 2006, 2008].

An arabinogalactan-protein isolated from pressed juice was identified as a stimulator of both the classical and alternative pathways of complement activation. Removal of the arabinose side chains resulted in a reduction of this effect [Alban 2002].

Cytotoxicity
High concentrations (≥ 2500 µg/mL) of lyophilized pressed juice were cytotoxic in the T-lymphocyte transformation test [Hoh 1990]. Furthermore, 100 µg of a polysaccharide fraction stimulated peritoneal macrophages and bone marrow macrophages to cytotoxicity against P-815 cells in the same manner as 10 units of macrophage activating factor (MAF). It also stimulated phagocytosis and interleukin formation [Stimpel 1984; Wagner 1985].

Antiviral and viral resistant activity
Incubation of mouse L-929 cells or HeLa cells with 20 µg/mL of a pressed juice preparation for 4-6 hours before viral challenge increased their resistance to influenza, herpes and vesicular stomatitis viruses by 50-80% for at least 24 hours. The presence of hyaluronidase eliminated this effect [Wacker 1978].

In the presence of DEAE dextran a lyophilisate of pressed juice at concentrations of 25-200 µg/mL exhibited antiviral activity against encephalomyocarditis and vesicular stomatitis viruses. No antiviral activity was observed with DEAE dextran or the lyophilisate alone [Orinda 1973].

A decoction and a 30%-ethanolic extract inhibited the intracellular propagation of $ECHO_9$ Hill virus in a monkey kidney cell culture [Skwarek 1996].

An aqueous extract (100 mg dried herb powder/mL) showed antiviral activity against 40 strains of herpes simplex virus (HSV-1 and HSV-2) which were either resistant or susceptible to acyclovir. The median ED50 was a 1:100 dilution (with a range of 1:50–1:400) for acyclovir-resistant strains of HSV-1 and a 1:200 dilution (with a range of 1:50–1:3200) for strains of HSV-2. For the acyclovir-suspectible strains of HSV-1 and HSV-2, the median ED_{50} of the extract was 1:100 and 1:200 respectively [Thompson 1998].

Wound healing activity
Fibroblast populated collagen lattice was used to study the influence of extracts on the collagen-contracting ability of mouse fibroblasts. An ethanolic extract (final ethanol concentration 65%) significantly ($p<0.05$) inhibited collagen contraction when added, at 10 µl or 30 µl per 2 mL of collagen gel, during preparation of the lattice. A corresponding amount of ethanol had no inhibitory effect. With increasing time between preparation of the gel and addition of the extract there was less inhibition of elongation of fibroblasts and of the process leading to collagen linking. No effect was observed when the extract was added one hour after gel formation [Zoutewelle 1990].

Hyaluronidase-inhibiting activity
Hyaluronidase-inhibiting activity has been demonstrated in a *Streptococcus mucosus* culture. Hyaluronidase-dependent decapsulation of the bacteria (through depolymerization of hyaluronic acid) was diminished by the addition of 0.1 mL pressed juice to 0.3 mL of the test solution [Büsing 1955].

Other effects
In high-throughput screening of CYP inhibition, an extract (50:1) mildly inhibited CYP3A4 activity with 7-benzyloxy-4-trifluoromethylcoumarin as the model substrate, but had mild inducing effects in the presence of resorufin benzyl ether. It had little effect on CYP2D6 but moderately inhibited CYP2C9 [Yale 2005].

Dodeca-2*E*,4*E*,8*Z*,10*E*/*Z*-tetraenoic acid isobutylamide inhibited the CYP enzymes 2C19, 2D9 and 3A4 (IC_{50} values: 18.9, 6.8 and 1.9 µg/mL respectively) as did dodeca-2*E*,4*E*-dienoic acid isobutylamide (IC_{50} values: 23.4, 10.1 and 5.2 µg/mL respectively); these alkylamides did not induce CYP1A2 inhibition [Modarai 2007].

The same compounds were shown to bind to the CB2 receptor more strongly than endogenous cannabinoids. Both alkamides (50 nM) up-regulated constitutive IL-6 protein expression to 130-160% of controls, while 500 nM of dodeca-2*E*,4*E*-dienoic acid isobutylamide inhibited expression. LPS-induced TNF-α, IL-1β and IL-12p70 were inhibited by 50 nM of the two alkamides in a CB2-independent manner [Raduner 2006].

Caffeic acid derivatives characteristic of *Echinacea* species protected collagen from free radical-induced degradation in a dose-dependent manner; the IC_{50} for cichoric acid was 16.5 µM [Maffei 1995].

In vivo experiments

Immunomodulating effects
Intravenous injection of rabbits with 0.5 mL of pressed juice, followed by a second injection 24 hours later, initiated leucocytosis after transient leucopenia [Heuschneider 1970]. As well as blood leucocytosis, a migration of bone marrow granulocytes into peripheral blood was demonstrated in rabbits following a single injection of 1.5 mL of pressed juice. Within 6 hours the number of ^{3}H-labelled lymphocytes had increased from 7% to 40% and granulocytes from 34% to 89% [Choné 1965].

In the carbon clearance test in mice, an ethanolic extract was used as a solution of 5 mg extract per 30 mL of normal saline. After oral administration of this solution at 10 mL/kg b.w., three times daily for 2 days, carbon clearance was increased by a factor of 1.5 compared to the control. A chloroform-soluble fraction was even more active (factor 1.6), while the water-soluble fraction was less active (factor 1.3) [Bauer 1989].

Similarly, an ethanolic tincture administered orally to mice at 0.17 mL/kg three times daily for 2 days, stimulated carbon clearance by a factor of 2.1 [Bauer 1989].

In a study in female mice, an extract (250 mg per mL of glycerine-water 1:1) was administered by gavage at dosages of 0.4 and 0.8 mL/kg/day. Following immunization with sheep red blood cells (SRBC), 4 days of treatment with the extract produced a significant ($p<0.05$) enhancement of humoral immune responses compared to controls. In further experiments, 8 days of treatment with the same extract (0.6 mL/kg/day), and SRBC immunisation after day 4, did not enhance the immune response, whereas 4 days of treatment (starting 1 hour after SRBC immunization) did result in enhancement of immune response [Freier 2003].

Daily oral administration of the herb (50 mg, providing 0.5 mg of cichoric acid/kg b.w.) to 12-month-old male rats for 8 weeks resulted in a significant ($p<0.05$) transient increase in total white blood cell counts during the first 2 weeks. IL-2 levels increased significantly ($p<0.05$) in weeks 3 to 8 with the maximal effect from week 4 to week 6. Differential white blood cell counts showed an increase in monocytes and lymphocytes, while the numbers of neutrophils and eosinophils decreased ($p<0.05$) [Cundell 2003].

The protective effects of dried pressed juice (not defined further) against radiation-induced leukopenia in mice were investigated by evaluation of changes in peripheral blood cell count and peripheral blood antioxidant activity. Intra-abdominal administration (360 mg/kg every other day for at least 3 weeks) followed by whole-body radiation (two Gy) led to reduced leukopenia ($p=0.06$), faster recovery of blood cell counts ($p<0.01$) and an increase in peripheral blood antioxidant activity ($p<0.05$) compared to untreated animals.

The treatment also activated macrophages to stimulate IFN-γ production in association with secondary activation of T lymphocytes, which resulted in a decrease in IgG and IgM production. Immunostimulation was more pronounced in CD4 and CD8 subsets when compared to helper T cells and suppressor T cells. The pressed juice eliminated free radicals produced by irradiation, reduced cytotoxicity and prevented radiation-induced impairment of immunity [Mishima 2004].

In piglets receiving either 1.8% dried flowers or 20 mg/kg/day of flavomycin in their diet for 6 weeks no significant differences from control animals were observed in feed intake, daily weight gain, blood cell count, enzymes or proliferation of lymphocytes. Treatment of adult pigs in two phases, with 1.5% of the flowers or 4 mL/day of pressed juice (from herb) in weeks 1-3, and 1.5% of flowers or 6 mL/day of pressed juice in weeks 7-9, resulted in significantly ($p<0.03$) better feed conversion in echinacea-treated animals, but no significant changes were observed in the other parameters determined for the piglets. Antibody production in response to Swine erysipelas vaccination was enhanced significantly ($p<0.05$) after the flowers or pressed juice supplementation compared to controls [Maass 2005].

In mice, a polysaccharide-enriched extract showed a significant ($p<0.05$) increase of Delayed-Type Hypersensitivity response after 24 and 48 h treatment compared to control. At 72 h the differences were not significant [Ghaemi 2009].

After oral administration of pressed juice (10, 30 or 100 mg/kg b.w. daily for two weeks) to BALB/c mice, a significant reduction of splenocyte proliferation and splenic natural killer cell activity ($p<0.05$) as well as a significant increase of CD^{4+} and CD^{8+} T lymphocytes in the blood ($p<0.05$) were found. Serum cytokine levels, including IL-6, IL-10, and IL-17, as well as the mRNA expressions of these cytokines in spleen ($p<0.05$) were restored [Park 2018].

Cichoric acid, polysaccharides and alkamides from the herb and root were administered orally to rats twice daily for 4 days. Phagocytic activity and the phagocytic index, as well as TNF-α and NO release after stimulation with LPS, dose-dependently increased in alveolar macrophages. Enhanced release of TNF-α and IFN-γ was observed in spleen macrophages stimulated with phorbol myristate acetate and ionomycin [Goel 2002b].

In a similar experiment, three dose levels of cichoric acid, polysaccharides and alkamides were administered orally to rats twice daily for 4 days. Alkamides at the highest dose level (12 µg/kg b.w. per day) significantly ($p<0.05$) increased the phagocytic activity of alveolar macrophages by 60% and enhanced the phagocytic index ($p<0.05$). Dose-dependent increases in NO release and TNF-α production by LPS-stimulated alveolar macrophages were also observed with the alkamides. No significant changes in these parameters were observed with the other compounds. None of the components had any effect on the release of TNF-α, IFN-γ or IL-2 by splenocytes [Goel 2002a].

Other effects

Double-circle incisions in the left flank of anaesthetized guinea pigs were treated daily with 0.15 mL of an ointment containing pressed juice and covered with surgical gauze. By the 6th and 9th days following surgery the wound areas were significantly smaller ($p<0.05$) in comparison with untreated controls [Kinkel 1984].

Three groups of 10 mice were administered i.p. injections on days 0 and 21. One group received injections of 100 µL of an inoculum containing 10^5 pfu of live UV-inactivated HSV-1 strain (positive control), a second received PBS (negative control) and a third 100 µg of a polysaccharide-enriched extract. In an ocular lethal challenge performed three weeks after the last injection, all mice received an application of $5 \times 10^{5.5}$ pfu of wild type HSV-1 strain to each eye. The median survival time was significantly ($p<0.05$) greater in the extract and positive control groups compared to negative control, with 90% of mice from the extract group surviving longer than 7 days [Ghaemi 2009].

Male wistar rats were randomly divided into four groups of 10 rats each. One group received an ethanolic extract (60%; standardised to 3.7% polyphenolic compounds) at 50 mg/kg p.o., once daily for 3 days, another group received the same extract at the same dose for 10 days, while two control groups received a standard diet. Sixteen hours after the last administration, rats were decapitated and the mRNA expression level of major CYP450 enzymes was analysed. After 10 days of treatment with the extract, a significant ($p<0.05$) inhibition of the expression of CYP3A1/2, a significant ($p<0.05$) induction of CYP1A1 and CYP2D1 and no effect on CYP2E1 was found as compared to control [Mrozikiewicz 2010].

Pharmacological studies in humans

In a randomized, double-blind, prospective study, 42 healthy male athletes were treated orally with 8 mL of a preparation containing 80 g of pressed juice per 100 g or a magnesium hydrogen phosphate + magnesium hydrogen citrate preparation (providing 43 mg of Mg^{2+}) or placebo daily for 28 days preceding a triathlon competition to investigate the effects on exercise-induced whole body reactions. Compared to placebo, the pressed juice markedly reduced sIL-2R (soluble interleukin 2 receptor) in urine before the competition and enhanced the exercise-induced decrease in serum sIL-2R; it also enhanced exercise-induced increases in urinary IL-6 and serum cortisol. There was no incidence of respiratory infection in the pressed juice group compared to 3 out of 13 in the magnesium group and 4 out of 13 in the placebo group [Berg 1998].

A randomized, double-blind, placebo-controlled study involving 48 healthy volunteers evaluated the ability of pressed juice to prevent experimentally-induced infections with rhinovirus type 39. The volunteers received 3 × 2.5 mL of either the pressed juice or placebo daily for 7 days before and 7 days after intranasal inoculation with the virus. Clinical symptoms of rhinorrhea, congestion, sneezing, coughing, sore throat, headache, malaise and chills were evaluated. Viral culture and serological tests were also carried out to check for the presence of rhinovirus infection. From laboratory evidence there was little difference between groups in rates of infection: 92% in the verum group and 95% in the placebo group. Colds developed in 58% of echinacea recipients compared to 82% of placebo recipients ($p=0.114$) [Sperber 2004].

Clinical studies

Several reviews and meta-analyses of clinical studies using echinacea preparations have been published. A general conclusion has been that the preparations tested in clinical studies vary greatly. Some have shown efficacy in the early treatment of colds, while prophylactic use has also been suggested [David 2019; Blumenthal 2007; Linde 2006; Schoop 2006; Caruso 2005].

Meta-analyses
A meta-analysis [Schoop 2006] was carried out using the data from three experimental placebo-controlled studies in which echinacea treatment was evaluated following intranasal inoculation of a rhinovirus to experimentally induce a type of common cold. In two of these investigations [Sperber 2004; Turner 2000] the verum medication was pressed juice from the aerial parts of purple coneflower, while in the third study [Turner 2005] an extract from narrow-leaved coneflower (Echinacea angustifolia) was used. Although the individual studies had been unable to demonstrate significant superiority of the verum treatments, the larger sample size arising from pooled data revealed that the likelihood of experiencing a clinical cold was 55% higher under placebo than under echinacea treatment ($p<0.043$). The difference in total symptom scores between groups did not reach significance. This meta-analysis suggested that, in comparison with placebo, standardized extracts of coneflower were effective in the prevention of symptoms of the common cold after clinical inoculation of rhinoviruses.

A larger meta-analysis [Shah 2007] evaluated the data from 14 randomized, placebo-controlled studies in which a variety of echinacea-containing products had been used: 7 with *E. purpurea*, 1 with *E. angustifolia*, 1 with *E. pallida*, 4 with combinations of *Echinacea* species and one in which the type of echinacea was not specified. The data encompassed 1356 participants for the incidence and 1630 participants for the duration of common colds. Echinacea was found to significantly decrease the odds of developing a common cold by 58% ($p<0.001$) and the duration of colds by 1.4 days ($p=0.01$). A subgroup analysis on the data from 5 studies in which pressed juice from fresh purple coneflower herb was used indicated similar reductions in patients' odds to those in the overall analysis ($p=0.0009$) [Sperber 2004; Schulten 2001; Berg 1998; Hoheisel 1997; Schöneberger 1992].

Systematic review
A systematic review assessed the data from clinical studies in which preparations of purple coneflower had been used: 7 with pressed juice from purple coneflower aerial parts, 2 with an extract from various plant parts and 1 with a tincture made from 80% aerial parts and 20% root. The authors found some evidence that preparations based on the aerial parts of purple coneflower are effective for the early treatment of colds in adults, but the results were not fully consistent [Linde 2006].

Controlled studies
In a randomized, double-blind prospective study, 108 patients with a history of more than 3 colds or respiratory infections in the preceding year were treated daily for 8 weeks with 2 × 4 mL of either a preparation containing pressed juice (n=54) or placebo (n=54). During the treatment period 65% of patients in the verum group and 74% in the placebo group had at least one cold or respiratory infection. The average number of colds or respiratory infections per patient and the median duration of these ailments were 0.78 and 4.5 days respectively in the verum group compared to 0.93 and 6.5 days in the placebo group. Within a subgroup of 66 patients (29 verum, 37 placebo) who were especially susceptible to infections (T4/T8 cell ratio < 1.5), verum treatment reduced the average duration of infections by 29% to 5.34 days, compared to 7.54 days in patients given placebo. Although the incidence, duration and severity of colds and respiratory infections tended to be lower in the verum group, none of the results reached statistical significance [Schöneberger 1992].

In a randomized, double-blind, placebo-controlled study, 120 patients with initial symptoms of acute, uncomplicated upper airways infections were treated orally for up to 10 days with either a preparation containing 80 g of pressed juice per 100 g, at a dosage of 20 drops every 2 hours for the first day and thereafter three times daily (n = 60), or placebo (n = 60). The time taken to improvement was significantly shorter in the verum group ($p<0.0001$). In the subgroup of patients in whom common colds developed, the average time to improvement was 4 days with the expressed juice preparation (n=24) compared to 8 days with placebo (n=36) [Hoheisel 1997].

In a similar randomized, double-blind, placebo-controlled study, 80 patients with common cold were treated orally with 2 × 5 mL of pressed juice or placebo daily over a period of 10 days. The patients documented their symptoms and the intensity of symptoms in a daily questionnaire and the effect of treatment was assessed by the modified Jackson score. From intention-to-treat analysis the pressed juice reduced the median number of days of illness to 6, compared to 9 in the placebo group. Per-protocol analysis confirmed this result. The results were clinically relevant and statistically significant ($p=0.0112$ and 0.0180 for intention-to-treat and per-protocol analyses respectively) [Schulten 2001].

In a double-blind, placebo-controlled study, 282 healthy volunteers (aged 18-65 years) with a history of two or more colds in the previous year were randomized to receive either placebo or a 40%-ethanolic extract prepared from various parts of fresh purple coneflower plant and standardized to provide 1.0, 10.0 and 100 mg of alkamides, cichoric acid and polysaccharides respectively in a 4 mL dose. From the onset of symptoms of a cold, the volunteers were instructed to take 10 × 4 mL doses on the first day and 4 × 4 mL doses on each of the next six days. A total of 128 subjects contracted a common cold during the study, 59 in the verum group and 69 in the placebo group. In those who completed the study (n=111) the total daily symptom scores were 15.9 in the verum group and 20.7 in the placebo group, a significant ($p<0.01$) 23% lower in the verum group. The response rate to therapy was better in the verum group throughout the entire treatment period [Goel 2004].

The effect of the same preparation on immune response during common cold was evaluated in a subsequent randomized, double-blind, placebo-controlled study. Each dose of 5 mL of the 40%-ethanolic extract contained 1.25 mg of alkamides, 12.5 mg of cichoric acid and 127.5 mg of polysaccharides. Volunteers (n=150) aged 18 to 65 years, with a history of two or more common colds within the previous year, were recruited and instructed to start treatment from the onset of two symptoms of common cold, one being rhinitis. Treatment commenced with 8 × 5 mL doses on the first day, spaced equally throughout the day, followed by 3 × 5 mL doses on each of the next six days. At the time of recruitment and on days 3 and 8 of the cold fasting blood samples were collected in the morning. During the treatment period the volunteers were asked to complete a daily log, assessing the severity of their symptoms on a 4-point scale. Sixty-two volunteers contracted a common cold and completed the trial (26 verum and 36 placebo). Compared to the placebo group, a significant ($p<0.05$) decline in daily symptom score was evident in the verum group from day 3 onward, for the rest of the observation period. Significant increases were observed in the numbers of circulating total white blood cells, monocytes, neutrophils (all $p<0.01$ on day 3 compared to baseline) and NK cells. Furthermore, suppression of the cold-related increase in superoxide production by neutrophils, leading to a reduction in free radical generation, was observed in the later part of the common cold [Goel 2005].

Another double-blind, placebo-controlled study evaluated the efficacy of purple coneflower herb in upper respiratory tract infections (URTIs) in healthy children aged 2-11 years. The

participants were randomized to receive either dried pressed juice (31.5-53.6:1, in an alcohol-free syrup) or placebo during up to 3 URTIs over a 4-month period, with treatment to be started at the onset of symptoms and continued throughout the infection, for a maximum of 10 days. During URTIs children aged 2-5 years received 2 × 3.75 mL of the syrup per day (equivalent to 175 mg of dried pressed juice), while those aged 6-11 years received 2 × 5 mL per day. The primary outcome variables were duration and severity of symptoms, and adverse events recorded by parents; secondary variables included peak severity of symptoms, number of days of peak severity, number of days of fever, and overall assessment of severity of symptoms by the parents. Overall compliance was reported to be 80%. Data were analysed on 707 URTIs, 337 treated with echinacea and 370 with placebo, occurring in 407 children. The median duration of a URTI was 9 days.

No statistically significant differences were found in the duration of URTIs. However, an unexpected finding of the study was confirmed by a secondary analysis. Among 401 children experiencing at least one URTI, 55.8% of the children receiving purple coneflower herb developed a second URTI compared to 69.2% in the placebo group. This 28% reduction in risk of a subsequent URTI was significant (p = 0.01) [Taylor 2003; Weber 2005].

In a further randomized, double-blind, placebo-controlled study, patients received either 3 × 100 mg of a freeze-dried pressed juice in capsules (n=63) or placebo (n=65) daily, from the self-reported onset of common cold until the symptoms were relieved, or for up to 14 days. Symptoms such as sneezing, nasal congestion and discharge, headache, sore throat, cough or muscle aches were rated daily by the patients in a 4-point severity score system. No significant differences between verum and placebo groups were observed in total or individual symptom scores [Yale 2004].

Open studies
In a retrospective open study of 170 patients, intramuscular injection of 1-2 mL of diluted pressed juice (equivalent to 100-200 mg of pressed juice) on three successive days for the treatment of pertussis was comparable to antibiotics alone or in combination therapy. In a group of 63 patients treated only with the pressed juice 35% improved within 5 days of treatment and 81% within 10 days, whereas only 10% in a group of 30 patients treated with antibiotics alone improved within 5 days and 46% within 10 days. Out of a group of 77 patients treated with antibiotics plus intramuscular pressed juice, 9% improved within 5 days of treatment and 53% within 10 days [Baetgen 1984].

Similar results were obtained in a comparative retrospective open study of 1280 patients suffering from bronchitis. Results in a group treated only with pressed juice (intramuscularly, same dosage as in the previous study [Baetgen 1984]) were better than those in groups treated with antibiotics alone or with antibiotics plus intramuscular pressed juice [Baetgen 1988].

In an open comparative study involving 203 patients suffering from recurrent vaginal candidiasis, all patients were treated for 6 days with locally applied antifungal cream containing econazole nitrate. In addition, groups of patients received pressed juice for 10 weeks: 2 mL subcutaneously twice weekly (n=20); 2 mL intramuscularly twice weekly (n=60); 0.5-2 mL intravenously twice weekly (n=20); or 30 drops orally three times daily (n=60). Cell-mediated immunity, measured by an intracutaneous test with recall antigens before and 10 weeks after the start of treatment, showed significant improvement over this period in patients receiving the pressed juice. In the control group, patients (n=43) treated only with econazole nitrate had a very high relapse rate of 60.5% within 6 months, while adjuvant immunostimulation with the pressed juice significantly reduced relapse rates to 5-17% depending on the mode of administration [Coeugniet 1986].

Positive results were reported from clinical evaluation of 4598 patients with skin disorders, such as wounds, eczema, herpes simplex and burns, after topical application several times daily of an ointment containing pressed juice. Healing was achieved in 85% of cases [Bauer 2007].

Pharmacokinetic properties
A single oral administration of dodeca-2*E*,4*E*,8E,10*E*/*Z*-tetraenoic acid isobutylamides (tetraenes) to male Sprague-Dawley rats (2.5 mg/kg) resulted in rapid absorption (T_{max} 15 minutes) and distribution in the liver and brain tissues within 8 minutes. The maximum amounts of the tetraenes, calculated as $AUC_{0-\infty}$, in different brain parts, plasma and liver were 1764 to 6192, 794 and 1254 min x ng/mL respectively. $T_{1/2}$ was 1 and 4 hours in plasma and brain respectively [Woelkart 2007].

Preclinical safety data

Single dose toxicity
Single oral or intravenous doses of pressed juice caused no toxicity in rats or mice at the maximum administrable dose. The LD_{50} in rats is therefore over 15,000 mg/kg orally and over 5,000 mg/kg intravenously; and in mice, over 30,000 mg/kg orally and over 10,000 mg/kg intravenously [Mengs 1991].

Repeated dose toxicity
After oral administration of 0, 800, 2400 or 8000 mg/kg of pressed juice daily for 4 weeks to male and female rats, no relevant differences between the groups were evident from laboratory or necropsy results [Mengs 1991].

Effects on offspring
Female pigs (sows) received 0%, 1.2% or 3.6% of purple coneflower dried flowers in their diet from day 85 to day 110 of gestation and 0%, 0.5% or 1.5% up to day 28 of lactation, while a control group received alfalfa meal supplementation. No significant differences were found between groups with regard to feed intake, body weight, body temperature, plasma enzymes, blood cell count or proliferation of lymphocytes in sows and piglets. Colostrum composition was unaffected, as was daily weight gain and performance of the suckling piglets during lactation and a further 4-week observation period [Maass 2005].

Mutagenic potential

In vitro experiments
No significant increase in revertant numbers was observed at concentrations of up to 5000 µg per plate when preparations containing pressed juice were tested in *Salmonella typhimurium* strains TA 98, TA 100, TA 1535, TA 1537 and TA 1538, with or without S-9 metabolic activation [Mengs 1991].

The same preparations produced no statistically significant increase in the frequency of mutations in the mouse lymphoma assay at concentrations up to 5000 µg/mL, with or without S-9 metabolic activation [Mengs 1991].

There was no evidence of a clastogenic effect in human lymphocyte cultures with the lyophilized product at concentrations of up to 5000 µg/mL, with or without S-9 metabolic activation [Mengs 1991].

No significant differences were observed in the frequency of morphologically transformed colonies between controls

and groups of Syrian hamster embryo (SHE) cells treated with a preparation of lyophilized pressed juice at 5-55 µg/mL, equivalent to 80-880 µg of pressed juice per mL. Benzo[*a*]pyrene positive controls showed significant increases in malignant transformed cells [Mengs 1991].

In vivo experiments
A single oral dose of 25 g/kg of a preparation containing 80 g of pressed juice per 100 g and ethanol (22%) administered to mice did not increase the number of micronucleated polychromatic erythrocytes (PCE) compared to negative controls. Positive controls treated with cyclophosphamide did show a significant increase in micronucleated PCEs [Mengs 1991].

Clinical safety data

Several meta-analyses on clinical use and safety generally concluded that the use of echinacea is safe notwithstanding that several adverse reactions are reported. However, accurate information to evaluate these reports e.g. data on the echinacea species used, plant parts, type of extract, dosage and co-administration of other medicines are missing [Soon 2001; Mullins 2002; Huntley 2005; Gryzlak 2007; Freeman 2008; Kocaman 2008; Karsch-Völk 2014; Ardjomand-Woelkart 2016].

In controlled clinical studies involving oral treatment with purple coneflower herb preparations adverse event rates were comparable to placebo (<15%) and the preparations were very well tolerated [Brinkeborn 1999; Schulten 2001; Goel 2004]. In two studies no adverse events were observed in the purple coneflower herb group [Hoheisel 1997; Berg 1998]. Only one study reported a higher rate, with adverse events occurring in 20.4% of patients [Schöneberger 1992].

In children treated for URTIs with purple coneflower herb or placebo there was no overall difference between groups in the rate of adverse events except for the occurrence of rash: 7.1% in the verum group, 2.7% in the placebo group (p=0.008) [Taylor 2003].

Out of 63 patients with common cold receiving 3 × 100 mg daily of a freeze-dried pressed juice only a few reported adverse events, the most prevalent being dry mouth, headache and nausea [Yale 2004]

After topical application of an ointment containing pressed juice several times daily, adverse events were observed in only 2.3% of 4598 patients in an uncontrolled study. None were of a serious nature, being mainly pains, burning or itching [Viehmann 1978].

In a prospective controlled study involving 412 women, the pregnancy outcome was investigated following gestational exposure to (undefined) solid or liquid preparations of *Echinacea* (*angustifolia*, *purpurea* and in one case *pallida*). Of 206 women who used Echinacea products during pregnancy, 112 used them in the first trimester. In the Echinacea group 13 spontaneous abortions as well as 6 major malformations (4 of these occurring after exposure to Echinacea in the first trimester) were reported compared to 7 spontaneous abortions and 7 major malformations in the control group. No statistical difference was seen in terms of pregnancy outcome, delivery method, maternal weight gain, gestational age, birth weight or fetal distress [Gallo 2000].

A systematic review of the evidence from echinacea use during pregnancy and lactation concluded that echinacea (including *Echinacea purpurea*) is not teratogenic when used during pregnancy [Perri 2006].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ESCOP Scientific Committee
Board of Directors of ESCOP

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

ECHINACEAE PURPUREAE RADIX 2021

Purple Coneflower Root

DEFINITION

Purple coneflower root consists of the dried, whole or cut underground parts of *Echinacea purpurea* (L.) Moench. It contains not less than 0.5 per cent for the sum of caftaric acid ($C_{13}H_{12}O_9$; *M*r 312.2) and cichoric acid ($C_{22}H_{18}O_{12}$; *M*r 474.3) (dried drug).

The material complies with the monograph of the European Pharmacopoeia [Purple Coneflower Root].

CONSTITUENTS

The main characteristic constituents are:

Caffeic acid derivatives (0.6-2.8%), principally cichoric acid (2,3-*O*-dicaffeoyltartaric acid, 0.5-2.4%) and caftaric acid (2-*O*-caffeoyltartaric acid, 0.2-0.8%). Alkamides (0.5-0.7%), principally isomeric dodeca-2*E*,4*E*,8*Z*,10*E*/*Z*-tetraenoic acid isobutylamides [Bauer 1988a, 1989a, 2007; Perry 2000, 2001; Stuart 2003; Laasonen 2002; Pellati 2004; Bradley 2006; Cech 2006; LaLone 2009].

Polysaccharides such as fructans and glycoproteins [Beuscher 1990, 1995; Dalby-Brown 2005; Wack 2006].

Polyacetylenic compounds [Schulte 1967] and a small amount of essential oil (up to 0.1% V/m) [Heinzer 1988; Mazza 1999].

CLINICAL PARTICULARS

Therapeutic indications

Internal use
Adjuvant therapy and prophylaxis of recurrent infections of the upper respiratory tract (common cold) [Bauer 2007; Bräunig 1992; van Hellemont 1994].

Posology and method of administration

Dosage

Adult daily dose: 3 × 60 drops of a tincture (1:5, ethanol 55% V/V), 3 × 300 mg of dried root [Bauer 2007; Bräunig1992]; other equivalent preparations at comparable dosage.

Children: Proportion of adult daily dose according to age or body weight.

Method of administration
For oral administration.

Duration of administration
The duration of continuous treatment should not exceed 8 weeks.

Contra-indications
Known hypersensitivity to plants of the Asteraceae (*Compositae*).

As with all immunostimulants, not recommended in cases of progressive systemic disorders such as tuberculosis, diseases of the white blood cell system, collagenoses, multiple sclerosis and other autoimmune diseases, AIDS or HIV infections [Bauer 2007, Ardjomand-Woelkart 2016].

Special warnings and special precautions for use
If the symptoms worsen or high fever occurs during the use of the medicinal product, medical advice should be sought.

There is a possible risk of allergic reactions in atopic patients. These patients should consult their doctor before using echinacea.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
Although there is no evidence of harmful effects during pregnancy [Gallo 2000; Perri 2006], in accordance with general medical practice the product should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Echinacea can trigger allergic reactions in atopic patients.

Allergic reactions due to echinacea e.g. hypersensitive skin reactions are generally rare and mostly not serious [Ardjomand-Woelkart 2016].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Influence on immune functions
An ethanolic extract enhanced phagocytosis by 33% in the granulocyte smear test at a concentration of 10 µg/ml. Aqueous and lipophilic fractions from the extract showed immunostimulatory activity [Bauer 1989b].

In a simulated digestion protocol, a root powder increased cytokine secretion by murine macrophages. In contrast, extracts standardized to 4% of phenolic acids (such as chlorogenic and cichoric acids) were inactive with respect to macrophage activation [Rininger 2000].

Peritoneal macrophages were isolated from mice treated orally with a root powder at 100 mg/kg b.w. twice daily for 3 days. Western blot analysis of these macrophages after stimulation with LPS and interferon-γ showed a significant decrease of 57% in COX-2 expression ($p<0.05$) while iNOS expression was unaffected [Mattace Raso 2002].

A 50% ethanolic tincture partially or completely inhibited the release of pro-inflammatory cytokines such as IL-1 and IL-6 in a human bronchial epithelial cell line stimulated by rhinovirus type 14. Treatment of uninfected cells produced a different response and stimulated the release of pro-inflammatory cytokines [Sharma 2006].

Three extracts of fresh purple coneflower root (a 50% ethanolic tincture, a cold water infusion and a hot water infusion) were tested in four immune assays using human blood: secretion of TNF-α, IL-10 and IL-12 by monocytes, and proliferation of peripheral blood mononuclear cells. All three extracts significantly ($p<0.05$) stimulated TNF-α production, while effects on T-cell proliferation were minimal [Senchina 2005].
Other experiments with a 50% ethanolic extract demonstrated an increase in peripheral blood mononuclear cells and significantly ($p\leq 0.05$) increased IL-10 production [McCann 2007].

Significant ($p<0.05$) inhibition of prostaglandin E_2 production in LPS-stimulated RAW 264.7 mouse macrophages was shown for an ethanolic extract at a concentration of 15 µg/mL [LaLone 2007].

An alcoholic extract (not further defined; 10 to 200 µg/mL) concentration-dependently inhibited NO production and TNF-α release in LPS-stimulated RAW 264.7 macrophages. In RAW 264.7 macrophages incubated overnight in the extract and subsequently stimulated with salmonella, there was a significant ($p<0.037$ at 100-200 µg/mL) decrease in bactericidal activity as measured by an increase in internalized salmonella bacteria survival, but no significant effect on phagocytosis [Zhai 2007a].
Additional experiments with the same extract showed no direct inhibition of NO release. An immune blotting assay demonstrated that the extract (100 µg/mL) inhibited iNOS protein expression in LPS-treated macrophages. The extract (10-200 µg/mL) exhibited a concentration-dependent enhancing effect on arginase activity in RAW 264.7 cells incubated with 8-bromo-cAMP. None of the concentrations (19-200 µg/mL) had an effect on cell viability [Zhai 2009].

Various extracts (ethanolic 55% and 70%, water and ethyl acetate) inhibited IL-6 and IL-8 activity in both uninfected human epithelial cells and cells infected with rhinovirus (RV 14). The secreted IL-8 level was usually higher than IL-6 [Vimalanathan 2009].

Incubation of bone marrow-derived dendritic cells from mice with an aqueous extract (1:5 (w/v), 150 and 450 µg/mL) for 48 h resulted in an increase of the expression of MHC class II, CD86, and CD54 cell surface receptors and of the production of IL-6 and TNF-α [Benson 2010].

Seventeen ethanolic extracts (75%, 1:5 (m/V), root material of various ages and locations), as well as 4 alkylamides, were tested for their ability to inhibit the production of cytokines, chemokines, and PGE_2 from RAW 264.7 cells infected with the H1N1 influenza A strain PR/8/34. A dose-dependent suppression of the production of TNF-α and PGE_2 from infected cells was found for the alkylamides. In contrast, the extracts showed a range of effects from suppression to stimulation of inflammatory mediator production. Precipitation of the extracts with ethanol removed the stimulatory activity [Cech 2010].

A 75% ethanolic extract and its fractions inhibited the production of TNF-α, CCL1 and CCL5 by LPS-stimulated RAW 264.7 macrophages. The inhibition correlated with the content of alkylamides and other not specified constituents [Todd 2015].
The same extract (51±8.2 µg alkylamides/mg) and a fraction with a high alkylamide content (310±42 µg/mg) demonstrated significant inhibition ($p<0.05$, $p<0.001$ respectively) of de-granulation and calcium influx in A2318 stimulated RBL-2H3 cells [Gulledge 2018].

In concanavalin A-stimulated murine splenocytes, a glycerine extract (not further specified) increased TNF-production dose-dependently, while a modest increase of IFN-γ was found. No effect on production of IL-2 or cell survival was seen [Cadiz 2019].

A high molecular weight fraction (MW > 10,000 D) containing polysaccharides and glycoproteins enhanced the proliferation of mouse spleen cells; stimulated the production of cytokines such as IFN α/β in spleen cell cultures and IL-1, IL-6 and TNF-α in mouse macrophage cultures; increased immunoglobulin M production and the number of antibody-producing cells as well as NO production of macrophages. Incubation of this fraction with human monocytes also enhanced the production of IL-1, IL-6 and TNF-α [Beuscher 1990, 1995; Bodinet 1999].

Several alkamides isolated from dried roots inhibited COX-I and COX-II enzymes in the range of 36–60% and 15–46% respectively at 100 µg/mL. The inhibitory activity was compared to that of the positive controls acetylsalicylic acid, ibuprofen, naproxen, celecoxib and rofecoxib [Clifford 2002].

An alkamide fraction and individual alkamides inhibited LPS-mediated activation of murine macrophages with IC_{50} values of 6 µg/ml for the fraction and 3-25 µg/ml for individual compounds. Alkamides alone failed to activate the macrophages, while pre-incubation of the macrophages with the alkamide fraction before LPS stimulation reduced NO production [Chen 2005].

Further experiments showed that dodeca-2*E*,4*E*,8*Z*,10*Z*-tetraenoic acid isobutylamide and dodeca-2*E*,4*E*-dienoic acid isobutylamide bound to the cannabinoid CB2 receptor more strongly than endogenous cannabinoids. Both alkamides (50 nM) up-regulated constitutive IL-6 protein expression to 130-160% of the level seen in controls, while 500 nM of dodeca-2E,4*E*-dienoic acid isobutylamide inhibited expression. LPS-induced TNF-α, IL-1β and IL-12p70 were inhibited by 50 nM of the two alkamides in a CB2-independent manner [Raduner 2006].

Alkamides from a chloroform extract showed both partial and inverse agonist activity for CB1 receptors in [35S] GTPc S-binding experiments on rat brain membrane preparations. Compared with arachidonyl-20-chloroethylamide (ACEA) there was a very weak G-protein modulating activity. Upon co-administration with ACEA, several of the compounds inhibited the agonist [Hohmann 2011].

Antioxidant activity
Methanolic and ethanolic (1:10, 85%) extracts exhibited free radical scavenging and metal chelating activity [Sloley 2001; Hu 2000].

A sub-fraction, as well as isolated mixtures of alkylamides and caffeic acid derivatives from an 80% ethanol extract, showed a prolongation of the log phase of the Cu (II)-catalysed oxidation of human LDL. The maximum amount of oxidised LDL was the same in all cases [Dalby-Brown 2005].

In the DPPH assay, an 80%-methanolic extract, cichoric acid and caftaric acid showed EC_{50} values of 134 µg/ml, 6.6 µM and 20.5 µM respectively [Pellati 2004].

Caffeic acid derivatives such as cichoric acid protected collagen from free radical-induced degradation in a dose-dependent manner [Maffei Facino 1995].

Antiviral activity
A decoction and a 30% ethanolic extract inhibited the propagation of $ECHO_9$ Hill virus in monkey kidney cell cultures [Skwarek 1996].

An aqueous and two ethanolic (55% and 70%) extracts showed activity against rhinovirus, *Herpes simplex* virus and influenza virus [Hudson 2005].

A high molecular weight fraction (MW > 10,000 D) containing polysaccharides and glycoproteins exhibited antiviral activity against *Herpes simplex* virus and influenza virus [Beuscher 1995].

Wound healing activity
Fibroblast-populated collagen lattice was used to study the influence of an extract on the collagen contracting ability of C3H10T1/2 mouse fibroblasts. An ethanolic extract (65% V/V) dose-dependently inhibited collagen gel contraction when added at the time of preparation of the gel. With increase of elapsed time between gel preparation and addition of extract, there was less inhibition of elongation of fibroblasts and of the processes leading to collagen linking. No effect was observed when the extract was added one hour after gel preparation [Zoutewelle 1990].

Other effects
A hexane fraction of an ethanolic extract exhibited UV-mediated antifungal activity against *Candida* spp. and *Saccharomyces cerevisiae* [Binns 2000].

An ethanolic tincture (prepared from 95% herb and 5% root) inhibited the activity of the cytochrome P450 (CYP) enzymes 1A2, 2C19, 2D9 and 3A4 (IC_{50} values: 30.21, 60.87, 69.40 and 22.18 µg/ml respectively) [Modarai 2007].

A concentration-dependent (3-300 µg/mL) cytotoxic activity of a hexane extract in human pancreatic (MIA PaCa-2) and colon cancer (COLO320) cells was reported (IC_{50} 62.9 and 25.4 µg/mL respectively, $p<0.05$) [Chicca 2007].

An ethanolic extract (not further specified) and dodeca-2(*E*),4(*E*)-dienoic acid isobutylamide showed a significant accumulation of lipid droplets ($p<0.01$) and cellular triglycerides ($p<0.05$) in insulin-induced adipocyte differentiation of mouse 3T3-L1 pre-adipocytes as compared to control. A dose-dependent increase in expressions of peroxisome proliferator-activated receptor γ and C/EBPα in adipocytes was found as compared with control cells [Shin 2014].

Alkamides exerted anti-inflammatory activity in the 5-lipoxygenase assay [Müller-Jakic 1994; Wagner 1989]. A fraction consisting of ten polyunsaturated alkamides inhibited the effect of 5-lipoxygenase by 92.5% at 50 µM [Wagner 1989].

CYP enzyme-mediated degradation of alkamides was observed in human liver microsomes. Metabolism was dependent on both the structure of individual compounds and the combination in which they are present [Matthias 2005a].

In vivo experiments

Phagocytosis-stimulating effects
A purified glycoprotein fraction and polysaccharide fractions stimulated the activity of mouse macrophages in the carbon clearance test [Wagner 1985].

A 3-fold increase in phagocytosis in the carbon clearance test in mice was demonstrated after oral administration, at 10 ml/kg three times daily for 2 days, of a solution containing approx. 5 mg of an ethanolic extract in 30 ml of physiological saline. When chloroform and aqueous fractions of this extract were administered separately, the lipophilic fraction proved to be more active than the hydrophilic [Bauer 1989b, Bauer 1988b].

Cichoric acid as well as alkamide and polysaccharide fractions from ethanolic extracts were orally administered to rats twice daily for 4 days. Dose-dependent increases in phagocytic activity and the release of TNF-α and NO by the alveolar macrophages were found. At higher concentrations, enhanced release of cytokines (such as TNF-α and IFN-γ) was observed in rat spleen macrophages [Goel 2002].

Immunomodulating effects
Oral administration of an extract (0.45 mg/day, not further specified) to 7-week-old mice for 2 weeks resulted in a doubling of the number of natural killer (NK) cells and monocytes in the bone marrow and in the spleen [Sun 1999]. Oral administration

of the same amount of extract to ageing mice (15-16 months old) led to a 30% increase in the absolute number of NK cells and a 20% increase in the total functional activity of NK cells in the spleen [Currier 2000]. Oral administration of the extract to mice injected with leukaemia cells increased their survival time compared to controls [Currier 2001]. In leukaemic mice, the extract (0.45 mg/kg b.w.) in the diet increased the life span and the number of NK cells compared to controls [Currier 2002].

Mice were fed a normal diet or a diet supplemented with an extract (not further specified, 2 mg/mouse/day) from the age of 7 weeks until 13 months. At 10 months the verum group had a 100% survival rate compared to 79% in the control group, and at approximately 13 months of age the respective figures were 74% and 46%. Furthermore, the number of NK cells was significantly elevated in the verum group both in bone marrow ($p<0.01$) and in the spleen ($p<0.004$) [Brousseau 2005].

Oral administration of root powder to mice at 100 mg/kg b.w. twice daily for 3 days significantly ($p<0.01$) inhibited carrageenan-induced paw oedema. No significant changes were observed in haematological parameters, except for a significant ($p<0.01$) increase in granulocyte count [Mattace Raso 2002].

Oral administration of root powder (1.5% total polyphenols) to mice at 30 and 100 mg/kg/day for 14 days increased resistance of spleen lymphocytes to apoptosis. Both dose levels produced a significant decrease in Fas-Ag expression ($p<0.01$ at 30 mg/kg; $p<0.001$ at 100 mg/kg) and a significant ($p<0.001$) increase in Bcl-2 expression [Di Carlo 2003].

Male BALB/c mice received an alcoholic extract (130 mg/kg b.w. p.o. once a day for 7 consecutive days) and were immunized with sheep red blood cells 4 days prior to collection of immune cells. *Ex vivo* experiments with splenocytes showed significantly increased IL-2 and IFN–*g* production (both $p<0.035$) and with Con A stimulated splenocytes a significantly ($p=0.05$) increased IFN-γ production. The production of IL-1β was also significantly ($p<0.05$) increased [Zhai 2007b].

Mice received the same extract and treatment regimen in a further experiment, 3 days before collecting peritoneal exudate cells an inflammatory cell response was induced (3% protease peptone i.p.). Incubation of these cells with and without LPS showed no significant differences in IL-1β and IL-10 production compared to control groups (no gavage or vehicle). A significant ($p<0.05$) decrease in NO production was seen at 4 hours, but not at 24 hours after infection [Zhai 2007a].

Stimulation of the cell defence mechanism
In mice, production of IL-1 and IL-6 was enhanced by intravenous doses (50, 100 and 500 µg/animal) of a purified high molecular weight fraction containing glycoproteins and polysaccharides [Beuscher 1995]. Oral administration of this fraction to mice significantly enhanced antibody production in Peyer's plaque cells [Bodinet 1999].

Other effects
A significant ($p=0.02$) reduction in prostate weight was observed when rats were given a 50% ethanolic extract at 50 mg/kg b.w. daily for 8 weeks. Blood analysis showed an increase in lymphocytes after 8 weeks, but no differences in neutrophils, eosinophils or monocytes [Skaudickas 2003].

Pharmacological studies in humans
In a double-blind study, 24 healthy male volunteers took 3 × 30 drops of an ethanolic extract or placebo daily for 5 days. By day 5 a significant increase of 120% in phagocytosis was observed in the verum group compared to 20% in the placebo group. The effect was transient and phagocytic activity returned to normal within 6 days [Jurcic 1989].

Clinical studies
Several reviews and meta-analyses of clinical studies using echinacea preparations have been published. A general conclusion has been that the preparations tested in clinical studies vary greatly. Some have shown efficacy in the early treatment of colds, while prophylactic use has also been suggested [Caruso 2005; Linde 2006; Schoop 2006; Blumenthal 2007; David 2019].

In a double-blind, placebo-controlled study 180 patients aged 18-60 years with influenza, randomized into three groups of 60, were given a tincture (1:5, ethanol 55%) at daily dosages corresponding to 450 mg or 900 mg of dried root, or placebo. After 3-4 days and 8-10 days there was no statistical difference in symptoms between the group taking the 450 mg dose and the placebo group. In contrast, the group taking the 900 mg dose showed a highly significant ($p<0.0001$) reduction in symptom score at both time points [Bräunig1992].

In a randomized, double-blind, placebo-controlled study, volunteers took 1 mL of an ethanolic extract (1:11 in 30% ethanol, n = 99) or placebo (n = 90), once daily on 5 days per week (Monday to Friday) for 12 weeks. The average time to occurrence of first upper respiratory tract infection was 69 days in the treatment group and 65 days in the placebo group. In the treatment group, 29% had at least one upper respiratory tract infection, with 37% in the placebo group [Melchart 1998].

Pharmacokinetic properties

Root extracts from two Echinacea species
Alkamides were rapidly absorbed and measurable in plasma from 9 healthy volunteers 20 minutes after ingestion of 4 tablets, each containing dry ethanolic extracts corresponding to 675 mg of purple coneflower root + 600 mg of narrow-leaved coneflower root and remained detectable for up to 12 hours. The maximum plasma concentration of total alkamides (average 336±131 ng eq/ml) was reached within 2.3 hours. Caffeic acid conjugates could not be identified in any plasma sample [Matthias 2005b].

Preclinical safety data
No data available on purple coneflower root.

Clinical safety data
Several meta-analyses on clinical use and safety have generally concluded that the use of echinacea is safe, notwithstanding that several adverse reactions have been reported. However, accurate information to evaluate these reports e.g. data on the echinacea species used, plant parts, type of extract, dosage and co-administration of other medicines are missing [Soon 2001; Mullins 2002; Huntley 2005; Gryzlak 2007; Freeman 2008; Kocaman 2008; Karsch-Völk 2014; Ardjomand-Woelkart 2016].

No adverse events were reported in a study in which groups of 60 patients with influenza received oral treatment daily for 10 days with a tincture at dosages corresponding to 450 mg or 900 mg of dried root [Bräunig1992].

In another clinical study, 10 out of 99 subjects who took 2 × 1 ml of a hydroethanolic extract daily for 12 weeks reported adverse effects compared to 11 out of 90 in the placebo group. None of the adverse effects were serious or required therapeutic action [Melchart 1998].

In a prospective controlled study, the pregnancy outcome was investigated following gestational exposure to (undefined) solid

or liquid preparations of *Echinacea (angustifolia*, *purpurea* and in one case *pallida*). In the group of 206 women who used echinacea preparations during pregnancy (112 in the first trimester), 13 spontaneous abortions and 6 major malformations (4 occurring after exposure to echinacea in the first trimester) were reported, compared to 7 spontaneous abortions and 7 major malformations in the matching control group of 206 women. There were no statistical differences between the study and control groups for any of the end points analysed: pregnancy outcome, delivery method, maternal weight gain, gestational age, birth weight or fetal distress [Gallo 2000].

A study involving 12 healthy non-smoking volunteers assessed the effects of a root extract (not further specified) on the activity of CYP1A2 (substrate: caffeine), CYP2C9 (substrate: tolbutamide), CYP2D6 (substrate: dextromethorphan) and CYP3A (substrate: midazolam). After a control phase during which the volunteers received a single dose of each substrate orally (and midazolam also intravenously on a different day), 4 × 400 mg of the extract was taken daily for 8 days. After six days the substrates were administered and blood and urine samples were collected as during the control phase. The extract reduced the oral clearance of substrates of CYP1A2, but not of substrates of CYP2C9 or CYP2D6, and it selectively modulated the catalytic activity of CYP3A at hepatic and intestinal sites [Gorski 2004].

A systematic review of the evidence from use of echinacea during pregnancy and lactation concluded that echinacea (including *Echinacea purpurea*) is not teratogenic [Perri 2006].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books*, ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009,* but are not available online for copyright reasons.

After purchase of a single monograph*,* the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-kB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-b	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

EPILOBII HERBA

2024

Willow herb

DEFINITION

Willow herb consists of the whole or cut dried aerial parts of *Epilobium parviflorum* Schreb (syn. *Chamaenerion parviflorum*) and *E. angustifolium* L (syn. *Chamaenerion angustifolium*) (Onagraceae) collected before or during flowering time.

The materials comply with the monograph of the Czech Pharmaceutical Codex [Epilobii herba 1993; Kartnig 2014].

CONSTITUENTS

For *E. angustifolium* and *E. parviflorum* the main characteristic constituents are:

- Tannins and related compounds (4% to more than 10%), mainly oenothein B, oenothein A (dimeric and trimeric macrocyclic ellagitannins), tri-, tetra-, and penta-*O*-galloylglucose [Wichtl 2016; Granica 2014; Kartnig 2014].
- Flavonoids (1-2%): kaempferol, quercetin, myricetin, and their glycosides (e.g. kaempferol-3-*O*-rhamnoside, quercitrin, isoquercitrin, quercetin-3-*O*-glucuronide, myricitrin) [Slacanin 1991; Wichtl 2016; Granica 2014; Kartnig 2014; Monschein 2015].
- Phenolic acids and their derivatives: e.g. chlorogenic acid, neochlorogenic acid, coumaroylquinic acids, cinnamic acid, caffeic acid, ferulic acid, gallic acid and ellagic acid [Hevesi Toth 2009a; Ruszová 2013].
- Steroids (ca. 0.4%) and triterpenes (ca. 1.5%): e.g. cholesterol, campesterol, β-sitosterol, ursolic and oleanolic acid, pomolic acid [Wichtl 2016; Frolova 2014; Granica 2014; Kartnig 2014; Kukina 2014].
- Other constituents: e.g. linoleic acid, palmitic acid, stearic acid, eicosenoic acid, behenic acid, arachidic acid [Wichtl 2016; Granica 2014; Kartnig 2014].

CLINICAL PARTICULARS

Therapeutic indications

For symptomatic treatment of mild micturition disorders related to benign prostatic hyperplasia, irritable bladder [Epilobii herba 1993; Wichtl 2016; Kartnig 2014].

In these indications, the efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adult dose
3-4 g daily as an aqueous herbal infusion in two divided doses [Epilobii herba 1993].

Method of administration
For oral administration.

Duration of use
No restriction.
If symptoms persist or worsen, medical advice should be sought.

Contra-indications
None known.

Special warnings and special precautions for use
All cases of difficulty in micturition require clarification by a physician and regular medical checks in order to rule out the need for other treatment, e.g. surgical intervention. Consultation with a physician is particularly necessary in cases of blood in the urine or acute urine retention.

E/S/C/O/P MONOGRAPHS

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
Not applicable.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Hormonal activity
In a screening study, an undefined aqueous extract of *E. parviflorum* inhibited 5α-reductase enzyme activity by 90% at 10 µL/mL [Lesuisse 1996].

Aromatase inhibitory activity was found to be 70% for oenothein A and 33% for oenothein B at 50 µM; aminoglutethimide was used as a positive control (37% inhibition at 50 µM). Against 5α-reductase, oenothein A had an IC_{50} of 1.24 µM and oenothein B an IC_{50} of 0.44 µM; finasteride was used as a positive control (IC_{50} = 5 nM) [Ducrey 1997].

Antiproliferative activity, enzyme and PSA secretion inhibitory activities
An undefined ethanolic extract of *E. angustifolium* was investigated using human prostatic epithelial cells (PZ-HPV-7) by MTT-assay. Cells were exposed to 19, 190, and 1900 µg of dry extract per mL medium. A significant ($p<0.05$) antiproliferative effect was observed at the highest concentration after 24 h (68% growth inhibition (microscopic cells count) and 43.6% (MTT viability assay)) and 48 h (67% inhibition (microscopic cell count) and 76.6% (MTT viability assay)) compared with untreated controls [Vitalone 2001].

Undefined extracts prepared from *E. angustifolium* (using water and organic solvents) showed inhibitory activity against ACE, neutral endopeptidase (NEP) and aminopeptidase N (APN) enzymes. The strongest inhibition in case of NEP activity was demonstrated by the 70% methanolic and ethyl acetate fractions with IC_{50} values reaching 10 µg/mL. Inhibition of APN and ACE was much weaker, with IC_{50} values of 80 µg/mL (APN-butanolic extract) and 150 µg/mL (ACE-ethyl acetate extract). Among the isolated compounds, oenothein B showed the highest inhibitory potency against NEP with an IC_{50} of 20 µM. Phosphoramidon was used as a positive control (IC_{50} 9 nM) [Kiss 2004].

The effects on cell proliferation and the induction of NEP of an aqueous extract (DER 1:10, lyophilized) of *E. angustifolium* herb were investigated in PC-3 prostate cells (expressing low levels of NEP) and SK-N-SH human neuroblastoma cells (expressing high levels of NEP). NEP activity was dose-dependently increased in PC-3 cells by 138, 150 and 166% when compared to control (100%) at concentrations of 25, 50, and 100 µg/mL respectively. Cell proliferation was inhibited in the PC-3 cells by 93, 83 and 69% at the same concentrations. The increase in NEP activity was greater in the naturally higher NEP expressing SK-N-SH cells, increasing by 139, 309 and 2679% respectively, with reductions in cell proliferation of 84, 80 and 74% respectively. These improvements are stated as being significant when compared to control values by the authors but without p values being specified [Kiss 2006a, Kiss 2006b].

Hormone dependent prostate cancer cells (LNCaP) were exposed to 20, 50 and 70 µg/mL of lyophilized aqueous extracts (DER 4-5:1, extraction at 40°C) prepared from *E. angustifolium* and *E. parviflorum*. The extract from *E. parviflorum* most potently reduced cell proliferation (IC_{50} 32.2 µg/mL). PSA secretion (expressed in ng of PSA per mL/mg protein) was reduced from 325.6 ng/mL (control) to 84.6 ng/mL by the *E. parviflorum* extract. The extract of *E. parviflorum* also reduced arginase activity to ~40 mUnits of urea/mg protein compared to control (~65 mUnits of urea/mg protein). In all three test systems the inhibition was significant ($p<0.05$) and concentration-dependent. Incubation of the cells with the same extracts resulted in concentration-dependent significant ($p<0.01$) increases in the proportion of late apoptotic cells compared to control; results indicated activation of the mitochondrial pathway [Stolarczyk 2013a; Stolarczyk 2013b].

LNCaP cells were exposed to oenothein B. Maximum inhibition of proliferation with an IC_{50} value of 7.8 µM, reduction of PSA secretion (IC_{50} 21.9 µM) and inhibition of arginase activity (IC_{50} 19.2 µM) were observed [Stolarczyk 2013b].

The main constituents (oenothein B, myricetin-3-*O*-rhamnoside and quercetin-3-*O*-glucuronide) of *Epilobium* species, and ellagitannins' metabolites (urolithins) were investigated for their effects on proliferation of LNCaP cells, and against PSA secretion and arginase activity. Flutamide was used as a positive control for LNCaP cell proliferation (IC_{50} 52.9 µM) and PSA secretion (IC_{50} 206.2 ng/mL). L-NAME was used as a positive control for arginase activity (IC_{50} 53.2 ng/mL) as flutamide was inactive. Among the tested compounds, the strongest antiproliferative activity was shown by oenothein B (IC_{50} 7.8 µM), while among urolithins, urolithin C proved to be the most active (IC_{50} 35.2 µM). Oenothein B reduced PSA secretion to 59.0 ng/mL (IC_{50} 21.9 µM) and urolithin C to 100.7 ng/mL. Oenothein B reduced arginase activity to 1.1 mUnits of urea/mg protein (IC_{50} 19.2 µM) [Stolarczyk 2013b].

A lyophilized *E. angustifolium* aqueous extract containing 15% oenothein B was tested on selected prostate cancer cell lines (PZ-HPV-7, LNCaP), hormone-independent prostate cancer cells (DU 145), and normal human skin fibroblast cells (NHDFs). Incubation with the extract (20, 50, 70 µg/mL) resulted in a concentration-dependent and significant ($p<0.05$ and $p<0.001$) reduction of proliferation of PZ-HPV-7 (~34% at 10 µM) and LNCaP (~12% at 10 µM) cells without affecting the viability of NHDFs. The proliferation of DU 145 cells was slightly inhibited (69% of control proliferation at a concentration of 50 µg/mL) [Piwowarski 2017].

Oenothein B at concentrations of 2 µM, 5 µM and 10 µM concentration-dependently and significantly reduced the proliferation of LNCaP cells (~19% at 10 µM; $p<0.05$ at 5 µM, and $p<0.001$ at 10 µM) and of PZ-HPV-7 cells (~33% at 10 µM; $p<0.05$ at 5 µM, and $p<0.001$ at 10 µM) without affecting the viability of NHDFs cells. The proliferation of DU 145 cells was not affected [Piwowarski 2017].

Anti-inflammatory activity
Anti-inflammatory activity of undefined aqueous (A) and ethanolic (E) extracts of *E. parviflorum* were tested in the COX-1 and COX-2 assay at a concentration of 250 µg/mL. Indomethacin was used as a positive control [20 µM (COX-1) and 200 µM (COX-2)]. Inhibition of COX-1- [58% (A) and 96% (E)] and COX-2- [<10% (A)

and 59% (E)] catalysed prostaglandin biosynthesis was observed [Steenkamp 2006].

An undefined aqueous-acetone (80% V/V) extract of *E. parviflorum* was investigated in a COX-inhibition assay. Reduction of LPS-stimulated PGE2-release of macrophages (IC_{50} 1.4 µg/mL) was comparable to that of the positive control indomethacin (IC_{50} 21 µM). The anti-inflammatory effect of the extract was also investigated in the TBARS-assay. The extract inhibited lipid peroxidation at concentrations over 0.20 mg/mL (IC_{50} 2.37 mg/mL). However, it seemed to be pro-oxidant at lower concentrations [Hevesi Tóth 2009b].

The effects of lyophilized aqueous extracts (DER 1:10, extraction at 40 °C) of *E. angustifolium* and *E. parviflorum* on inhibition of hyaluronidase and lipoxygenase activity and the release of elastase and myeloperoxidase, were investigated. Hyaluronidase and lipoxygenase were inhibited by both extracts with IC_{50} values of 3.3 and 24 µg/mL (*E. angustifolium*), and 4.0 and 28 µg/mL (*E. parviflorum*), respectively. Elastase release was inhibited by both extracts with an IC_{50} > 50 µg/mL, and myeloperoxidase release was inhibited by the extracts of *E. parviflorum* (IC_{50} > 50 µg/mL) and *E. angustifolium* (34 µg/mL). For oenothein B, the IC_{50} values were 1.1 µM for hyaluronidase, 15 µM for lipoxygenase and 7.7 µM for myeloperoxidase. Heparin (hyaluronidase inhibition: IC_{50} 62 µg/mL), fisetin (lipoxygenase inhibition: IC_{50} 180 µM), quercetin (elastase inhibition: IC_{50} 20 µM) and indomethacin (myeloperoxidase inhibition: IC_{50} 15.4 µM) were used as positive controls. All extracts significantly ($p<0.01$) attenuated LTB4 release. None of the tested extracts showed cytotoxicity at concentrations of 3.125–50 µg/mL on human skin fibroblast cells [Kiss 2011].

The elastase, tyrosinase and lipoxygenase inhibitory activities of an aqueous dry extract (DER 1:25) of *E. angustifolium* leaves were evaluated. EC_{50} values were found to be 42.7 µg/mL (elastase); 33.0 µg/mL (tyrosinase) and 0.6 µg/mL (lipoxygenase) [Onar 2012].

Immunomodulatory activity

Immunomodulatory activity of oenothein B was investigated using an interleukin-18 (IL-18) activation assay and the K562 chronic myeloid leukemia assay. In the IL-18 activation assay, human and bovine lymphocytes were exposed to 0, 10, 20 and 40 µg/mL of oenothein B, while in the K562 assay 20 µg/mL was used. Stimulation of innate lymphocytes (NK and various T cells) and enhancement of the production of interferon γ(IFNγ) by bovine and human NK cells alone and in combination with IL-18 were detected. Furthermore, oenothein B enhanced the production of IFNγ by human T cells.

In another study, the effect of age on the immunostimulation of T cells by oenothein B was tested in human and bovine T cells. Cells yielded from neonate, young and adult donors, could be stimulated by oenothein B. However, the production of certain cytokines (e.g. IL-2Rα, IFNγ) by T cells, in response to oenothein B treatment, was enhanced only in adults. In addition, oenothein B induced granulocyte macrophage colony-stimulating factor production in human adult T cells, but not cord blood cells [Ramstead 2012; Ramstead 2015].

Antioxidant activity

Analysis of the radical scavenging capacity of a hot water extract (not further specified) of *E. parviflorum* evaluated by the $ABTS^{\bullet+}$ assay resulted in an IC_{50} of 1.1 µg/mL [Arredondo 2004].

Five different water-soluble extracts, prepared from the aerial parts of *E. angustifolium* (not further specified), were screened in 6 assays [iron(III) to iron (II) reducing activity, iron(II) chelation activity, DPPH scavenging, ascorbate–iron(III)-catalyzed phospholipid peroxidation, non-site-specific as well as site specific hydroxyl radical mediated 2-deoxy-D-ribose degradation] for antioxidant and radical scavenging activity. Ascorbic acid and Trolox were used as positive controls. In all test-systems, such properties were detected. The potency of the two most active extracts may be explained by their relatively high content of phenolic substances, as determined by the Folin-Ciocalteu reagent method [Shikov 2006].

The antioxidant and radical scavenging capacities of extracts prepared from various parts (root, leaf and stalk) of *E. angustifolium* with 1 mol/L or 0.1 mol/L K_2HPO_4 (pH=7.0) were evaluated. SOD enzyme activity was detected only in the leaves (17.21 U/mg protein). The leaf extract also exhibited the highest GPX (11.07 U/mg protein) and CAT (11.20 U/mg protein) activities. Substantial differences in the levels of MDA, $O2^{\bullet-}$, $OH^{\bullet}$, GSH and total flavonoid content were observed between the plant parts. The highest quantities of GSH (0.291 µmol/mg protein) and flavonoids (62.45 mg/mg protein) were recorded in the leaf extract. The results obtained in the DPPH assay suggested that the radical scavenging capacity (95.57%) and the total reducing power obtained by FRAP assay (46.51 FRAP units) were the highest in the leaves relative to the other plant parts [Štajner 2007].

E. parviflorum and *E. angustifolium* aqueous acetone extracts (80% v/v; not further specified) have been evaluated with respect to their radical scavenging effect using the ABTS assay. Trolox (EC_{50} 7.96 µM) and ascorbic acid (EC_{50} 14.29 µM) were used as positive controls. The extracts demonstrated high radical-scavenging activity (*E. parviflorum*: EC_{50} 1.71 µg/mL; *E. angustifolium*: EC_{50} 2.17 µg/mL) [Hevesi Tóth 2009a].

The radical scavenging effect of an undefined aqueous acetone (80% v/v) extract of *E. parviflorum* was investigated. In the DPPH assay, the extract showed a stronger antioxidant activity (2 µM, calculated by the average molecular weight of the extract components (MW 331.07)) than the reference substances Trolox (4 µM) and ascorbic acid (5 µM) [Hevesi Tóth 2009b].

Lyophilized aqueous extracts (not further specified) of *E. angustifolium* (EA) and *E. parviflorum* (EP) were investigated for antioxidant activity by evaluation of ROS production in formyl-met-leu-phenylalanine (fMLP)- and 4β-phorbol-12β-myristate-13α-acetate (PMA)-induced human neutrophils, and for radical scavenging activity in the xanthine-xanthine oxidase assay. The extracts significantly reduced the production of ROS in the activated neutrophils with IC_{50} values of 5 and 30 µg/mL (EA), and 5 and 24 µg/mL (EP), showing no significant differences between the two species. For the radical scavenging activity, IC_{50} values of 5 µg/mL ($O_2^{\bullet-}$), 3.6 µg/mL (H_2O_2) and 25 µg/mL (HClO) for EA, and 4 µg/mL ($O_2^{\bullet-}$), 2.2 µg/mL (H_2O_2) and 33 µg/mL (HClO) for EP were determined. Oenothein B showed a radical scavenging activity with IC_{50} values 0.9 µg/mL ($O_2^{\bullet-}$), 0.7 µg/mL (H_2O_2) and 10 µg/mL (HClO) [Kiss 2011].

The antioxidant activity of a dried aqueous extract of *E. angustifolium* (not further specified) was measured using various methods. Superoxide radical scavenging activity of the extract was determined as EC_{50} 127.15 mg/mL (7.41 mg/mL for Trolox); hydroxyl radical scavenging activity was shown to be 2.64 mg/mL (2.34 mg/mL for ascorbic acid); DPPH activity was measured as 2.70 mg/mL (2.59 mg/mL for ascorbic acid); and ABTS activity was determined as 0.052 mg/mL (0.051 mg/mL for Trolox) [Onar 2012].

The total phenolic content (TPC) and the radical scavenging activities (RSA) (expressed as rutin equivalents) of *E. angustifolium* collected from various locations were investigated. Extracts were prepared from fresh and dried plant samples with 75% ethanol. It was observed that the TPC content and the RSA of the extracts prepared from the fresh plant were higher (TPC: 180.2-324.3

mg/g rutin equivalents; RSA: 238.6-557.1 mg/g rutin equivalents) than those yielded from the dried ones (TPC: 70.6-126.8 mg/g; RSA: 119.9-124.8 mg/g) [Kaškonienė 2015].

Antimicrobial activity
A dried ethanolic extract of *E. angustifolium* (not further specified) showed antimicrobial activity against *Klebsiella pneumoniae* and *Pseudomonas aeruginosa* with MIC values of 81 µg/mL and 162 µg/mL respectively. Moreover, the alcoholic extract inhibited the growth of the fungi, *Microsporum canis*, at 10 µg/mL. The action was cytocidal [Battinelli 2001].

E. coli growth was inhibited totally by an ethanol extract (125 µg/mL; not further specified) of *E. parviflorum*. However, the extract was less potent than the control compound, ciprofloxacin (0.1 µg/mL) [Steenkamp 2006].

A hot water extract of *E. angustifolium* root (not further specified) was tested against several fungal strains. Activity was observed against *Candida glabrata* and *C. lusitaniae* at concentrations of 25 and 50 mg/L respectively [Webster 2008].

Undefined extracts of *E. angustifolium* showed bacterial growth inhibitory activity in all tested strains of *Staphylococcus aureus*, *Micrococcus luteus*, *Escherichia coli* and *Pseudomonas aeruginosa*. The tested concentrations were not shown, but the results were comparable to or more effective than 250 µg/mL vancomycin or tetracycline [Bartfay 2012].

Anti-aging effect
A 75% isopropanol extract of *E. angustifolium* (DER 10:1) was investigated in a specific anti-aging (photoprotective) model by measuring luminol-enhanced chemiluminescence. The antioxidant capacity of the extract in this model was ~2000 µmol/L, compared with Trolox (~8000 µmol/L). Furthermore, the extract at 10 µg/mL revealed a protective effect ($p<0.05$) on the viability of serum deprivation-induced senescent normal human dermal fibroblasts (NHDF). The treatment also led to a reduction ($p<0.05$) in connective tissue growth factor gene expression levels. The extract (10 µg/mL) inhibited TIMP-1 and -2 (tissue inhibitor of matrix metalloprotease) production and completely inhibited Hyal-2 gene expression in UV-irradiated NHDF [Ruszová 2013].

In vivo experiments

Hormonal activity
The anti-androgen effect of a dried aqueous extract of *E. angustifolium* (DER 20:6.3) was investigated at 40 mg/kg/day p.o. for 20 days in intact and testosterone-stimulated, castrated male Wistar rats. An anti-androgenic effect was observed in the intact rats as demonstrated by a significant ($p<0.01$) inhibitory effect on the weight of seminal vesicles. A pro-androgenic effect was observed in castrated rats, with the extract inducing a significant ($p<0.05$) increase in the weight of prostate, seminal vesicles and levator ani muscle compared to castrated rats not given the extract [Hiermann 1997].

Antiproliferative activity
The antiproliferative effect of a lyophilized aqueous extract of *E. angustifolium*, containing 15% of oenothein B, was investigated in rats. The extract was administered orally to rats at doses of 50, 100 or 200 mg/kg b.w. per day for 80 days. On day 20 of treatment, rats were i.p. implanted with LNCaP prostate cancer cells.

In rats fed with a standard diet only, implantation with the LNCaP cells resulted in the occurrence of prostatic adenoma in 71% (5 out of 7) of the animals. A considerably lower incidence of prostatic adenoma was observed in rats administered the extract, with 13% (1 out of 8) of the animals developing a tumour at 50 mg/kg b.w., and 25% (2/8) in both the 100 mg/kg and 200 mg/kg groups [Piwowarski 2017].

Anti-inflammatory activity
The anti-inflammatory activity of aqueous extracts of *E. angustifolium* and *E. parviflorum* was investigated in two animal models of inflammation. The ratios of herbal substance to extract solvent were 1:50 and 1:30 respectively for a prostaglandin release in perfused rabbit ear model and the carrageenan-induced rat paw oedema model in female Sprague-Dawley rats. Oral administration of 1 mL of the *E. angustifolium* extract (corresponding to 33 mg/mL dry herb/100 g b.w.) significantly ($p<0.001$) attenuated rat paw oedema compared to control, and was comparable to indomethacin (2 mg/kg p.o.); while the *E. parviflorum* extract was inactive. Inhibition of release of pro-inflammatory prostaglandins was much greater in the *E. angustifolium* extract group (1.25, 2.5 and 5.0 mg/mL; calculated as equivalents to the herbal substance) than the *E. parviflorum* group (5.0 mg/mL) in the perfused rabbit ear model [Hiermann 1986].

The flavonoid myricetin-3-*O*-glucuronide, from a hot water extract of the leaves of *E. angustifolium*, exhibited a strong, concentration-dependent anti-inflammatory effect in the carrageenan-induced rat paw oedema model (ED_{50} 15 µg/kg for the flavonoid and 10 mg/kg for indomethacin) as well as in adjuvant arthritis as a chronic model of inflammation (18.1 and 20.6% inhibition on the left and right paw respectively at 150 µg flavonoid/kg; 18.0 and 19.4% inhibition for 3 mg/kg indomethacin) [Hiermann 1991; Hiermann 1998].

Analgesic activity
An ethanolic extract of *E. angustifolium* (not further specified) was tested for analgesic activity in the hot plate and writhing tests. Concentrations of 0, 47.5, 95, 190 and 380 mg/kg b.w. were applied s.c. to Swiss ICR (CD1) male mice. An analgesic effect was observed in the writhing test at 95 mg/kg ($p<0.05$), while at doses ≥190 mg/kg the activity was similar to that of lysine acetylsalicylate (300 mg/kg s.c.) [Tita 2001].

Effect on CYP isoenzymes
A standardized dried aqueous extract of *E. angustifolium* (0.91% flavonoids, 24.36% phenolic compounds, 0.09% sterols and 0.01% tannins), administered to rats at 40 mg/kg b.w./day p.o., significantly ($p<0.05$) inhibited the expression of CYP3A1 mRNA, whereas it had no significant effect on the genes encoding CYP7A1, after 21 days of treatment [Kujawski 2009]. In a similar study, concurrent administration of the same extract (100 mg/kg b.w./day) with testosterone to castrated male Wistar rats significantly ($p<0.01$) ameliorated the testosterone-induced increase in CYP3A1 mRNA [Kujawski 2010]. In a further similar study, administration of the same extract (100 mg/kg/day) significantly increased the RafA mRNA ($p=0.076$), Mapk1 and Mapk3 mRNA levels ($p<0.05$ for both) and augmented the mRNA level-increasing effect of testosterone [Kujawski 2014].

Pharmacological studies in humans

Photoprotective effect
The photoprotective effect of a carbomer (0.5%) gel containing 3% of an *E. angustifolium* extract [prepared with 75% V/V of isopropanol (ratio of dried herbal substance:extraction solvent 1:5), and dissolved in 80% of 1.3-butanediol (200 mg/mL)] was tested in eight healthy volunteers. The preparation or a control gel without the extract were applied 3 times/day for 14 days to the forearm. The erythema indices were determined 24 and 48 hours after a single UV exposure of 1.25-times of the minimal erythema dose. Erythema indices decreased significantly ($p<0.05$) in the verum group [Ruszová 2013].

Pharmacokinetic properties
No data available.

Preclinical safety data

Acute toxicity
In an acute toxicity experiment, the LD_{50} value of *E. angustifolium* extract for mice was established as 1.4 mg/kg b.w. s.c. after 24 h [Tita 2001].

Repeated dose toxicity
Hydroalcoholic extracts prepared from *E. angustifolium* and *E. parviflorum* were tested for cytotoxic activity in Wistar rats orally administered 1.5 mL of extract for 10 days. Neither extract exhibited cytotoxic effects in the brain, hypothalamic-hypophyseal-adrenal axis, liver, kidney, spleen and thymus of the rats. *E. angustifolium* extract had only a moderate influence on the increase of oxidoreductase levels in liver and kidneys [Roman 2010].

Mutagenicity and carcinogenicity
The potential genotoxic and mutagenic properties of pomolic acid, isolated from *E. angustifolium*, were investigated using the SOS chromotest and the Ames test. Neither pomolic acid nor its metabolites induced DNA modifications in *Salmonella typhimurium* (TA98 and TA102) and *Escherichia coli* (PQ37) cells [Frolova 2014].

Clinical safety data
In a phase II randomized, double-blind, placebo controlled clinical trial, 32 men with benign prostatic hyperplasia were treated with a combination preparation including *E. parviflorum* extract for 3 months. The preparation was well tolerated and there were no adverse reactions reported [Coulson 2013].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (well-established use) or on experience and historical use of that product (traditional use) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

EQUISETI HERBA

2018

Equisetum stem

DEFINITION

Equisetum stem consists of the whole or cut, dried sterile aerial parts of *Equisetum arvense* L.. It contains not less than 0.3 per cent of total flavonoids, expressed as isoquercitroside ($C_{21}H_{20}O_{12}$; M_r 464.4), calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Equisetum stem].

CONSTITUENTS

The characteristic constituents are flavonoids (0.2-0.9%) [Veit 1989; Veit 1991], silica (1.3 – 10%) [Piekos 1975, Bruneton 1999, Bisset 2001, Bye 2010], caffeic acid esters [Veit 1991a, Weidner 1991], styrylpyrone glucosides [Veit 1993, Veit 1995], sterols [D'Agostino 1984], essential oil [Radulovič 2006, Fons 2013] and thiaminase [Fabre 1993].

CLINICAL PARTICULARS

Therapeutic indications
Irrigation of the urinary tract, especially in cases of inflammation and renal gravel, and as an adjuvant in the treatment of bacterial infections of the urinary tract. Topically as a haemostatic [Ożarowski 1987, Classen 2015], for wound healing [Asgharikhatooni 2015]. In these indications, the efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adult daily dose for internal use: Decoction of 5-6 g in 600 mL water, divided into 2-4 portions per day with an additional amount of liquid [Ożarowski 1987]; 370 mg dry extract (4-7:1; water) 3 times daily [Classen 2015].
Topical use: 3% ointment of hydroalcoholic extract [Asgharikhatooni 2015].

Method of administration
For oral and topical administration.

Duration of use
If symptoms persist or worsen, medical advice should be sought.

Contra-indications
Known hypersensitivity to equisetum stem.

Special warnings and precautions for use
Equisetum stem should be used with caution in patients with oedema due to impaired heart function [Hiller 2009].

Interaction with other medicinal products and other forms of interaction
None reported.

Pregnancy and lactation
In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
Not known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

E/S/C/O/P MONOGRAPHS

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antibacterial activity
The antibacterial activity of an aqueous dry extract (not further specified) against *Escherichia coli* and biofilm formation was studied at concentrations of 0.125, 0.25, 1.0, 5.0, 10.0 and 20.0 mg/mL. Compared to 100% cell survival in the control group, the percentage of surviving *E. coli* cells incubated with the extract was reduced to 82% at 0.125 mg/mL and 50% at 20 mg/mL. *E.coli* biofilm formation was significantly ($p<0.05$) reduced by the extract at a concentration of 0.125 mg/mL [Wojnicz 2012].

The antimicrobial activity of the essential oil, prepared by hydrodistillation of dried equisetum stem, against *Escherichia coli*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Streptococcus enteritidis*, *Staphylococcus aureus*, *Aspergillus niger* and *Candida albicans* was studied using ampicillin and doxycyclin as positive controls. The results showed a broad spectrum and strong antimicrobial activity against all tested strains, similar to the positive controls [Radulović 2006].

The antimicrobial activity of a hydroalcoholic dry extract against *S. aureus*, *K. pneumoniae*, *P. aeruginosa*, *S. enteritidis*, *A. niger* and *C. albicans* was studied using ampicillin and nystatin as positive controls. The effect of 5 µg of the extract per disc was comparable to the activity of 30 µg of ampicillin or nystatin [Milovanović 2007].

Antioxidant activity
Examination of ethyl acetate, n-butanol and aqueous extracts (not further specified) showed that the highest total radical scavenging capacity towards DPPH radicals and NO was exhibited by the ethyl acetate extract (EC_{50}=2.4 µg/mL and 90 µg/mL respectively), and the lowest by the aqueous extract (EC_{50}=37 µg/mL and EC_{50}=333 µg/mL respectively). The *n*-butanol extract showed the highest total reducing power expressed by Ascorbate Equivalent Antioxidant Capacity (13.4 µg/mL) compared to the ethyl acetate and aqueous extracts (both 1.5 µg/mL) [Mimica-Dukic 2008].

The radical scavenging capacity of an aqueous extract (1 g of fresh plant material in 5 mL 0.1 mol/L K_2HPO_4) towards DPPH and NO radicals was 51% and 9% respectively, compared to control [Štajner 2006].

Anti-inflammatory effects
An extract (1 part of dry equisetum stem with 9 parts of 36% ethanol V/V; 0.05 to 0.8 µg/mL) demonstrated dose-dependent significant reductions in IL-2 cytokine production and proliferation of immunocompetent cells ($p<0.05$ to 0.001) [Gründemann 2014].

Activity on bone tissue
In a study to observe the effects of equisetum on bone marrow cells and on bacterial infection to which they are prone, various hydromethanolic (1:1) extracts (differentiated by length of extraction time - not further specified) were tested over 21 days on human bone marrow osteoblastic cells (hBMC) and hBMC cultured over hydroxyapatite disc. At day 21, there were a range of effects with a significant dose-dependent increase in the cell population and activity against *S. aureus* at 50 and 100 µg/ml for the shorter-term extract. Longer extraction times and higher doses did not convey such benefits: different levels of silica in the extracts were postulated as part of the explanation [Bessa Pereira 2012].

A hydromethanolic (1:1) dry extract (not further specified) at concentrations of 0.016 to 500 µg/mL in DMSO was tested on both non-stimulated and stimulated human peripheral blood mononuclear cells (PBMC), used as osteoclast precursor cells, or a co-culture of PBMC with human bone marrow osteoblastic cells (hBMC). The extract dose-dependently reduced osteoclast development and function, both in stimulated osteoclast precursor cell cultures and in the co-culture of osteoclastic and osteoblastic cells [Costa-Rodrigues 2012].

Antiproliferative activity
n-Butanolic, methanolic, ethyl acetate and aqueous extracts were investigated for their antiproliferative activity against the human cancer cell lines HeLa, HT-29 and MCF7. The activity was dependent on cell lines, type of extract and concentration. The ethyl acetate extract exhibited the greatest antiproliferative effect [Cetojević-Simin 2010].

In vivo experiments

Anti-inflammatory effects
A 50% hydroethanolic extract (not further specified) at 50 mg/kg b.w. significantly ($p<0.05$) reduced carrageenan-induced paw oedema in mice by 25% and 29% at 2 h and 4 h respectively after carrageenan administration. A dose of 100 mg/kg b.w. significantly ($p<0.05$) reduced paw oedema by 30% at only 2 h after carrageenan administration [Do Monte 2004].

Effects on central nervous system
Aged rats demonstrate significant impairments in short- and long-term retention compared to young animals. A study aimed to show whether equisetum could reverse this impairment. Wistar rats aged 80 weeks were treated with a 50% hydroethanolic dry extract (not further specified) at a dose of 50 mg/kg b.w. i.p. or saline for 8 weeks. A group of untreated 8 week old rats was used as a control. Long-term retention was significantly ($p<0.05$) improved and short-term retention somewhat improved after administration of the extract, while cognitive performance in a modified version of the Morris Water Maze was ameliorated. No differences were found between the three groups (young controls, aged controls, and treated animals) with regard to the open field and elevated plus maze tests [Dos Santos Jr. 2005a].

The same extract was studied in male Wistar rats at doses of 50, 100, 200 and 400 mg/kg i.p. in various test systems including the open field test, rota-rod, elevated plus maze, barbiturate-induced sleeping time and pentylenetetrazole seizures compared to control. The extract showed dose-dependent significant effects ($p<0.05$ to 0.01) in the open-field test, and at doses of 200 and 400 mg/kg b.w significantly ($p<0.01$) increased the number of falls in the rota-rod reducing the time of permanence in the bar, and also at these doses increased barbiturate-induced sleeping time by 46% and 74% respectively. In the pentylenetetrazole-seizure test, all doses significantly ($p<0.05$ to 0.01) increased the latency until the first convulsion, diminished the severity of convulsion, and protected animals from death. The 200 and 400 mg/kg doses significantly reduced the percentage of animals developing convulsion by 50% ($p<0.05$) and 25% ($p<0.01$) respectively. On the contrary, no effect was seen in the elevated plus maze test [Dos Santos Jr. 2005b].

The anxiolytic effects of petroleum ether, chloroform, ethanolic and aqueous extracts were studied in mice using the elevated plus-maze model. The ethanolic extract (50 and 100 mg/kg b.w. i.p.) had a comparable effect to diazepam, significantly ($p<0.05$) increasing the time-spent and the percentage of open arm entries. At 100 mg/kg it also prolonged the ketamine-induced total sleeping time and decreased the locomotor activity [Singh 2011].

Antidiabetic effect
A methanolic extract (not further specified) administered to diabetic rats at doses of 50, 100, 250 and 500 mg/kg b.w. p.o. for 5 weeks, significantly ($p<0.0001$) reduced plasma glucose levels compared to untreated controls. In comparison to 5 mg/kg b.w. of glibenclamide, no significant difference was observed. The urinary creatinine level in rats treated with the extract and with glibenclamide was significantly ($p<0.001$) higher compared to control, whereas the microalbumin level was lower [Safiyeh 2007a].

Diabetic rats were treated with *n*-hexane, dichloromethane or methanolic extracts (not further specified) for 5 weeks. The methanolic extract at doses of 50, 250 and 500 mg/kg b.w. showed a significant reduction ($p<0.0001$) of plasma glucose levels compared with untreated controls. The extract showed no significant difference compared to glibenclamide [Safiyeh 2007b].

The treatment of streptozotocin-induced diabetic rats with a methanolic extract (not further specified) at doses of 50 and 250 mg/kg b.w. p.o. or 5 mg/kg b.w. of glibenclamide for 5 weeks showed a significant ($p<0.0001$) hypoglycaemic effect. The histological examination showed a regeneration of the streptozotocin-induced necrosis of the pancreas by the extract comparable to glibenclamide [Safiyeh 2007c].

Wound healing effect
The effect of 5% and 10% equisetum ointments (not further specified) on dermal wounds in rats was studied. The groups treated with equisetum showed a significantly higher wound closure ratio, higher dermal and epidermal regeneration, angiogenesis and granulation tissue thickness after 14 days as compared to the untreated control groups ($p<0.05$) [Ozay 2010]. The same preparations were tested in the treatment of dermal wounds in streptozotocin-induced diabetic rats. The same parameters as in the previous study showed significant improvement in 14-days old wounds as compared to control ($p<0.05$) [Ozay 2013].

Pharmacological studies in humans

Diuretic effect
In a double-blind, randomized trial, the diuretic effect of a dry extract containing 0.026% of total flavonoids (not further defined) was investigated using a 3 phase cross over protocol. Six groups (n=6 each) of healthy male volunteers were alternately administered for 4 consecutive days with the extract at 300 mg 3 times daily, hydrochlorothiazide 25 mg/day and placebo (cornstarch 900 mg/day) with a 10 day washout period between treatments. Each group was given the treatments in a different order. The diuretic effect was assessed by monitoring the water balance (difference between fluid intake and excreted urine) over a 24 h-period. Diuretic activity was significantly ($p<0.001$) stronger than in the placebo group and equivalent to hydrochlorothiazide ($p=0.566$), without causing significant changes in the elimination of electrolytes [Carneiro 2014].

Wound healing effect
In a randomized, placebo-controlled, double-blind study, the effects of a 3% hydroalcoholic extract (not further specified) in an ointment on wound healing, reduction of inflammation and pain relief were examined in 108 nulliparous mothers after episiotomy. The effects of the treatment compared with the placebo ointment were assessed at 5±1 and 10±1 days post-episiotomy. Significant differences were observed between the treated and control groups for erythema at baseline ($p<0.04$) and 10 days after intervention ($p<0.001$), and for oedema at baseline ($p<0.002$) and 5 and 10 days after intervention ($p<0.001$ for both). Pain intensity had decreased on day 5 by 14% in the treated group and increased in the control group by 34%. On day 10, pain intensity was reduced by 86% and 13% in the treated and control groups respectively. The number of acetaminophen pills (0.5 g) used during the 10 day study period by treated and control groups were 6.8 ± 4.4 and 11.6 ± 7.1 respectively [Asgharikhatooni 2015].

Pharmacokinetic properties
No data available.

Preclinical safety data

Toxicity
The subchronic toxicity of powdered equisetum stem administered with the diet to female and male F344 rats was evaluated for 13 weeks. Significant alterations ($p<0.05$) were observed in haematological parameters including increased mean corpuscular haemoglobin (MCH) in males at a dose of 3.8 g as well as increased platelet count (PLT) and decreased MCH in the females at a dose of 7.9 g. Significant decreases ($p<0.01$) in serum calcium concentrations were observed at doses of 7.9 and 24.2 g in males. The intake did not significantly influence macroscopic and histopathological parameters or weight of organs [Tago 2010].

Oral administration of dried equisetum stem at doses of 30, 50 or 100 mg/kg b.w. for 14 days did not cause important changes in the morphology and hepatic function in rats [Baracho 2009].

Wistar rats at the age of 8 weeks (10) and 80 weeks (22) were treated with a hydroalcoholic dry extract (not further specified) at a dose of 50 mg/kg b.w. i.p. for 8 weeks. There was no toxicity observed during treatment [Dos Santos Jr. 2005a].

Clinical safety data
No data available.

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

FILIPENDULAE ULMARIAE HERBA 2015

Meadowsweet

DEFINITION

Meadowsweet consists of the whole or cut, dried flowering tops of *Filipendula ulmaria* (L.) Maxim. (= *Spiraea ulmaria* L.). It contains not less than 1 mL/kg of essential oil, calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Meadowsweet].

CONSTITUENTS

Flavonoids, up to 6% in the flowers, particularly spiraeoside (quercetin 4′-glucoside), and approx. 3-4% in the flowering herb, including hyperoside, other quercetin derivatives and kaempferol 4′-glucoside [Hörhammer 1955, 1956; Shelyuto 1977; Scheer 1987; Lamaison 1991, 1992; Poukens-Renwart1992; Fecka 2009].

Glycosides of salicylaldehyde (monotropitin = gaultherin), of methyl salicylate (spiraein) and of salicyl alcohol (isosalicin) (up to 0.5% in total) [Thieme 1965, 1966; Meier 1987a, 1987b, 1993].

Steam distillation of the dried flowers yields a small amount (0.2%) of volatile oil (arising from the phenolic glycosides during drying and storage), of which about 75% is salicylaldehyde [Kozhin 1971; Lindeman 1982; Meier1987b]. Previous findings, however, stated that such compounds are only present in fresh flowers [Piette 1981]; after steam distillation of fresh flowering tops, the proportion of salicylaldehyde in the oil was 36% [Valle 1988].

Ellagitannins (10-15%) derived from galloyl-4,6-hexahydroxydiphenoyl-β-D-glucose units, the major one being the dimeric rugosin D [Gupta 1982; Haslam 1982,1996; Meier 1993; Okuda 1993; Wichtl 1997, 2009; Fecka 2009].

The flowers also contain a heparin-like substance, which is bound to plant proteins in the form of a complex [Kudrjashov 1990, 1992].

CLINICAL PARTICULARS

Therapeutic indications

Filipendula is used as supportive therapy for the common cold [Schilcher 1992; Meier 1993; Wichtl 1997; Zeylstra 1998; Schulz 2001; Wichtl 2009]. Meadowsweet is also used to enhance the renal elimination of water [Decaux 1941; Leclerc 1976; Valnet 1976; Meier 1993; Wichtl 1997, 2009; Zeylstra 1998], although published scientific evidence does not adequately support this indication.

Posology and method of administration

Dosage
Unless otherwise prescribed, the daily dose as a tea infusion is:

Adults: 2-6 g of the drug daily [Mills 2000; Wichtl 2009].
Children 1-4 years of age: 1-2 g daily [Dorsch 1998].
Children 4-10 years of age: 2-3 g daily [Dorsch 1998].
Children 10-16 years of age: adult dose [Dorsch 1998].

Liquid extract (1:2), 3-6 mL daily; tincture (1:5), 7.5-15 mL daily [Mills 2000].

Method of administration
For oral administration.

Duration of administration
No restriction.

Contra-indications
Due to the presence of salicylates, the drug should not be used in cases of hypersensitivity to salicylates [Meier 1993; Wichtl 2009].

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported. The level of salicylate derivatives makes interaction with anticoagulant agents unlikely.

Pregnancy and lactation
No data available. In accordance with general medical practice, the products should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antimicrobial activity
Combined 70%-ethanolic and aqueous extracts (1 mL corresponding to 1 g of herb), tested at 5% in the culture medium, inhibited the growth of *Staphylococcus aureus haemolyticus*, *Streptococcus pyogenes haemolyticus*, *Escherichia coli*, *Shigella flexneri*, *Klebsiella pneumoniae* and *Bacillus subtilis* [Csedö 1993].

A tincture from the flowers (70% ethanol, diluted 1:10 and 1:25) inhibited the growth of *Staphylococcus aureus* and *S. epidermis* at both concentrations, and of *Proteus vulgaris* and *Pseudomonas aeruginosa* at the higher concentration only. No effect was seen with *E. coli* or *Klebsiella* [Hintz 1983].

Dried ethanolic extracts (96% and 40% V/V) showed antimicrobial activity at concentrations from 0.1 – 0.8 mg/mL in Gram-positive bacteria (*Staphylococcus aureus* and *Bacillus subtilis*). Higher concentrations were needed to inhibit growth of Gram-negative bacteria (0.6 – 6mg/mL; *Salmonella enteritidis* and *Escherichia coli*) and fungi (6 – 48mg/mL; *Penicillium expansum* and *Rhizopus arrhizus*). The 40% ethanolic extract contained higher amounts of phenolic compounds and showed better results in the inhibition of tested bacteria and fungi [Gniewosz 2013].

A methanolic extract showed a MIC_{50} of 0.08% on the Gram negative pathogens *Proteus vulgaris* and *Klebsiella pneumoniae* [Denev 2014]

Anti-inflammatory activity
Extracts (50% ethanolic) of meadowsweet flowers and leaves inhibited the activity of the proteolytic enzyme elastase by 100% and 92% respectively, measured by spectrophotometry using an amino acid-nitroanilide substrate and attributed to the tannin content of the materials [Lamaison 1990].

An aqueous, lyophilized extract of meadowsweet leaves inhibited prostaglandin biosynthesis from ^{14}C-arachidonic acid (i.e. inhibited cyclooxygenase) in bovine seminal vesicle microsomes by 36% at 0.2 mg/mL, a relatively low level of activity compared to 88% inhibition by indometacin at 2.8 µM. The same extract strongly inhibited PAF-induced exocytosis (and hence release of the enzyme elastase) in neutrophils from human peripheral blood by 93% at 0.25 mg/mL [Tunòn 1995].

An aqueous extract was incubated with human faeces to convert ellagitannins into urolithins by the gut microflora. Results of inhibition studies in monocyte-derived macrophages showed a significant decrease of TNF-α production. The most potent derivative urolithin A reached an inhibition of 29.2% ±6.2 ($p<0.05$) at 0.625 µM. Urolithin C significantly decreased Interleukin-6 production by 25.5% ±4 as well at 10 µM ($p<0.001$) compared to stimulated but untreated cells [Piwowarski 2014].

An aqueous extract as well as isolated constituents were investigated for their ability to inhibit production of inflammatory biomarkers in monocyte derived macrophages. Apigenin and quercetin significantly reduced the production of TNF-α in the stimulated cells at the highest concentration (50 µM) by 89% ±4 and 84% ±2 and of Interleukin-6 by 97% ±3 and 96% ±1, respectively ($p<0.05$). The extract, containing 3 µM quercetin, reduced production of TNF-α by 34% ±11, IL-1β by 45% and IL-6 by 16% ±11. [Drummond 2013].

Immunomodulatory activity
Dry extracts from meadowsweet flowers and herb exhibited strong inhibitory activity towards the classical pathway of the complement system, ethyl acetate (IC_{50}: 5.4 µg/mL) and methanolic (IC_{50}: 14.6 µg/mL) extracts of the flowers, and the methanolic extract (IC_{50}: 14.5 µg/mL) of the herb, being the most effective. As the ethyl acetate extract of the flowers retained its activity after treatment with skin powder, it was concluded that complement inhibitory activity of this fraction is not attributable to tannins [Halkes 1997a].

In the same series of experiments, meadowsweet dry extracts from flowers and herb prepared with ether, ethyl acetate, methanol or water inhibited luminol-dependent chemiluminescence (an indicator of the production of reactive oxygen species) generated by zymosan-stimulated human polymorphonuclear leukocytes (PMNs) with IC_{50} values of 66.3 µg/mL, 42.3 µg/mL, 39.8 µg/mL and 37.4 µg/mL respectively for the flower extracts and 81.9 µg/mL, 44.5 µg/mL, 59.5 µg/mL and 60.8 µg/mL respectively for the herb extracts. The extracts also inhibited T-cell proliferation, with IC_{50} values of 100.4 µg/mL, 173.9 µg/mL and 210.5 µg/mL respectively for ethyl acetate, methanol and aqueous extracts of the flowers, and 195.1 µg/mL, 150.0 µg/mL and 195.2 µg/mL respectively for ether, ethyl acetate and methanolic extracts of the herb [Halkes 1997a].

Various extracts of meadowsweet flowers were investigated for *in vitro* modulatory activity towards the classical pathway of complement activation. The highest inhibitory activity was found in the ethyl acetate extract (IC^{50}: 2.9 µg/mL), followed by the ether (IC^{50}: 9.8 µg/mL), light petroleum (IC^{50}: 12.0 µg/mL), methanol (IC^{50}: 12.8 µg/mL) and aqueous (IC^{50}: 53.5 µg/mL) extracts. A purified fraction from the ethyl acetate extract (constituents not identified) also showed strong inhibitory activity (IC^{50}: 0.46 µg/mL), even stronger than that of isolated flavonoids (of which quercetin was the most potent with an IC^{50} of 16.7 µg/mL) [Halkes 1997b].

A decoction of the flowers enhanced the growth-stimulating activity of mice peritoneal macrophages *in vitro* and *in vivo* [Bespalow 1992].

A decoction (1g/200 mL) was investigated for growth inhibition of non-small cell lung cancer (NCI-H460) cells. The anti-proliferative potential was measured by reduction of the percentage of bromodeoxyuridine positive cells. The treatment showed an effect on the cell cycle profile by increase of cells in G1 proliferation phase. The extract had no effect on programmed cell death but a significant increase of the protein p21 was found ($p<0.05$) [Lima 2014].

Antihistaminic effect
Four isolated ellagitannins (rugosin A, rugosin D, rugosin A methyl ester and tellimagradinin II) were tested for inhibition of human histidine decarboxylase which catalyses the formation of histamine from histidine. The inhibition constant values (Ki) of the non-competitive reaction ranged from 0.35-1µM, comparable with the potency of the substrate analogue inhibitor histidine methyl ester (Ki 0.46 µM) [Nitta 2013].

Affinity for proteins
Isolated rugosin D showed a high capacity for binding to bovine serum albumin (BSA), even higher than penta-O-galloyl-β-D-glucose, the tannin having the highest protein binding capacity in the simple galloyl-D-glucose series [46], whereas 1,2,3-tri-O-galloyl-4,6-hexahydroxydiphenoyl-β-D-glucose had a weaker effect and 2,3-di-O-galloyl-4,6-hexahydroxydiphenoyl-β-D-glucose a low effect [Beart 1985].

Antioxidant effect
A methanolic extract inhibited xanthine oxidase (XO) with an IC_{50} value of 6.2 µg/mL ± 0.6, compared to allopurinol and its main metabolite oxypurinol of 2.6µg/mL ±0.9 and 1.0 µg/mL ±0.2 respectively [Kazazi 2009].

In vivo experiments

Anticoagulant and fibrinolytic effects
A heparin-like complex found in meadowsweet flowers showed some anticoagulant and fibrinolytic properties after intramuscular and intravenous administration to animals, the effect being neutralized by protamine sulphate [Kudrjashov 1990, 1991].

Intestinal effects/effects on gastric ulcers
Orally administered decoctions of meadowsweet flowers (1:10 and 1:20) at doses of 0.5 or 2.5 mL/100 g respectively reduced the formation of stomach lesions induced by fixation, immobilisation or subcutaneous injection of reserpine to rats and mice. The decoctions also prevented acetylsalicylic acid-induced lesions of the stomach and promoted healing of ethanol-induced stomach lesions in rats [Barnaulov 1980].

An ethanolic spissum extract from meadowsweet, administered to mice (50-1000 mg i.p.), rats (2500 mg/kg orally) and rabbits (15-30 mg/kg i.v.) as a 5% aqueous solution and a decoction (1:20), showed a positive effect on the permeability of vessels provoked by histamine in the trypan blue test system [Barnaulov 1977].

Quercetin-3'-glucoside from meadowsweet, orally administered as a dose of 0.5 mL of a 5% solution per 10 g b.w., reduced by 50% the occurrence of serious lesions of the rat stomach provoked by immobilisation and intraperitoneal injection of reserpine (2.5 mg/kg) [Barnaulov 1984].

CNS effects
In various animals, a 5% aqueous solution of an ethanolic spissum extract and a decoction (1:20) from meadowsweet showed suppressive effects on the central nervous system, such as reduction of motor activity and rectal temperature, myorelaxation and potentiation of the activity of narcotic agents, and prolongation of the life time of mice in closed cages [Barnaulov 1977].

Anticarcinogenic effects
Long-term oral administration of a decoction of meadowsweet flowers inhibited the growth of brain and spinal cord tumours induced by transplacental administration of N-ethyl-N-nitroso-urea in rats. It did not affect the development of cervical and vaginal tumours induced by intravaginal application of 7,12-dimethylbenz[*a*]anthracene in mice but, when applied intravaginally, the decoction inhibited cervical and vaginal carcinogenesis induced by this compound. Tubal oral administration of the decoction suppressed the growth of transplanted sarcoma-180 as well as the growth and metastasis of transplanted Lewis' carcinoma in mice [Bespalov 1992].

Local administration of a decoction of meadowsweet flowers resulted in a 39% decrease in the frequency of squamous-cell carcinoma of the cervix and vagina induced in mice by 7,12-dimethylbenz[*a*]anthracene treatment [Peresun`ko 1993].

Isolated rugosin D was administered as a single i.p. dose of 10 mg/kg b.w. to 6 female mice; 4 days later and at weekly intervals thereafter for 60 days the mice were injected intraperitoneally with 10^5 sarcoma-180 tumour cells. Antitumour activity was calculated as the percentage increase in life-span, %ILS = 100 × (mean survival days of the treated group - mean survival days of the vehicle control group/mean survival days of the vehicle control group). The vehicle control group had a mean survival period of 12.9 days. After 10 mg of rugosin D, the %ILS value was 171.5 and one animal showed no tumours on day 60. The authors suggested that the antitumour activity was likely to be through potentiation of the immunity of host animals rather than direct activity on the tumour cells [Miyamoto 1987].

Clinical studies
After local application of an ointment containing a decoction of meadowsweet flowers to 48 patients with cervical dysplasia, a positive response was recorded in 32 patients (67%), including 25 cases (52%) of complete regression of dysplasia. No recurrence was observed within 12 months in 10 completely cured patients [Peresun`ko 1993].

Pharmacokinetic properties
Ellagitannins are converted into urolithins by decarboxylation of the lactone rings by the gut microflora [Piwowarski 2014].

Preclinical safety data
For an ethanolic spissum extract of meadowsweet as a 5% aqueous solution, the i.p. LD_{50} in mice and i.v. LD_{50} in rabbits were determined as 1770 mg/kg and 75.7 mg/kg respectively. For a decoction (1:20), the i.p. LD_{50} in male and female mice, and the i.v. LD_{50} in rabbits, were found to be 535 mg/kg, 1050 mg/kg and 141.5 mg/kg respectively [Barnaulov 1977].

Pharmacological studies of meadowsweet flowers and their extracts in rats and rabbits did not show any influence on liver function [Barnaulov 1984].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me, on behalf of my colleagues in ESCOP, to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale

FOENICULI AETHEROLEUM 2019

Bitter-Fennel Fruit Oil

DEFINITION

Bitter-fennel fruit oil is obtained by steam distillation from the ripe fruits of *Foeniculum vulgare* Miller subsp. *vulgare* var. *vulgare* [Bitter-fennel fruit oil].

The material complies with the monograph of the European Pharmacopoeia [Bitter-fennel fruit oil].

CONSTITUENTS

Bitter-fennel fruit oil contains predominantly anethole (55.0-75.0%) and fenchone (12.0-25.0%) with not more than 6% of estragole. It also contains α-pinene, limonene, camphene, *p*-cymene, β-pinene, β-myrcene, α-phellandrene, sabinene, γ-terpinene and terpinolene [Brand 2007, Tóth 1967; Trenkle 1972; Tschiggerl 2010].

Chemotypes with essential oil containing a high amount of estragole (79-94%) and very little *trans*-anethole (<1%) have been identified [Miralda 1999; Miguel 2010]. These chemotypes do not comply with the monograph of the European Pharmacopoeia.

Sweet fennel oil from the fruit or herb of *Foeniculum vulgare* Miller subsp. *vulgare* var. *dulce* (Miller) Thellung also exists. It contains more than 75% anethole with not more than 6% of estragole and not more than 8% of fenchone [Tóth 1967;Trenkle 1972]. Sweet fennel oil does not comply with the monograph of the European Pharmacopoeia.

CLINICAL PARTICULARS

Therapeutic indications

Dyspeptic complaints such as mild, spasmodic gastro-intestinal ailments, bloating and flatulence [Brand 2007].

Catarrh of the upper respiratory tract [Brand 2007; Brayfield 2014].

In these indications, efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adult daily dosage: 0.1-0.6 ml, or equivalent preparations [Brand 2007]. Fennel honey with 0.5 g fennel oil/kg:10-20 g, or equivalent preparations [Brand 2007].

Children: Fennel syrup or fennel honey: *1-4years of age*, 3-6g; *4-10years of age,* 6-10g; *10-16 years of age*, adult dose [Dorsch 2002].

See note on safety concerns regarding estragole under preclinical safety data.

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist, consult your doctor.

Contra-indications
Persons with known sensitivity to anethole should avoid the use of fennel oil [Andersen 1978, Franks 1998].

Special warnings and special precautions for use
Persons with known sensitivity to anethole should avoid the use of fennel oil [Andersen 1978, Franks 1998].

E/S/C/O/P MONOGRAPHS

Interaction with other medicaments and other forms of interaction
None reported for humans.

Pregnancy and lactation
Preparations containing the essential oil or alcoholic extracts should not be used during pregnancy and lactation. Mild oestrogenic activity and antifertility effects of anethole (the major constituent of the essential oil) have been demonstrated in rats [Tisserand 1995, Dhar 1995].

Effects on ability to drive and use machines
None known.

Undesirable effects
Rare cases of contact dermatitis caused by anethole-containing preparations [Andersen 1978, Franks 1998].

Overdose
No toxic effects reported [Keller 1992].

PHARMACOLOGICAL PROPERTIES

As the type of fennel oil is rarely specified, it is referred to here as fennel oil.

Pharmacodynamic properties

In vitro experiments

Antimicrobial effects
Fennel oil inhibited the growth of *Escherichia coli* (MIC: 0.5% V/V), *Staphylococcus aureus* (MIC: 0.25%), *Salmonella typhimurium* (MIC: 1.0%) and *Candida albicans* (MIC: 0.5%) using the agar dilution method [Hammer 1999]. Significant antibacterial activity of the oil (10 µl of undiluted oil added to wells in agar plates) has been demonstrated against *Brevibacterium linens*, *Clostridium perfringens*, *Leuconostoc cremoris* and *Staphylococcus aureus* [Ruberto 2000]. Earlier studies also demonstrated antibacterial activity of the oil [Ramadan 1972, Afzal 1981].

Essential oil of bitter fennel fruit inhibited the food-born micro-organisms *Escherichia coli*, *Salmonella typhimurium*, *Listeria monocytogenes*, *Staphylococcus aureus* and *Salmonella enteridis* using the disc diffusion method with tetracycline and rifampicin as positive controls [Soylu 2009].

Fennel oil inhibited *Escherichia coli* (MIC:259.3µg/mL) and *Bacillus subtilis* (MIC:62.6 µg/mL). The MIC values for the positive control amoxicillin were 80.3µg/mL (*E. coli*) and 20.0 µg/mL (B. subtilis). The oil also showed antifungal activity against *Aspergillus niger* (MIC: 80.6 µg/mL), *Fusarium solani* (MIC: 91.1 µg/mL) and *Rhizopus solani* (MIC: 110.3µg/mL). For the positive control flumequine MICs were 30.3, 40.4 and 43.9 µg/mL respectively [Anwar 2009].

Using the disc diffusion method, fennel oil at 100 µg/disc showed antimicrobial activity against Gram-positive and Gram-negative bacteria and against *Candida albicans*, comparable to the activity of ofloxacin 6 µg/disc and miconazole nitrate 50 µg/disc. The MIC values tested in the agar dilution assay were 0.4-2.5% [Gulfraz 2008].

Antioxidant activity
Antioxidant activity of fennel oil against lipid peroxidation was demonstrated in the thiobarbituric acid reactive species assay and in a micellar model system [Ruberto 2000].

Free radical scavenging activities of fennel oil were demonstrated in the DPPH assay with an IC_{50} value of 32.32 µg/mL. The value for the positive control butylated hydroxytoluene (BHT) was 19.00 µg/mL.The oil also inhibited linoleic acid oxidation by 45.05%, while the value for BHT was 92.07% [Anwar 2009].

Anticoagulant activity
The anticoagulant properties of various compounds isolated from fennel were evaluated using a platelet aggregometer with acetylsalicylic acid as a positive control. Aggregation of rabbit platelets was induced by collagen. IC_{50} values for fenchone, estragole and acetylsalicylic acid were determined to be 3.9, 4.7 and 34.9 µM respectively [Lee 2006].

Fennel oil and anethole inhibited platelet aggregation in guinea pig plasma induced by arachidonic acid, collagen, adenosine diphosphate and U46619 (IC_{50} values 4-147 µg/mL) [Tognolini 2007].

Effects on musculature
The essential oil had a spasmogenic effect on smooth muscle of isolated guinea-pig ileum at a concentration of $8 + 10^{-5}$ g/mL. On a preparation of isolated rat phrenic nerve diaphragm it caused contracture and inhibition of the twitch response to nerve stimulation at a concentration of 2×10^{-4} g/mL [Lis-Balchin 1997].

Fennel oil significantly and dose-dependently reduced the intensity of oxytocin-induced contractions ($p<0.01$ at 50 µg/mL) and PGE_2-induced contractions ($p<0.01$ at 10 and 20 µg/mL) of the isolated rat uterus. The oil also reduced the frequency of contractions induced by PGE_2 (but not by oxytocin) [Ostad 2001].

Local anaesthetic activityof anethole
Trans-anethole concentration-dependently reduced electrically-evoked contractions of rat phrenic nerve-hemidiaphragm, by 10.3% at 10^{-3} µg/mL, by 43.9% at 10^{-2} µg/mL, by 79.7% at 10^{-1} µg/mL and by 100% at 1 µg/mL [Ghelardini 2001].

Tumour-inhibiting activity of anethole
Anethole at a concentration below 1 mM has been shown to be a potent inhibitor of TNF-induced cellular responses, such as activation of NF-κB and other transcription factors, and also to block TNF-induced activation of the apoptotic pathway. This might explain the role of anethole in suppression of inflammation and carcinogenesis [Chainy 2000].

Cytotoxic effect
Fennel oil showed cytotoxic effects in six different cancer cell lines with IC_{50} values of 0.51-3.78 µg/mL [EL-Bastawesy 2008].

In vivo experiments

Secretolytic and expectorant effects
Anethole and fenchone vapour were given by inhalation to urethanized rabbits at doses of 1 to 243 mg/kg b.w. added to the steam vaporizer (the amount actually absorbed by the animals was estimated as not more than 1% of that added to the vaporizer). Inhalation of anethole did not affect the volume but produced a dose-dependent (1-9 mg/kg) decrease in the specific gravity of respiratory tract fluid. Inhalation of fenchone produced a dose-dependent (1-9 mg/kg) augmentation of the volume output of respiratory tract fluid and a dose-dependent (1-27 mg/kg) decline in its specific gravity [Boyd 1971].

Oestrogenic effects
Trans-anethole administered orally to immature female rats at 80 mg/kg b.w. for 3 days significantly increased uterine weight, to 2 g/kg compared to 0.5 g/kg in controls and 3 g/kg

in animals given oestradiol valerate subcutaneously at 0.1 µg/rat/day ($p<0.001$). The results confirmed that *trans*-anethole has oestrogenic activity; other experiments showed that it has no anti-oestrogenic, progestational, anti-progestational, androgenic or anti-androgenic activity [Dhar 1995].

Osteoporosis-prophylactic activity
The prophylactic effect of fennel oil was evaluated in an experi-mental osteoporosis model in 6 groups of rats (n=6 each). Group 1 were sham-operated (control) rats receiving saline, groups 2-6 were ovariectomized rats receiving fennel essential oil (500, 750 or 1000 mg/kg b.w.), estradiol valerate (5 mg/kg b.w.) or saline, i.p. daily for 30 days. The fennel oil dose dependently and significantly (at the two higher doses; $p \leq 0.05$) prevented bone density loss and increased uterine weight ($p \leq 0.05$) [Jaffary 2006].

Anti-tumour activity of anethole
In Swiss albino mice with Ehrlich ascites tumour (EAT) in the paw, anethole administered orally at 500 or 1000 mg/kg on alternate days for 60 days significantly and dose-dependently reduced tumour weight ($p<0.05$ at 500 mg/kg, $p<0.01$ at 1000 mg/kg), tumour volume ($p<0.01$ at 500 mg/kg, $p<0.001$ at 1000 mg/kg) and body weight ($p<0.05$ to 0.01) compared to EAT-bearing controls. Mean survival time increased from 54.6 days to 62.2 days (500 mg/kg) and 71.2 days (1000 mg/kg). Histopathological changes were comparable to those after treatment with cyclophosphamide (a standard cytotoxic drug). These and other results demonstrated the anticarcinogenic, cytotoxic and non-clastogenic nature of anethole [Al-Harbi 1995].

Administration of fennel oil to Ehrlich ascites carcinoma bearing mice, at 100 mg/kg b.w. for three days (on days one, five and nine), demonstrated a significant ($p<0.01$) increase of serum iron. Fennel essential oil combined with radiation showed significant improvements ($p<0.01$) in iron, TIBC and transferring levels in tumour and liver tissues [El-Bastawesy 2008].

Anti-genotoxic activity of anethole
In the mouse bone marrow micronucleus test, oral pre-treatment of mice with *trans*-anethole at 40-400 mg/kg b.w. 2 and 20 hours before i.p. injection of genotoxins led to moderate, dose-dependent protective effects against known genotoxins such as cyclophosphamide, procarbazine, N-methyl-N'-nitrosoguanidine, urethane and ethyl methane sulfonate ($p<0.05$ to $p<0.01$ at various dose levels). No significant increase in genotoxicity was observed when *trans*-anethole (40-400 mg/kg b.w.) was administered alone in this model [Abraham 2001].

Enzyme modulating effect of anethole
Experiments in which rats were injected i.p. with a mixture of *trans*-anethole (100 mg/kg b.w.) and [^{14}C] parathion (1.5 mg/kg) showed no significant effect of *trans*-anethole on metabolism and excretion of the insecticide. However, when rats were fed a diet containing 1% of *trans*-anethole for 7 days and subsequently cell fractions from the livers of these rats were incubated for 2 hours compared to the control group with [^{14}C]parathion, significantly less unchanged parathion (1.6%) was recovered compared to controls (12.5%). The data were interpreted as suggesting that feeding *trans*-anethole to rats for 7 days induced the synthesis of parathion-degrading liver enzymes [Marcus 1982].

Analgesic effect of fenchone
In the mouse tail-flick test, fenchone at dosages of 0.05-0.2 mL/kg b.w. showed a significant anti-nociceptive effect ($p \leq 0.05$) [Him 2008].

Antithrombotic effect
Daily oral administration of fennel oil and anethole to mice at 30 mg/kg b.w. for 15 days showed a significant activity ($p<0.05$) against thromboembolism induced by collagen and epinephrine as compared to control [Tognolini 2007].

Antihepatotoxic activity
In rats, i.p. administration of fennel oil at 0.3 mL/kg b.w. three times a week for seven weeks showed a hepatoprotective activity against carbon tetrachloride induced liver fibrosis. The effect was expressed as decreased levels of serum ASAT, ALAT, ALP and bilirubin. The results were confirmed by histological findings. Controls were untreated and carbon tetrachloride treated rats [Özbek 2004].

Pharmacological studies in humans
No published data available.

Clinical studies
In a randomized, placebo-controlled study involving 121 infants (2-12 weeks of age) with colic diagnosed according to Wessel 1954, the verum group (29 males, 33 females) received an oral aqueous emulsion of 0.1% fennel oil and 0.4% polysorbate 80 (minimum 5 mL, maximum 20 mL) up to 4 times a day before meals and at the onset of colic periods for 7 days. In addition, the parents were instructed to limit the consumption to 12 mL/kg b.w. per day. The placebo group (26 males, 33 females) received 0.4% polysorbate in water. Diaries of crying periods were entered for the 7 days before the trial and the 7 days of the trial. There was a significant ($p<0.01$) improvement found in the fennel treatment group. Colic was eliminated in 65% of the infants in the fennel oil emulsion group and in 23.7% of the infants in the control group, indicating a marked placebo effect [Alexandrovich 2003].

In a placebo controlled, double blind study, 50 patients (15-24 years old) with moderate to severe dysmenorrhea were given a capsule four times a day for three days from the start of their menstrual period for two consecutive cycles, containing either 30 mg of fennel oil or placebo (wheat flour). Pain intensity as assessed by a visual analogue scale was significantly ($p<0.01$) reduced in the verum group compared to the placebo group [Omidvar 2012].

In an open study, 80 female students (aged 18-23 years) with primary dysmenorrhea were randomly divided into two groups (n=40 each). For three consecutive cycles, the treatment group received a capsule containing 30 mg fennel oil every 4 hours, from about 3 days before menstruation until the end of the fifth day (8 days in total). The control group did not receive any treatment or placebo. Pain and weakness were significantly reduced ($p<0.05$) after the treatment [Ghodsi 2014].

A randomised, placebo-controlled, double-blind, double-dummy, multi-centre trial investigated the efficacy of fennel oil compared to low-dose combined oral contraceptive (OC) and placebo at inducing menstrual bleeding in women (aged 15 to 45 years) using depot medroxyprogesterone acetate, who had no menstrual bleeding for the previous 45-140 days. The three groups (n=26 each) each received one pill and two capsules per day for 21 days. Group 1: 1 OC pill and 2 placebo capsules, group 2: 1 placebo pill and 2 fennel capsules (30 mg fennel oil/capsule), group 3: 1 placebo pill and 2 placebo capsules. Significantly ($p<0.001$) more women in the fennel group (73%) and the OC group (81%) experienced menstrual bleeding compared to the placebo group (19%) [Mohebbi-Kian 2014].

Pharmacokinetic properties

Pharmacokinetics in animals
No data available for fennel oil.

In mice and rats *trans*-anethole is reported to be metabolized by O-demethylation and by oxidative transformation of the C3-side chain. After low doses (0.05 and 5 mg/kg b.w.) *O*-demethylation occurs predominantly, whereas higher doses (up to 1500 mg/kg b.w.) give rise to higher yields of oxygenated metabolites [Sangster 1984].

Pharmacokinetics in humans
No data available for fennel oil.

After oral administration of radioactively-labelled *trans*-anethole (as the *methoxy*-^{14}C compound) to 5 healthy volunteers at dose levels of 1, 50 and 250 mg on separate occasions, it was rapidly absorbed. 54-69% of the dose (detected as 14C) was eliminated in the urine and 13-17% in exhaled carbon dioxide; none was detected in the faeces. The bulk of elimination occurred within 8 hours and, irrespective of the dose level, the principal metabolite (more than 90% of urinary ^{14}C) was 4-methoxyhippuric acid [49, 50]. An earlier study with 2 healthy subjects taking 1 mg of *trans*-anethole gave similar results [Sangster 1987].

Preclinical safety data

Acute toxicity
The oral LD_{50} of bitter fennel oil in rats was determined as 4.52 mL/kg [Opdyke 1976]. Values of 3.8 g/kg [Opdyke 1974] and 3.12 g/kg [Von Skramlik 1959] have also been reported for fennel oil in rats, in a more recent study the oral LD_{50} was estimated to be 1.326 g/kg [Ostad 2001].

The oral LD_{50} for fennel oil in mice was determined as 6.15 mL/kg [Özbek 2002].

Intraperitoneal LD_{50} values for *trans*-anethole have been determined as 0.65-1.41 g/kg in mice and 0.9-2.67 g/kg in rats [Lin 1991].

Reproductive toxicity
Trans-anethole exerted dose-dependent anti-implantation activity after oral administration to adult female rats on days 1-10 of pregnancy. Compared to control animals (all of which delivered normal offspring on completion of term), *trans*-anethole administered at 50, 70 and 80 mg/kg b.w. inhibited implantation by 33%, 66% and 100% respectively. Further experiments at the 80 mg/kg dose level showed that in rats given *trans*-anethole only on days 1-2 of pregnancy normal implantation and delivery occurred; in those given anethole only on days 3-5 implantation was completely inhibited; and in those given *trans*-anethole only on days 6-10 three out of five rats failed to deliver at term. No gross malformations of offspring were observed in any of the groups. The results demonstrated that *trans*-anethole has antifertility activity. From comparison with the days 1-2 group (lack of antizygotic activity), the lower level of delivery in the days 6-10 group was interpreted as a sign of early abortifacient activity [Dhar 1995].

Fennel essential oil at a concentration of 0.93 mg/mL produced a significant ($p<0.0001$) reduction in the number of differentiated foci in isolated limb bud mesenchymal cells. The findings suggest that fennel essential oil at the studied concentrations may have toxic effects on foetal cells. There was however no evidence of teratogenicity [Ostad 2004].

Mutagenicity and carcinogenicity
Fennel oil (2.5 mg/plate) and *trans*-anethole (2 mg/plate) were mutagenic in the Ames test using *Salmonella typhimurium* strains TA 98 and TA 100, and mutagenicity was potentiated by S13 activation [Marcus 1982]. In another study, *trans*-anethole was mutagenic to *Salmonella typhimurium* TA 100 in the Ames test with S9 activation, doses of 30-120 µg/plate showing a dose-dependent increase in revertants which did not exceed twice the number of the control [Sekizawa 1982]. Other investigations with metabolic activation have confirmed that *trans*-anethole is weakly mutagenic [Lin 1991].

Sweet fennel oil gave positive results in the *Bacillus subtilis* DNA-repair test [Sekizawa 1982], but fennel oil gave a negative result in the chromosomal aberration test using a Chinese hamster fibroblast cell line [Ishidate 1984].

Estragole, a minor constituent of fennel oil, has shown mutagenic potential in a number of Ames tests and proved carcinogenic in animal models [De Vincenzi 2000, Scientific committee on food 2001].

Note on the safety of estragole
As a result of new estragole carcinogenicity data, fennel (and theoretically also fennel oil) has in some cases been reported as posing risks for humans.

It is important to note that toxicological studies with rodents almost always use high doses, the results of these subsequently extrapolated to low doses. The metabolism of estragole is not the same in rodents and humans. 1′-Hydroxyestragole is considered the putative proximate toxic metabolite, which after conversion to 1′-sulfooxyestragole leads to DNA adduct formation. In mice, urinary excretion of 1′-hydroxyestragole glucuronide is dose dependent; from 1.3-5.4% at 0.05-50 mg/kg b.w. of estragole to 11.4-13.7% at 500-1000 mg/kg b.w. of estragole. In humans, 1′-hydroxyestragole glucuronide in urine stays constant at 0.2-0.4% over a wide dose range of 0.01-50 mg/kg b.w. of estragole [Gori 2012, Raffo 2011, Uusitalo 2016].

Attempts have been made to analyse or estimate the amount of estragole present in available fennel preparations [Raffo 2011, Uusitalo 2016]. Based on these data, daily consumption of three portions of herbal tea, could yield 0.2 mg of estragole, close to the average 0.166mg reported as the FAO/WHO estimate of daily consumption of estragole from spices and flavourings by the USA population.

Furthermore, all of the animal studies used estragole as a pure compound. In the case of fennel infusions, estragole is present together with other substances that can ameliorate its effects. There are indications that flavonoids present in the infusions, including quercetin, kaempferol and nevadensin, were able to inhibit the formation of 1′-sulfooxyestragole from 1,-hydroxyestragole, without influencing the capacity to detoxify the latter via glucuronidation or oxidation [Iten 2004; Alhusainy 2010; Alhusainy 2012].

Clinical safety data
In a study of 121 infants treated orally with either an emulsion of 0.1% fennel oil or placebo for 7 days, no side effects were reported [Alexandrovich 2003].

In a placebo controlled, double-blind study of 50 patients treated with either 30mg fennel oil 4 times a day for 3 days or placebo, no side effects were reported [Omidvar 2012].

In an open study 40 patients received the same treatment without side effects [Ghodsi 2014].

In a double-blind, double-dummy study, 3 groups of patients (n=26 each) were treated with various combinations of fennel oil, low-dose oral contraceptive (CO) and placebo. In the CO group 8 patients reported nausea while 3 patients receiving fennel reported heartburn [Mohebbi-Kian 2014].

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

Typeset in Optima by Roberta Hutchins

Plant illustrated on the cover: *Foeniculum vulgare*

FOREWORD

It is a great pleasure for me, on behalf of my colleagues in ESCOP, to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

FOENICULI FRUCTUS 2019

Fennel Fruit

DEFINITIONS

Bitter fennel (Foeniculi amari fructus) consists of the dry, whole cremocarps and mericarps of *Foeniculum vulgare* Miller subsp. *vulgare* var. *vulgare*. It contains not less than 40 mL/kg of essential oil, calculated with reference to the anhydrous drug. The oil contains not less than 60.0 per cent of anethole and not less than 15.0 per cent of fenchone [Fennel, bitter].

Sweet fennel (Foeniculi dulcis fructus) consists of the dry, whole cremocarps and mericarps of *Foeniculum vulgare* Miller subsp. *vulgare* var. *dulce* (Miller) Thellung. It contains not less than 20 mL/kg of essential oil, calculated with reference to the anhydrous drug. The oil contains not less than 80.0 per cent of anethole [Fennel, sweet].

The materials comply with the monographs of the European Pharmacopoeia [Fennel bitter, Fennel sweet].

CONSTITUENTS

The characteristic constituents of bitter fennel include 3-8.5% of essential oil. The main components of the bitter fennel oil are anethole (50-75%) and fenchone (12-33%). It also contains estragole (2-5%), α-pinene, limonene, camphene, *p*-cymene, β-pinene, β-myrcene, α-phellandrene, sabinene, γ-terpinene and terpinolene [Tóth 1967; Trenkle 1972; Brand 2007; Tschiggerl 2010].The essential oil of sweet fennel contains predominantly anethole (80->90%), estragole (3-10%) and fenchone (1-10%). Other components include α-pinene and limonene [Brand 2007] as well as β-pinene, β-myrcene and *p*-cymene [Toth 1967; Trenkle 1972].

Fennel fruit also contains water-soluble glycosides of essential oil components, hydroxyfenchone glycoside, hydroxyl-*p*-menthane glycoside, 1,8-cineole glycoside and other water-soluble glycosides [Kitajima 1998a; 1998b; 1998c; Ishikawa 1998a;1998b; 1998c; 1998d]. As well as small amounts of flavonoids (e.g. kaempferol and quercetin glycosides) and the trimethoxyflavone nevadensin [Brand 2007, Alhusaini 2010].

Chemotypes with essential oil containing a high amount of estragole (79-94%) and very little trans-anethole (<1%) are identified [Miralda 1999; Miguel 2010]. These chemotypes do not comply with the monograph of the European pharmacopoeia.

CLINICAL PARTICULARS

Therapeutic indications

Dyspeptic complaints such as mild, spasmodic gastro-intestinal ailments, bloating and flatulence [Madaus 1976; Brand 2007; Bradley 2006; Stahl-Biskup 2009].
Catarrh of the upper respiratory tract [Madaus 1976; Merkes 1980; Müller-Limmroth 1980; Brand 2007; Fintelman; Weiss 2009; Stahl-Biskup 2009; Brayfield 2014].

For symptomatic treatment of discomfort associated with menstrual periods [Moslemi 2012; Nejad 2006; Jahromi 2003].

In these indications, the efficacy is plausible on the basis of human experience and longstanding use.

Posology and method of administration

Dosage

Adult daily dose: 5-7 g of crushed fruits as an infusion or equivalent aqueous preparations, i.e. instant teas [Brand 2007; Stahl-Biskup 2009].
Compound fennel tincture: 5-7.5 g [Brand 2007].
Fennel syrup or honey: 10-20 g [Brand 2007].

E/S/C/O/P MONOGRAPHS

Children, average daily dose: 0-1 year of age, 1-2 g of crushed fruits as an infusion or equivalent preparation, i.e. instant teas; *1-4 years of age*, 1.5-3 g; *4-10 years of age*, 3-5 g; *10-16 years of age*, the adult dose [Dorsch 2002].

Fennel syrup or fennel honey: *1-4 years of age*, 3-6 g; *4-10 years of age* 6-10 g; *10-16 years of age*, adult dose [Dorsch 2002].

See note on safety concerns regarding estragole under preclinical safety data.

Method of administration
For oral administration.

Duration of use
Infusions or equivalent preparations: If symptoms persist for more than two weeks, consult your doctor, especially for paediatric use.

Contra-indications
Persons with known sensitivity to anethole should avoid the use of fennel [Andersen 1978, Franks 1998].

Special warnings and special precautions for use
Persons with known sensitivity to anethole should avoid the use of fennel [Andersen 1978, Franks 1998].

Interaction with other medicaments and other forms of interaction
None reported for humans.

Pregnancy and lactation
Fennel fruit may be used during pregnancy and lactation at the recommended dosage, as infusions only [Keller 1992].

Effects on ability to drive and use machines
None known.

Undesirable effects
A single case of allergic reaction to fennel has been reported [Schwartz 1997].

Rare cases of contact dermatitis caused by anethole-containing preparations [Andersen 1978; Franks 1998].

Overdose
No toxic effects reported [Keller 1992].

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antimicrobial effects
Acetone, *n*-butanol, ethanol and ether extracts inhibited the growth of a range of bacteria including *Escherichia coli* and *Staphylococcus aureus*, and also exhibited antifungal activity against *Candida albicans* and other organisms [Maruzzella 1959].

An ethanolic (95%) dry extract inhibited the growth of *Staphylococcus aureus* and *Bacillus subtilis* with an MIC value of 1 mg/mL for both organisms [Tanira 1996].

A methanolic dry extract inhibited the growth of 15 different strains of *Helicobacter pylori* with an MIC of 50 µg/mL using the agar dilution method [Mahady 2005].

A methanolic dry extract inhibited Gram-positive and Gram-negative bacteria and *Candida albicans* with MIC values of 1.3-3.7% [Gulfraz 2008].

A water extract and an acetone extract (drug:solvent 1:1) inhibited the growth of various bacteria with MIC values of 20-80 mg/ml and 5-15 mg/mL respectively. Controls were distilled water and acetone. Bactericidal activity for the extracts was demonstrated by viable cell count studies [Kaur 2009].

Antioxidant activity
Free radical scavenging activities of 100% methanolic, 80% methanolic, 100% ethanolic and 80% ethanolic dry extracts of sweet fennel were demonstrated in the DPPH assay with IC_{50} values of 26.75 µg/mL, 24.25 µg/mL, 26.10 µg/mL and 23.61 µg/mL respectively. The value for the positive control butylated hydroxytoluene (BHT) was 19.00 µg/mL.The same extracts inhibited linoleic acid oxidation by 48.80%, 55.31%, 50.76% and 70.35% respectively. The value for BHT was 92.07% [Anwar 2009].

Aqueous and ethanolic dry extracts showed concentration dependant antioxidant activity in various assays. The extracts inhibited lipid peroxidation by 91.6% and 98.6% respectively; the results were comparable with the values for the positive controls butylated hydroxyanisole (BHA) and BHT (94.3% and 97.8% respectively [Oktay 2003].

An aqueous dry extract inhibited the CYP-mediated oxidation of paracetamol to the hepatotoxic metabolite *N*-acetyl-*p*-benzoquinoneimine. The IC_{50} value for CYP2E1 inhibition was 23±4 µg/ml [Langhammer 2014].

Secretolytic and expectorant effects
An increase of about 12% in mucociliary transport velocity was observed in isolated ciliated epithelium from the frog oesophagus 90 seconds after application of 200 µl of an infusion from bitter fennel (4.6 g per 100 mL of water) [Müller-Limmroth 1980].

Anticoagulant activity
The anticoagulant properties of different compounds isolated from fennel were evaluated using a platelet aggregometer with acetylsalicylic acid as a positive control. Aggregation of rabbit platelets was induced by collagen. IC_{50} values for fenchone, estragole and acetylsalicylic acid were determined to be 3.9, 4.7 and 34.9 µM respectively [Lee 2006].

Effects on musculature
A 30%-ethanolic extract from bitter fennel produced a concentration-dependent decrease in acetylcholine- and histamine-induced contractility of isolated guinea pig ileum at concentrations of 2.5-10.0 mL/litre; however, taking into account the effect of ethanol, only the results with histamine were significant ($p<0.005$ at 10 mL/L) [Forster 1980]. In the same test system, the extract at 2.5 and 10.0 mL/L also concentration-dependently reduced carbachol-induced contractility [Forster 1983].

Local anaesthetic activity
Trans-anethole concentration-dependently reduced electrically-evoked contractions of rat phrenic nerve-hemidiaphragm by 10.3% at 10^{-3} µg/mL, by 43.9% at 10^{-2} µg/mL, by 79.7% at 10^{-1} µg/mL and by 100% at 1 µg/mL [Ghelardini 2001].

Tumour-inhibiting activity of anethole
Anethole at a concentration below 1 mM has been shown to be a potent inhibitor of TNF-induced cellular responses, such as activation of NF-κB and other transcription factors, and also to block TNF-induced activation of the apoptotic pathway. This

might explain the role of anethole in suppression of inflammation and carcinogenesis [Chainy 2000].

In vivo experiments

Secretolytic and expectorant effects
Anethole and fenchone vapour were given by inhalation to urethanized rabbits as doses of 1 to 243 mg/kg b.w. added to the steam vaporizer (the amount actually absorbed by the animals being considerably less, estimated as not more than 1% of that added to the vaporizer). Inhalation of anethole did not affect the volume but produced a dose-dependent (1-9 mg/kg) decrease in the specific gravity of respiratory tract fluid. Inhalation of fenchone produced a dose-dependent (1-9 mg/kg) augmentation of the volume output of respiratory tract fluid and a dose-dependent (1-27 mg/kg) decline in its specific gravity [Boyd 1971].

Effects on the digestive tract
Fennel administered orally at 24 mg/kg b.w. increased spontaneous movement of the stomach in unanaesthetized rabbits and reduced the inhibition of stomach movement induced by sodium pentobarbitone [Niiho 1977].

An aqueous extract (10% w/v), perfused through the stomach of anaesthetized rats at 0.15 mL/min. and collected over periods of 20 min., significantly increased gastric acid secretion ($p<0.02$) to more than 3-fold compared to the basal secretion determined from perfusion of saline solution [Vasudevan 2000].

Addition of 0.5% of fennel to the diet of rats for 6 weeks shortened food transit time by 12% ($p<0.05$) [Platel 2001].

Anti-inflammatory effects
Oral pre-treatment of rats with a dry 80%-ethanolic extract from sweet fennel at 100 mg/kg b.w. inhibited carrageenan-induced paw oedema by 36% ($p<0.01$) compared to 45% inhibition by indometacin at 5 mg/kg [Mascolo 1987].

Oral treatment with a methanolic (80%) dry extract (200mg/kg b.w.) significantly ($p \leq 0.05$) reduced carrageenan-induced rat paw oedema compared to control (10 mg/kg 0.5% sodium carboxymethyl cellulose).The same extract significantly ($p \leq 0.05$) reduced arachidonic acid-induced mouse ear oedema [Mascolo 1987].

In the formaldehyde-induced arthritis assay, a model for subacute inflammation, daily application (200 mg/kg/day for 7 days) significantly ($p \leq 0.05$) decreased the plasma activity of alanine aminotransferase compared to control. The results were comparable with indomethacin 10 mg/kg b.w. [Choi 2004].

Pre-treatment of rats with an unspecified ethanolic dry extract at 50, 100 and 200 mg/kg b.w. i.p. significantly ($p<0.05$) reduced carrageenan-induced paw oedema. The effect of 100 mg/kg of the extract was comparable to diclofenac at 10 mg/kg b.w., while 200 mg/kg b.w. was found to be more effective than the standard drug [Elisabeth 2014].

Oestrogenic effects
Oral administration of an acetone extract to adult female ovariectomized rats at 0.5-2.5 mg/kg b.w. caused dose-dependent oestrogenic effects: induction of the oestrus phase (after 10 days, in 40% of rats at 0.5 mg/kg, in 100% at 2.5 mg/kg), increase in mammary gland weight ($p<0.05$ at 0.5 mg/kg, $p<0.01$ at 2.5 mg/kg) and increase in weights of endometrium, cervix and vagina ($p<0.01$ to $p<0.001$ at 2.5 mg/kg). Oestrogenic effects were also evident in mature male rats after treatment with the extract at 1.5 or 2.5 mg/kg/day for 15 days: no significant change in body or organ weights but, particularly at the higher dose, significant changes in protein and acid and alkaline phosphatases in the testes, vas deferens, seminal vesicles and prostate were shown [Malini 1985].

Trans-anethole administered orally to immature female rats at 80 mg/kg b.w. for 3 days significantly increased uterine weight, to 2 g/kg compared to 0.5 g/kg in controls and 3 g/kg in animals given oestradiol valerate subcutaneously at 0.1 µg/rat/day ($p<0.001$). The results confirmed that *trans*-anethole has oestrogenic activity; other experiments showed that it has no anti-oestrogenic, progestational, anti-progestational, androgenic or anti-androgenic activity [Dhar 1995].

Antifertility effect
Oral administration of an aqueous dry extract to male rats in daily doses of 250 and 500 g/kg b.w. for 60 days, caused a significant decrease ($p<0.01$ and $p<0.001$) in the weight of reproductive organs (testes, epididymis, seminal vesicle, ventral prostate and vas deferens) compared to control (distilled water). The motility of spermatozoa and their density were diminished significantly ($p<0.01$). The study also showed a significant ($p<0.001$) reduction in the number of pregnancies, fertilizations and implantations [Agarwal 2006a].

Oral administration of a hydroethanolic (50%) extract to male rats at a daily dose of 100 mg extract corresponding to 2.5 g herbal drug/kg b.w. for 60 days, showed a significantly ($p<0.01$) reduced total protein content of the reproductive organs compared to control (water). Sperm motility was decreased significantly ($p<0.0001$) and fertility was reduced to 20% [Agarwal 2006b].

Hypotensive effect
A lyophilized aqueous extract administered orally at 190 mg/kg b.w. (equivalent to crude drug at 1000 mg/kg) for 5 days significantly lowered the systolic blood pressure of spontaneously hypertensive (SH) rats ($p<0.05$), but had no effect on blood pressure of normotensive rats. The extract also significantly increased the urine output of SH rats, by 80% at day 3 ($p<0.05$), and increased renal excretion of sodium and potassium ($p<0.05$), suggesting that fennel acted mainly as a diuretic and natriuretic in the SH rats [El Bardai 2001].

Anti-tumour activity
In Swiss albino mice with Ehrlich ascites tumour (EAT) in the paw, anethole administered orally at 500 or 1000 mg/kg on alternate days for 60 days significantly and dose-dependently reduced tumour weight ($p<0.05$ at 500 mg/kg, $p<0.01$ at 1000 mg/kg), tumour volume ($p<0.01$ at 500 mg/kg, $p<0.001$ at 1000 mg/kg) and b.w. ($p<0.05$ to 0.01) compared to EAT-bearing untreated controls. Mean survival time increased from 54.6 days to 62.2 days (500 mg/kg) and 71.2 days (1000 mg/kg). Histopathological changes were comparable to those after treatment with cyclophosphamide (a standard cytotoxic drug). These and other results demonstrated the anticarcinogenic, cytotoxic and non-clastogenic nature of anethole [Al-Harbi 1995].

Fennel fruit given to mice for 15 days at concentrations of 4% and 6% in test diets significantly ($p<0.01$) reduced dimethylbenzpyrene- and croton oil-induced skin papillogenesis and benzo[a]pyrene-induced fore stomach papillogenesis, compared to controls (normal diet). A significant enhancement ($p<0.01$) in the activities of the antioxidant enzymes were also demonstrated [Singh 2008].

Anti-genotoxic activity of anethole
In the mouse bone marrow micronucleus test, oral pre-treatment

of mice with *trans*-anethole at 40-400 mg/kg b.w. 2 and 20 hours before i.p. injection of genotoxins led to moderate, dose-dependent protective effects against known genotoxins such as cyclophosphamide, pro-carbazine, N-methyl-N'-nitrosoguanidine, urethane and ethyl methane sulfonate ($p<0.05$ to $p<0.01$ at various dose levels). No significant increase in genotoxicity was observed when trans-anethole (40-400 mg/kg b.w.) was administered alone [Abraham 2001].

Enzyme modulating effect
Experiments in which rats were injected i.p. with a mixture of *trans*-anethole (100 mg/kg b.w.) and [^{14}C] parathion (1.5 mg/kg) showed no significant effect of *trans*-anethole on metabolism and excretion of the insecticide. However, when rats were fed a diet containing 1% of trans-anethole for 7 days and subsequently cell fractions from the livers of these rats were incubated for 2 hours compared to the control group with [14C]parathion, significantly less unchanged parathion (1.6%) was recovered compared to controls (12.5%). The data were interpreted as suggesting that feeding *trans*-anethole to rats for 7 days induced the synthesis of parathion-degrading liver enzymes [Marcus 1982].

Antioxidant activity
Oral administration of a methanolic dry extract to rats at 200 mg/kg b.w., significantly ($p<0.05$) increased the plasma superoxide dismutase and catalase activities and the HDL-cholesterol level [Choi 2004].

Analgesic effect
In the mouse tail-flick test i.p.administered fenchone at dosages of 0.05-0.2 mL/kg b.w. showed a significant anti-nociceptive effect ($p\leq0.05$) [Him 2008].

An unspecified fennel ethanolic dry extract at 50, 100 and 200 mg/kg b.w. i.p. significantly ($p<0.01$) decreased acetic acid-induced writhing in mice. The results for 100 and 200 mg/kg were comparable with diclofenac sodium at 10mg/kg b.w. The same dosages of the extract significantly ($p<0.001$) reduced the number of formalin induced paw lickings. The results were comparable with those of diclofenac 10mg/kg b.w. and pentazocine 5mg/kg b.w. [Elisabeth 2014].

The analgesic activity of a methanolic (80%) dry extract was demonstrated using the hot-plate test in mice at an oral dosage of 200 mg/kg b.w. The extract significantly ($p\leq0.05$) reduced the hot-plate thermal stimulation [Choi 2004].

Oral administration to mice of an ethanolic (95%) dry extract at 500 mg/kg b.w. showed significant analgesic effect after 90 min. ($p<0.05$) and 150 min. ($p<0.01$) using the hot- plate method [Tanira 1996].

Antithrombotic effect
Daily oral administration of anethole to mice at 30 mg/kg b.w. for 15 days showed a significant activity ($p<0.05$) against thromboembolism induced by collagen and epinephrine as compared to control [Tognolini 2007].

Antipyretic activity
An ethanolic (95%) dry extract given orally at 500mg/kg b.w. to yeast-fevered mice caused a significant decrease ($p<0.01$) of the rectal temperature after 30 and 90 minutes [Tanira 1996].

Diuretic activity
An ethanolic (95%) dry extract administered orally to rats at 500 mg/kg b.w. showed a significant diuretic effect after 5 hours ($p<0.01$) and after 24 hours ($p<0.05$) as compared to control. The effect was comparable to that of urea at 960 mg/kg b.w. [Tanira 1996].

Pharmacological studies in humans
No published data available.

Clinical studies
In a randomised, double-blind, placebo controlled study, 38 women with diagnosed mild to moderate idiopathic facial hirsutism were treated twice a day for 12 weeks with a cream containing either a fennel ethanolic dry extract (1:12.5) at 1% or 2%, or a placebo (vehicle cream). Hair diameters were measured during the treatment period and necessary epilations served as an indirect measurement of the hair growth. The fennel extract containing creams reduced hair diameters by 7.8% and 18.3% respectively, and a decreased frequency of epilations was observed only in the fennel groups compared to placebo [Javidnia 2003].

In a randomized, double-blind, placebo-controlled study, 2 groups of 22 women aged 15-45 years old, with mild to moderate idiopathic hirsutism limited to the face, were treated with either a gel containing 3% of an 80% hydroalcoholic dry extract of fennel or a placebo gel. After 24 weeks of treatment the average thickness of the hairs was significantly ($p<0.001$) reduced in the fennel gel group compared to baseline [Akha 2014].

In an open study, 30 women aged 15-24 years old, with moderate to severe primary dysmenorrhoea, were evaluated for three menstrual cycles. In the first cycle no medication was given, in the second cycle the patients were treated orally with mefenamic acid at 250 mg every 6 hours, and in the third cycle with 2% sweet fennel water, 25 drops orally every 4 hours, during menstruation. The patients assessed the intensity of their dysmenorrhoea for each day of menstruation by a linear analogue technique with a scale of 1-10. Both treatments significantly ($p< 0.001$) relieved pain and other symptoms compared with control. Mefenamic acid had a more potent effect than fennel, but the difference was not significant [Jahromi 2003].

In a double-blind study involving young women with primary dysmenorrhoea, two groups of patients were randomized to receive 30 drops of an undefined fennel extract (n=55) or 250 mg of mefenamic acid (n=55), every 6 hours for the first 3 days of menstruation. After treatment, 80% of the fennel group and 73% of the mefenamic acid group had no pain. Fennel extract and mefenamic acid were equally effective in reducing limitations in activity and need for rest [Nejad 2006].

In a single blind, randomized, clinical study, female students suffering from mild or acute dysmenorrhoea were randomised into three groups of 25 each. The patients received capsules containing either a fennel hydroalcoholic extract (46 mg/capsule), vitamin E (100 I.U./capsule) or placebo, at one capsule every 6 hours for 3 days from the start of menstruation for 2 consecutive menstrual periods. If the pain persisted for more than 2 h after treatment they were allowed to use the analgesics they regularly used. The intensity of pain decreased significantly ($p<0.05$) in the fennel group [Moslemi 2012].

Pharmacokinetic properties

Pharmacokinetics in animals
No data available for fennel.

In mice and rats *trans*-anethole is metabolized by *O*-demethylation and by oxidative transformation of the C3-side chain. After low doses (0.05 and 5 mg/kg b.w.) *O*-demethylation occurs predominantly, whereas higher doses (up to 1500 mg/kg b.w.) give rise to higher yields of oxygenated metabolites [Sangster 1984a; 1984b].

Pharmacokinetics in humans
No data available for fennel.

After oral administration of radioactively-labelled *trans*-anethole (as the methoxy-^{14}C compound) to 5 healthy volunteers at dose levels of 1, 50 and 250 mg on separate occasions, it was rapidly absorbed. 54-69% of the dose (detected as ^{14}C) was eliminated in the urine and 13-17% in exhaled carbon dioxide; none was detected in the faeces. The bulk of elimination occurred within 8 hours and, irrespective of the dose level, the principal metabolite (more than 90% of urinary ^{14}C) was 4-methoxyhippuric acid [Caldwell 1988; Lin 1991]. An earlier study with 2 healthy subjects taking 1 mg of *trans*-anethole gave similar results [Sangster 1987].

Preclinical safety data

Acute toxicity
Oral administration of an ethanolic extract to mice at 0.5, 1 and 3 g/kg b.w. caused no mortality and no significant difference in body and vital organ weights or in external morphological, haematological or spermatogenic parameters in comparison with the control group over a period of 24 hours [Shah 1991].

Oral administration of an ethanolic (95%) dry extract at doses of 0.5, 1 and 3 g/kg b.w. did not cause any deaths in mice. The 3g/kg dose reduced locomotor activities [Tanira 1996].

The LD_{50} in mice given a dried ether extract i.p. was determined to be 5.52 mL/kg b.w. [Özbek 2003a].

LD_{50} values for i.p. *trans*-anethole have been determined as 0.65-1.41 g/kg in mice and 0.9-2.67 g/kg in rats [Lin 1991].

Subchronic toxicity
Oral administration of an ethanolic extract to mice at 100 mg/kg for 3 months caused no significant differences in mortality or in haematological and spermatogenic parameters compared to the control group [Shah 1991].

Reproductive toxicity
Trans-anethole exerted dose-dependent anti-implantation activity after oral administration to adult female rats on days 1-10 of pregnancy. Compared to control animals (all of which delivered normal offspring on completion of term), *trans*-anethole administered at 50, 70 and 80 mg/kg b.w. inhibited implantation by 33%, 66% and 100% respectively. Further experiments at the 80 mg/kg dose level showed that in rats given *trans*-anethole only on days 1-2 of pregnancy normal implantation and delivery occurred; in those given anethole only on days 3-5 implantation was completely inhibited; and in those given *trans*-anethole only on days 6-10 three out of five rats failed to deliver at term. No gross malformations of offspring were observed in any of the groups. The results demonstrated that *trans*-anethole has antifertility activity. From comparison with the days 1-2 group (lack of antizygotic activity), the lower level of delivery in the days 6-10 group was interpreted as a sign of early abortifacient activity [Dhar 1995].

Mutagenicity and carcinogenicity
Aqueous and methanolic extracts of fennel showed negative results in the Ames test using *Salmonella typhimurium* strains TA 98 and TA 100, with or without metabolic activation [Morimoto 1982; Yamamoto 1982]. These extracts also gave negative results in the *Bacillus subtilis* rec-assay [Morimoto 1982].

Trans-anethole (2 mg/plate) was mutagenic in the Ames test using *Salmonella typhimurium* strains TA 98 and TA 100, and mutagenicity was potentiated by S13 activation [Marcus 1982]. In another study, *trans*-anethole was mutagenic to *Salmonella typhimurium* TA 100 in the Ames test with S9 activation, doses of 30-120 µg/plate showing a dose-dependent increase in revertants which did not exceed twice the number of the control [Sekizawa1982]. Further investigations with metabolic activation have confirmed that trans-anethole is weakly mutagenic [Lin 1991].

Estragole, a constituent of fennel fruit, has shown mutagenic potential in a number of Ames tests and proved carcinogenic in animal models [De Vincenzi 2000; Scientific committee on food 2001;Iten 2004; Raffo 2011].

Note on the safety of estragole
As a result of new estragole carcinogenicity data, fennel (and theoretically also fennel oil) has in some cases been reported as posing risks for humans.

It is important to note that toxicological studies with rodents almost always use high doses, the results of these subsequently extrapolated to low doses. The metabolism of estragole is not the same in rodents and humans. 1′-Hydroxyestragole is considered the putative proximate toxic metabolite, which after conversion to 1′-sulfooxyestragole leads to DNA adduct formation. In mice, urinary excretion of 1′-hydroxyestragole glucuronide is dose dependent; from 1.3-5.4% at 0.05-50 mg/kg b.w. of estragole to 11.4-13.7% at 500-1000 mg/kg b.w. of estragole. In humans, 1′-hydroxyestragole glucuronide in urine stays constant at 0.2-0.4% over a wide dose range of 0.01-50 mg/kg b.w. of estragole [Gori 2012, Raffo 2011, Uusitalo 2016]. Attempts have been made to analyse or estimate the amount of estragole present in available fennel preparations [Raffo 2011, Uusitalo 2016]. Based on these data, daily consumption of three portions of herbal tea, could yield 0.2 mg of estragole, close to the average 0.166mg reported as the FAO/WHO estimate of daily consumption of estragole from spices and flavourings by the USA population.

Furthermore, all of the animal studies used estragole as a pure compound. In the case of fennel infusions, estragole is present together with other substances that can ameliorate its effects. There are indications that flavonoids present in the infusions, including quercetin, kaempferol and nevadensin, were able to inhibit the formation of 1′-sulfooxyestragole from 1,-hydroxyestragole, without influencing the capacity to detoxify the latter via glucuronidation or oxidation [Iten 2004; Alhusainy 2010; Alhusainy 2012].

Clinical safety data
In a randomized, double-blind, placebo controlled study, 68 infants with a diagnosis of infantile colic received either a preparation containing chamomile, vervain, licorice and fennel, or placebo. No adverse effects were observed [Weizman 1993].

In a study of 93 infants treated with an undefined extract of *Matricaria chamomilla*, *Foeniculum vulgare* var. *dulce* and *Melissa officinale*, no adverse effects were observed [Savino 2005].

In a randomized, double-blind, placebo controlled study of 44 women treated topically with a gel containing 3% of a hydroethanolic fennel extract, 3 patients reported dermal irritation and 7 patients reported itching [Akha 2014].

No adverse effects were observed in a study involving 38 women treated topically (on the face) with a cream containing fennel ethanolic dry extract twice a day for 12 weeks [Javidnia 2003].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

FRANGULAE CORTEX 2017

Frangula Bark

DEFINITION

Frangula bark consists of the dried, whole or fragmented bark of the stems and branches of *Rhamnus frangula* L. (*Frangula alnus* Miller). It contains not less than 7.0 per cent of glucofrangulins, expressed as glucofrangulin A ($C_{27}H_{30}O_{14}$; Mr 578.5) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Frangulae cortex].

CONSTITUENTS

The main active constituents of the dried bark are glucofrangulins A and B (emodin-6-O-α-L-rhamnosyl-8-O-β-D-glucoside and emodin-6-O-β-D-apiosyl-8-O-β-D-glucoside respectively), frangulins A, B and C (emodin-6-O-β-L-rhamnoside, emodin-6-O-β-D-apioside and emodin-6-O-β-D-xyloside), and emodin-8-O-β-D-glucoside, together with small amounts of other anthraquinone glycosides, dianthrones and aglycones [Wagner 1969; Labadie 1970; Hörhammer 1972; Wagner 1974; Lemli 1978; Hänsel 1994; Hänsel 1999].

CLINICAL PARTICULARS

Therapeutic indications
For short term treatment of occasional constipation [Preston 1986; Sonnenberg 1989].

Posology and method of administration

Dosage
The correct individual dose is the smallest required to produce a comfortable soft-formed motion.

Adults and children over 12 years: preparations equivalent to 20-30 mg of glucofrangulins daily, calculated as glucofrangulin A [Hänsel 1994].
Elderly: dose as for adults.

Not recommended for use in children under 12 years of age.
The pharmaceutical form must allow lower dosages.

Method of administration
For oral administration.

Duration of administration
Use for more than 1 – 2 weeks requires medical supervision.
If the symptoms persist during the use of the medicinal product, a doctor or a pharmacist should be consulted.

Contraindications
Not to be used in cases of: intestinal obstruction and stenosis, atony, inflammatory bowel diseases (e.g. Crohn's disease, ulcerative colitis), appendicitis; abdominal pain of unknown origin; severe dehydration states with water and electrolyte depletion.
Not to be used in pregnancy or in children under 12 years of age [Hänsel 1994; Sweetman 2002].

Special warnings and precautions for use
As for all laxatives, frangula bark should not be given when any undiagnosed acute or persistent abdominal symptoms are present.

If laxatives are needed every day the cause of the constipation should be investigated. Long term use of laxatives should be avoided. Use for more than 2 weeks requires medical supervision. Chronic use may cause pigmentation of the colon (pseudomelanosis coli) which is harmless and reversible after drug

discontinuation. Abuse with diarrhoea and consequent fluid and electrolyte losses may cause: dependence with possible need for increased dosages; disturbance of the water and electrolyte (mainly hypokalaemia) balance; an atonic colon with impaired function. Intake of anthranoid-containing laxatives for more than a short period of time may result in aggravation of constipation. Hypokalaemia can result in cardiac and neuromuscular dysfunction, especially if cardiac glycosides, diuretics or corticosteroids are taken. Chronic use may result in albuminuria and haematuria.

In chronic constipation stimulant laxatives are not an acceptable alternative to a changed diet [Preston 1986; Müller-Lissner 1988; Sonnenberg 1989; Bingham 1989; Coenen 1990; Klauser 1990a, Klauser 1990b; Bingham 1991; Klauser 1992; Hänsel 1994; Sweetman 2002].

Note: A detailed text with advice concerning changes in dietary habits, physical activities and training for normal bowel evacuation should be included on the package leaflet. An example is given in the booklet "Médicaments à base de plantes" published by the French health authority (Paris: Agence du Médicament).

Interaction with other medicinal products and other forms of interaction
Hypokalaemia (resulting from long term laxative abuse) potentiates the action of cardiac glycosides and interacts with antiarrhythmic drugs or with drugs which induce reversion to sinus rhythm (e.g. quinidine). Concomitant use with other drugs inducing hypokalaemia (e.g. thiazide diuretics, adrenocorticosteroids and liquorice root) may aggravate electrolyte imbalance [Hänsel 1994].

Pregnancy and lactation

Pregnancy
Not recommended during pregnancy.

There are no reports of undesirable or damaging effects during pregnancy or on the foetus when used in accordance with the recommended dosage schedule. However, experimental data concerning a genotoxic risk from several anthranoids (e.g. emodin and physcion) and frangula bark extract are not counterbalanced by sufficient studies to eliminate a possible risk [Schmidt 1955; Brown 1976; Liberman 1980; Tikkanen 1983; Bruggeman 1984; Westendorf 1990; Westendorf 1993].

Lactation
Breastfeeding is not recommended as there are insufficient data on the excretion of metabolites in breast milk.

Excretion of active principles in breast milk has not been investigated. However, small amounts of active metabolites (e.g. rhein) from other anthranoids are known to be excreted in breast milk. A laxative effect in breast-fed babies has not been reported [Faber 1988; Sweetman 2002].

Effects on ability to drive and use machines
None known.

Undesirable effects
Abdominal spasms and pain, in particular in patients with irritable colon; yellow or red-brown (pH dependent) discolouration of urine by metabolites, which is not clinically significant [Cooke 1977; Tedesco 1985; Ewe 1986; Hänsel 1994; Sweetman 2002].

Overdose
The major symptoms are griping and severe diarrhoea with consequent losses of fluid and electrolyte, which should be replaced.

Treatment should be supportive with generous amounts of fluid. Electrolytes, particularly potassium, should be monitored; this is especially important in the elderly and the young [Hänsel 1994].

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

1,8-dihydroxyanthracene derivatives possess a laxative effect. For the greater part the glycosides (frangulins and glucofrangulins) are not absorbed in the upper gut; they are converted by the bacteria of the large intestine into the active metabolite (emodin-anthrone). There are two different mechanisms of action:

(i) an influence on the motility of the large intestine (stimulation of peristaltic contractions and inhibition of local contractions) resulting in accelerated colonic transit, thus reducing fluid absorption,

(ii) an influence on secretion processes (stimulation of mucus and active chloride secretion) resulting in enhanced fluid secretion [Casparis 1925; Schultz 1952;Ferguson 1956; Cresseri 1966; Fairbairn 1970; van Os 1976; Fairbairn 1976; Lemmens 1976; Longo 1980; de Witte 1993].

Defecation takes place after a delay of 8-12 hours due to the time taken for transport to the colon and metabolization into the active compound.

In vitro experiments
Emodin inhibited the aggregation of rabbit platelets induced by arachidonic acid and collagen, without affecting that induced by ADP or PAF. Frangulin B selectively and dose-dependently inhibited collagen-induced aggregation and ATP release in rabbit platelets, without affecting those induced by arachidonic acid, ADP, PAF and thrombin. Frangulin B also inhibited the platelet aggregation induced by trimucytin, a collagen receptor agonist [Teng 1993].

Frangulin B showed potent inhibitory activity against tumour necrosis factor-α (TNF-α) formation in lipopolysaccharide/γ-interferon-stimulated murine microglial cell line N9 (IC_{50}: 42.6 µM, $p<0.01$) [Wei 2001].

Anti-proliferative properties
Emodin displays antiproliferative properties which seem to be related to its role in the regulation of redox status, inhibition of kinases, through activation of microsomal enzymes, activation of repair mechanisms in various cellular systems generating ROS (reactive oxygen species) and increasing the susceptibility of tumour cells to standard cytotoxic therapeutic agents [Shieh 2004, Srinivas 2007].

Other effects
A methanolic extract (undefined) of frangula bark containing anthraquinones and flavonoids was active against various fungi *in vitro* [e.g. *Trichoderma viride, Doratomyces stemonitis, Aspergillus niger, Penicillium verrucosum, Alternaria alternate, Aueobasidium pullulans* and *Mucor mucedo*], and was in most cases superior to isolated emodin [Manjlovic 2005].

Clinical studies
In a randomized, controlled clinical trial, 45 post-colostomy surgery patients received either a standardized postsurgical laxative protocol (n = 19; intervention group) or laxative

treatments as preferred by the surgical team (n = 26; comparison group). The standardized protocol consisted of first line treatment with either a combination of sterculia and frangula bark or liquid paraffin, and second line treatment with an iso-osmotic polyethylene glycol. The effects of the treatments on constipation were compared, as measured by faecal loading on plain abdominal film, stomal therapy nurse activity, patient comfort and length of hospital stay. The presence of faecal loading (constipation) was lower (p=0.05) in the intervention group (1 episode) compared to the comparison group (7 episodes). Stomal therapy nurse activity, in terms of the number of empty bag changes, was significantly higher in the comparison group (p=0.03). No statistically significant difference was found regarding the other 2 parameters. The findings of the study support the benefits of this standardized laxative protocol for prevention of constipation for post-colostomy surgery patients [Stott 2012].

Pharmacokinetic properties

It is generally assumed (by analogy with sennosides from senna) that the glycosides (frangulins and glucofrangulins) are largely not split by human digestive enzymes in the upper gut and therefore not absorbed to a large extent. They are converted by the bacteria of the large intestine into the active metabolite (emodin-anthrone). Mainly anthraquinone aglycones are absorbed and transformed into their corresponding glucuronide and sulphate derivatives. After oral administration of frangula bark extract, rhein, emodin and traces of chrysophanol are found in human urine [Longo 1980; de Witte 1993].

Oral administration of emodin to rabbits at 10 mg/kg b.w. resulted in a very low serum concentration (approximately 2.5 µg/ml). Emodin was found to be highly bound (99.6%) to serum protein [Liang 1995].

Preclinical safety data

No studies are available on single dose toxicity, repeated dose toxicity, reproductive toxicity or on *in vivo* carcinogenicity of frangula bark or frangula bark preparations.

Embryonic / Developmental toxicity

Mouse embryos at the blastocyst stage administered *in vitro* with 25-75µM emodin exhibited significantly increased apoptosis and a corresponding decrease in total cell number. The implantation success rate of blastocysts pretreated with emodin was lower than that of control. Moreover, *in vitro* treatment was associated with increased resorption of post-implantation embryos and decreased fetal weight. In an *in vivo* mouse model, the application of emodin in drinking water led to apoptosis and decreased cell proliferation, and inhibited early embryonic development to the blastocyst stage [Chang 2012a].

In an *in vivo* mouse model, application of drinking water containing 20-40µM emodin led to decreased oocyte maturation and *in vitro f*ertilization. Pretreatment with a caspase-3-specific inhibitor prevented these effects, suggesting that the impairment of embryo development occurs via a caspase-dependent apoptotic process [Chang 2012b].

The effects of emodin on embryo/fetal growth, viability and morphological development were studied in rats and mice. Ingested dose was 0, 31, 57 and 80-144 mg emodin/kg/day in rats and 0, 94, 391 and 1005 mg emodin/kg/day in mice. The rat maternal lowest observed adverse effect level (LOAEL) was 1700 ppm; the no adverse effect level (NOAEL) was 850 ppm. The rat developmental toxicity NOAEL was ≤1700 ppm; LOAEL not established. In mice, maternal toxicity NOAEL was 2500 ppm (LOAEL: 6000 ppm). The developmental toxicity LOAEL was 6000 ppm and the NOAEL was 2500 ppm [Jahnke 2004].

Genotoxicity/Cancerogenicity

Various frangula bark extracts have been shown to be genotoxic in several *in vitro* bacterial mutation tests. Emodin, the main laxative principle of frangula bark, was mutagenic in the Ames test but gave inconsistent results in gene mutation assays (V79 HGPRT), positive results in the UDS test with primary rat hepatocytes but negative results in the SCE assay. Other anthraquinone constituents also gave positive results in limited experiments [Brown 1976; Liberman 1980; Tikkanen 1983; Bruggeman 1984; Westendorf 1990; Müller 1996].

In a 2-year study, male and female F344/N rats were exposed to 280, 830 or 2500 ppm of emodin in the diet, corresponding to an average daily dose of emodin of 110, 320 or 1000 mg/kg b.w. in male rats and 120, 370 or 1100 mg/kg b.w. in female rats. No evidence of carcinogenic activity of emodin was observed in male rats. A marginal increase in the incidence of Zymbal's gland carcinoma occurred in female rats treated with the high dosage but was interpreted as questionable.

In a further 2-year study, on B6C3F1 mice, males were exposed to 160, 312 or 625 ppm of emodin (corresponding to an average daily dose of 15, 35 or 70 mg/kg b.w.) and females to 312, 625 or 1250 ppm of emodin (corresponding to an average daily dose of 30, 60 or 120 mg/kg b.w.). There was no evidence of carcinogenic activity in female mice. A low incidence of renal tubule neoplasms in exposed males was not considered relevant [NTP Technical Report 1999].

Clinical safety data

Despite a lack of formal preclinical data on frangula bark, epidemiological studies suggest that there is no carcinogenic risk in humans from the use of anthranoid laxatives [Loew 1994; Loew 1997; van Gorkom 1999].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

FUMARIAE HERBA

2018

Fumitory

DEFINITION

Fumitory consists of the whole or fragmented, dried aerial parts of *Fumaria officinalis* L. harvested in full bloom. It contains not less than 0.4 per cent of total alkaloids, expressed as protopine ($C_{20}H_{19}NO_5$; M_r 353.4) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Fumitory].

CONSTITUENTS

The main characteristic constituents are isoquinoline alkaloids (0.3-1.3%) of the protopine, spirobenzylisoquinoline, protoberberine, benzophenanthridine and indenbenzazepine types, the principal ones being protopine and fumarophycine together with sinactine, sanguinarine, fumarofine and others. Over 20 alkaloids have been identified [Manske 1938; MacLean 1969; Hermansson 1973; Murav'eva 1975; Forgacs 1982, 1986; Mardirossian 1983; Sener 1985; Sousek 1999; Suau 2002; Sturm 2006; Paltinean 2016; Gorecki 2010; Blaschek 2016].

Other constituents include flavonol glycosides such as quercitrin, isoquercitrin, rutin, quercetin 3,7-diglucoside, quercetin 3-arabinoglucoside and their aglycones [Massa 1971; Torck 1971; Păltinean 2017], aliphatic acids (fumaric and malic acids), several hydroxycinnamoylmalic acids (a total of 1.3%), and hydroxycinnamic acids including caffeic, coumaric, sinapic and ferulic acids [Boegge 1995; Sousek 1999, Ivanov 2014].

CLINICAL PARTICULARS

Therapeutic indications
Digestive complaints (e.g. stomach ache, nausea, vomiting, feeling of fullness, flatulence) due to hepatobiliary disturbance [Fablet 1963; Colson 1967; Roux 1967; Salembier 1967; Warembourg 1967; Dornier 1968; Devin 1969; Heully 1969; Fiegel 1971; Roux 1977; Zacharewicz 1979; Bradley 1992; Gorecki 2010; Blaschek 2016].

Posology and method of administration

Dosage

Adult daily dose: 4-6 g of the drug as an aqueous dry extract [Fablet 1963; Colson 1967; Roux 1967, 1977; Salembier 1967; Warembourg 1967; Dornier 1968; Devin 1969; Heully 1969; Fiegel 1971; Zacharewicz 1979] or infusion [Bradley 1992; Gorecki 2010; Barnes 2007; Blaschek 2016]; other equivalent preparations, e.g. liquid extract (1:1, ethanol 25% V/V) and tincture (1:5, ethanol 45% V/V) [Bradley 1992; Barnes 2007].

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contra-indications
Biliary obstruction.

Special warnings and special precautions for use
In cases of gallstones, fumitory should not be used without medical advice.

Interaction with other medicaments and other forms of interaction
None reported.

E/S/C/O/P
MONOGRAPHS

Pregnancy and lactation
No data available.

In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None known.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Effects on smooth muscle
An alkaloid-rich dry extract (not further specified) had a biphasic effect on isolated muscle, increasing resting tone at low concentrations (10^{-5} to 5×10^{-5} g/mL), and reducing the amplitude of spontaneous contractions at concentrations above 5×10^{-4} g/mL in isolated rabbit jejunum and 10^{-3} g/mL in isolated rat duodenum. The extract had a concentration-dependent smooth muscle-relaxing effect on barium chloride-induced contractions of isolated rat duodenum (EC_{50}: 10^{-4} g/mL), with approximately 5% of the effect of papaverine. At 10^{-5} to 10^{-4} g/mL the extract induced muscle contraction in isolated rat uterus, the effect being less pronounced at higher concentrations. In isolated dog saphenous vein it antagonized noradrenaline-induced contractions (EC_{50}: 8.5×10^{-6} g/mL), as did papaverine and protopine (EC_{50}: 2.9×10^{-5} and 2.3×10^{-5} g/mL respectively). In contrast, the extract increased spontaneous venous contraction within a concentration range of 10^{-6} to 10^{-4} g/mL [Reynier 1977].

An aqueous dry extract (not further specified) exhibited cholecystokinetic activity on isolated bile duct and Oddi's sphincter from pigs, as shown by contraction of the bile duct and relaxation of its Oddi's sphincter from a concentration of 10^{-4} g/mL. The extract at 5×10^{-4} g/mL inhibited morphine-induced contraction of Oddi's sphincter. In contrast, pure protopine at 10^{-5} to 10^{-7} g/mL had a strong contractile effect on Oddi's sphincter [Kimura 1972].

Neuroprotective effects
An alkaloid–rich extract (ethyl acetate; not further specified) was tested for the inhibition of acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE). The extract exhibited inhibitory activities against both enzymes with IC_{50} values of 39.23 ± 1.96 µg/mL and 40.32 ± 1.08 µg/mL respectively. The isolated alkaloids parfumidine and sinactine did not show any inhibitory activity on these enzymes but inhibited propyl oligopeptidase activity with IC_{50} values of 99 ± 5 µM and 53 ± 2 µM respectively [Chlebek 2016].

In another study, an alkaloid-rich extract (ethanol; not further specified) exhibited AChE inhibition with an IC_{50} value of 0.26 ± 0.01 mg/mL as compared to galanthamin with an IC_{50} value of 0.31 ± 0.05 mg/mL [Vrancheva 2016].

Other effects
Ethanolic extracts (not further specified) showed radical-scavenging activities in various assays such as DPPH and ABTS, as well as antioxidant capacity in CUPRAC, FRAP, lipid peroxidation and ferric reduction [Ivanov 2014; Khamtache-Abderrahim 2016].

An aqueous extract (not further specified) was tested in an *Agrobacterium tumefaciens*–induced potato disk tumour assay. The activity was similar to the positive control camptothecin (both 100%), compared to water as the negative control [Pehlivan Karakas 2012].

Protopine and allocryptopine induced a concentration-dependent increase in CYP1A1 mRNA in HepG2 cells after 24 h treatment. Both alkaloids induced a concentration-dependent increase of CYP1A1 and CYP1A2 mRNA in human hepatocytes, whereas the activation of the aryl hydrocarbon receptor in the induction of CYP1A mRNA levels by either protopine or allocryptopine was mild or negligible. Neither protopine nor allocryptopine caused an increase in CYP1A protein and activity levels in both cell types [Vrba 2011].

In vivo experiments

Hepatobiliary effects
No significant variations in bile flow were observed after intravenous administration of an aqueous dry extract (not further specified) to rats at 25, 50 and 100 mg/kg in the bile fistula model [Boucard 1966a, 1966b]. When the extract (50 mg/kg) was administered intravenously 30 minutes before or at the same time as sodium dehydrocholate (25 mg/kg), increases in bile flow 1 hour later were 45% and 28% respectively, compared to 66% when the choleretic agent was given alone [Boucard 1966b]. Under similar conditions, the increase in bile flow of 77% after sodium dehydrocholate (25 mg/kg) was reduced by simultaneous administration of the fumitory dry extract, to 55% (25 mg/kg of sodium dehydrocholate + 25 mg/kg of extract), 43% (25 mg/kg of sodium dehydrocholate + 50 mg/kg of extract) and 35% (25 mg/kg of sodium dehydrocholate + 100 mg/kg of extract) [Boucard 1966a]. A reduction in bile secretion induced by oral administration of 10 mg/kg of sodium azide was almost completely antagonized by simultaneous oral administration of the extract at 100 mg/kg [Boucard 1966b].

The same extract was administered intravenously to bile duct-cannulated dogs at 20 or 50 mg/kg. In dogs with low biliary output (0.09-0.20 mL/hour/kg) increases in bile flow of 29-218% were observed, while those with a high biliary output (0.63-1.38 mL/hour/kg) were characterized by reductions of 27-41%. Similar effects were observed with the extract in the presence of the choleretic agent sodium dehydrocholate, administered intravenously [Giroux 1966].

The choleretic activity of an aqueous dry extract (not further specified) intravenously administered at 40 mg/kg was confirmed in both normal rats and sodium azide-induced hypocholeretic rats in the bile fistula model. On the other hand, increased bile secretion induced by sodium hydrocholate was not reduced by intravenous administration of the extract at 40 mg/kg [Kimura 1972].

Intraduodenal administration of an alkaloid-rich dry extract (not further specified) to bile duct-cannulated rats at 200 mg/kg produced, not only an increase of 23% in bile flow, but also increases in biliary-excreted bilirubin and cholesterol of 33% and 20% respectively, in comparison to control. Under the same conditions protopine at 6 mg/kg produced comparable effects, while sodium dehydrocholate at 25 mg/kg had an effect only on the excreted volume [Reynier 1977].

The effect of an aqueous dry extract (not further specified) on

experimental cholelithiasis, induced by a diet supplemented with cholesterol-cholic acid, was evaluated in mice at two dosages, 0.2% and 0.4%, as an addition to their lithogenic diet. After 6 weeks of treatment the mean numbers of gallstones per mouse were significantly reduced ($p<0.05$), from 1.61 in the control group to 1.00 in the 0.2% group and 0.64 in the 0.4% group [Lagrange 1973].

Hepatoprotective effects
An aqueous dry extract (not further specified) was administered intravenously at 50 and 100 mg/kg b.w. to normal rats and to rats intoxicated with a single i.p. dose of carbon tetrachloride (CCl_4). Compared to controls 48 hours after administration of CCl_4, alkaline phosphatase activity was unchanged in excreted bile and serum, while in the liver it was significantly higher ($p<0.01$) in the group of CCl_4-intoxicated rats that received 50 mg/kg of extract and in each of the groups treated with 100 mg/kg of extract, indicating stimulation of hepatocytes [Guesnier 1974].

Cardiac effects of fumitory alkaloids
An extract comprising the total alkaloids (TAF, extracted with sulphuric acid and purified by ion exchange), administered intravenously to mice at 1-1.5 mg/kg, slowed the heart rate by 14-22% for 90 minutes. Cardiac fibrillation in mice induced by a normally lethal intravenous dose of calcium chloride was inhibited by TAF at 5 mg/kg i.v., enabling 50% of the animals to survive and delaying deaths of the other animals longer than in the control group ($p<0.001$); protopine at the same dose level did not influence survival, but 15% of animals survived after cryptopine at 10 mg/kg. TAF administered intravenously to rabbits prior to an arrhythmogenic dose of adrenaline prevented arrhythmia in 50% of the animals at 0.5 mg/kg and 90% at 1 mg/kg. Under the same conditions protopine was ineffective at 0.5 mg/kg but prevented arrhythmia in 40% of animals at 1 mg/kg, while cryptopine was ineffective at both dose levels [Gorbunov 1977].

A study in dogs demonstrated that TAF at 1-2 mg/kg i.v. prevented or substantially reduced ischaemic shifts caused by experimental occlusion of the coronary artery, while 5.5 mg/kg prevented arrhythmia induced by ligation of the intraventricular branch of the left coronary artery [Gorbunov 1980].

Diuretic activities
An ethanolic extract (not further specified) produced a significant ($p<0.05$) increase in urine volume of rats, 24 h after oral administration of a single dose of 250 mg/kg b.w. The extract also significantly ($p<0.05$) increased the urinary excretion of sodium and potassium [Paltinean 2017].

Neuropharmacological activities
An ethanolic extract (not further specified) administered i.p. to mice at doses of 200 and 500 mg/kg b.w. significantly ($p<0.01$) decreased the number of movements in the actophotometer assay, and also significantly ($p<0.01$) increased the time spent in the open arm and the number of entrances into the open arms in the elevated plus-maze test [Sharma 2014].

Pharmacological studies in humans

Amphocholeretic effect
In a study carried out 7-10 days after choledochostomy (establishment of external drainage from the bile duct) in 25 patients, bile flow was measured before and after a single oral dose of 1500 mg of an aqueous dry extract (not further specified). The extract had an amphocholeretic effect, promoting bile secretion if it was below the normal threshold and inhibiting bile secretion if it was excessive [Salembier 1967]. In a subsequent study of this type, daily oral administration of 4 × 250 mg of the same extract to 20 post-choledochostomy patients for an average of 12 days produced similar effects on bile secretion, increasing weak bile flow and reducing elevated bile flow; antispasmodic and biliary analgesic effects were also observed [Devin 1969].

In an open study, the effect on choleresis of a single dose of an aqueous dry extract (not further specified) was investigated in 20 healthy volunteers. They received either 500 mg of the extract in physiological serum (12 subjects) or placebo (8 subjects) through an intraduodenal probe. Monitoring of bile secretion for 30 minutes confirmed that the extract facilitated normalization of bile flow by increasing or decreasing the flow in relation to the baseline secretion [Heully 1969].

Clinical studies
In a randomized, double-blind, cross-over study 30 patients with various biliary disorders including dyskinesia, cholecystitis and post-cholecystectomy syndrome, which had previously been treated for 2 years without success, were treated with 6 × 250 mg of an aqueous dry extract (not further specified) or placebo daily for 14 days and consecutively vice versa in a second 14-day phase. The group taking the extract during the first phase experienced a significant reduction ($p<0.01$) in the intensity of symptoms (right upper abdominal pains, postprandial pains, flatulence, nausea, vomiting, stomach rumblings, impaired sleep and headaches) and this lasted throughout the subsequent placebo phase. In the other group the intensity of symptoms increased during the second week of placebo treatment and then declined significantly ($p<0.01$) during treatment with the extract in the second phase [Zacharewicz 1979].

In an open study 45 patients, previously treated for 2 years without success for dyskinesia of the biliary tract, post-cholecystectomy syndrome, chronic cholecystitis or cholangitis, received 4 × 250 mg of an aqueous dry extract (not further specified) daily for 16 days and were given a follow-up examination 14 days later. The overall improvement in symptoms (right upper abdominal pains, postprandial pains, flatulence, nausea, vomiting, stomach rumblings, impaired sleep and headaches) was very good in 32 (71%) and moderate in 7 patients, while no effect was apparent in the remaining 6 [Zacharewicz 1979].

Daily treatment of 105 patients with biliary disorders of various origin (dyskinesia, hepatomegaly, gallstone complaints and post-cholecystectomy symptoms) with 6 × 250 mg of an aqueous dry extract (not further specified) for 2 weeks to 6 months led to substantial improvements in, or complete absence of, symptoms (right upper abdominal pains, nausea, retching, occasional vomiting and poor tolerance of food) in more than 80% of patients [Fiegel 1971].

The efficacy of an aqueous dry extract (not further specified) was evaluated in five observational studies involving a total of 286 patients, treated in most cases with 750-1500 mg/day for 1-3 months. The patients could be classified into six groups: biliary dyskinesia (n=90), biliary lithiasis (n=23), migraine (frequently associated with concomitant nausea or vomiting; n=106), hepatobiliary insufficiency (n=29), post-cholecystectomy symptoms (n=29) and jaundice following viral hepatitis (n=9). Global efficacy assessed by the physicians was excellent or good in 75%, 100%, 83%, 75%, 72% and 66% of patients in the respective groups [Fablet 1963; Colson 1967; Roux 1967; Warembourg 1967; Dornier 1968].

Thirty-one patients suffering from diarrhoea or chronic constipation of biliary origin were given 1000 or 1500 mg of an aqueous dry extract (not further specified) respectively.

Improvement was excellent or good in 71% of cases after treatment periods of at least 15 days [Roux 1977].

Pharmacokinetic properties
No data available.

Preclinical safety data

Single dose toxicity
The acute intraperitoneal LD_{50} of an aqueous dry extract (not further specified) was 1.91 g/kg b.w. in mice and 1.88 g/kg in rats [Cahen 1964].

Repeated dose toxicity in rats
No delayed growth, changes in vital organs or haematological abnormalities were evident in rats following 3 months of oral treatment with an aqueous dry extract (not further specified) at 2.4 g/kg/day [Cahen 1964].

Inhibition of hERG Channel
An extract (dichlormethane/ethanol; not further specified) did not show inhibitory activity in a hERG (human Ether-a-go-go Related Gene) screening based on semi-automated voltage-clamp system using *Xenopus* oocytes [Kratz 2016].

Clinical safety data
Over 500 individuals have participated in open and controlled studies with fumitory aqueous dry extracts (not further specified), taking 750-1500 mg/day for up to 6 months. The tolerability of the treatments was very good [Salembier 1967; Devin 1969; Heully 1969; Zacharewicz 1979; Fiegel 1971; Fablet 1963; Colson 1967; Dornier 1968; Roux 1967, 1977; Warembourg 1967]. Minor adverse events occurred in a very few cases involving gastrointestinal discomfort and/or an allergic reaction with pruritis [Fablet 1963; Roux 1967].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

GENTIANAE RADIX

2014

Gentian Root

DEFINITION

Gentian root consists of the dried, fragmented underground organs of *Gentiana lutea* L.

The material complies with the monograph of the European Pharmacopoeia [Gentian root].

CONSTITUENTS

Secoiridoids including gentiopicroside (1-4%) and amarogentin (0.025-0.4%); lignans, triterpenoids, oligosaccharides including gentianose and gentiobiose; xanthones (ca. 0.1%), mainly gentisin, isogentisin and gentioside; and traces of essential oil [Atkinson 1969; Bricout 1974; Franz 1975, 1978; Quercia 1980; Sticher 1980; Takino 1980; Chialva 1986; Nikolaeva 1983; Rossetti 1984; Hayashi 1988; Buffa 1991; Krupinska 1991; Kakuda 2003; Toriumi 2003; Ando 2007; Blaschek 2009].

CLINICAL PARTICULARS

Therapeutic indications

As a bitter in loss of appetite e.g. after illness; dyspeptic complaints [Gentiana BHP 1983; Wegener 1998; Meier 2007; Schilcher 2010]

Posology and method of administration

Dosage

Adults: 0.1-2 g of drug in 150 mL of water in infusion, decoction or maceration, up to 3 times daily. Tincture (1:5, ethanol 45-70 % V/V): average single dose of 1 ml, up to 3 times daily. Hydroethanolic extracts of equivalent bitterness value [Wegener 1998; Meier 2007].
Children, average daily dose: 4-10 years of age, 1-2 g of drug; 10-16 years, 2-4 g; in ethanol-free dosage forms [Dorsch 2002].
The dosage may be adjusted according to the bitterness sensitivity of the individual [Henschler 1966; Meier 2007].

Method of administration
For oral use in liquid preparations; for loss of appetite, a single dose administered half to one hour before a meal; in dyspeptic complaints, a single dose after the meal [Wichtl 1999; Meier 2007].

Duration of administration
No restriction. If symptoms persist, consult your doctor.

Contraindications
Gastric or duodenal ulcers; hyperacidity [Fintelmann 2009; Meier 2007; Schilcher 2010].

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
In accordance with general medical practice, the product should not be used during pregnancy without medical advice [Duke 1985].

Effects on ability to drive and to use machines
None known.

E/S/C/O/P MONOGRAPHS

Undesirable effects
Occasional headaches may occur [Meier 2007; Schilcher 2010].

Overdose
Overdose may lead to nausea or vomiting [Meier 2007].

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments
An aqueous extract from gentian root directly stimulated acid secretion in cultured cells from rat gastric mucosa, causing a concentration-dependent 1.7-fold acid increase at 100 µg/mL ($p<0.01$) [Gebhardt 1997].

Selective antifungal activity of gentian root extracts has been reported [Meier 2007].

Gentian root extract was reported to stimulate phagocytic activity of human leukocytes indicating possible immunostimulatory activity [Schmolz 1992].

A methanolic dry extract (2:1) was found to have significant stimulatory effects on mitotic activity of cultured chicken embryonic fibroblast cells ($p<0.10$). The extract increased the number of polygonal fibroblasts. The number of collagen granules in the embryonic fibroblasts was significantly increased ($p<0.01$); the percentage of vacuole-containing cells and round cells was significantly decreased ($p<0.005$) [Öztürk 2006].

Ethanol (yield 32%) and water (yield 18%) extracts moderately inhibited rat lens aldose reductase and human recombinant aldose reductase, while methanol (yield 38%) and ether (yield 5%) extracts demonstrated greater inhibitory activity with IC_{50} values of 112±15, 79±12 µg/mL (rat) and 23±5, 36±5 µg/mL (human), respectively [Akileshwari 2012].

Accumulation of sorbitol in red blood cells under high glucose load was assessed. An inhibition of 35% was achieved by 100 µg/mL of the aqueous extract and by 50 µg/mL of the methanol extract. The ether extract showed 52% inhibition at 50 µg/mL and 63% inhbition at 100 µg/mL ($p<0.05$) [Akileshwari 2012].

Among the methanol, hydroethanolic (96%, 75%, 50% and 25% v/v) and aqueous extracts investigated the 50% hydroethanolic extract showed the greatest activity, inhibiting 71% of human neutrophil myeloperoxidase after 10 min, and inducing almost 100% inhibition of myeloperoxidase after 15 min of exposure. Of the constituents tested, gentiopicroside showed the highest level of inhibition (IC_{50}=0.8±0.1 µg/mL), followed by amarogentin (IC_{50}=2.4±0.1 µg/mL) [Nastasijevic 2012].

In the DPPH test a 50% hydroethanolic extract showed anti-radical activity with an IC_{50} value of 20.6 µg/mL [Nastasijevic 2012].

In an ex vivo study nine healthy volunteers (three males and six females, age 35-50 years) received a single oral dose of 15 g of a 30% ethanolic extract of *Gentiana lutea*. Sera and peripheral blood mononuclear cells (PBMC) were extracted from blood samples taken before, and 2 h after the consumption of the extract. The PBMC were re-incubated in the serum they were extracted with for another hour and subsequently exposed to X-ray radiation (0 Gy, 6 Gy and 8 Gy). Radioresistance of the PBMC was increased in most subjects when isolated from the serum after Gentian extract consumption [Menkovic 2010].

In vivo experiments

Gastric and choleretic activity
In general, the bitter principles of gentian root stimulate secretion of gastric juice and bile and thereby enhance appetite and digestion [Schmid 1966; Paris 1971].

Gentian tincture administered orally to dogs, using a method which prevented the tincture reaching the stomach, increased secretion of gastric juice by 30% compared to untreated animals [Meier 2007].

Gentian root extract (equivalent in bitterness value to 200 Ph. Helv. VI units/g), administered intragastrically to anaesthetized rats, increased gastric secretion dose-dependently (12%, 27% and 37% above controls). Moreover, pH did not change at concentrations of 0.25% and 1% but increased from 4.25 to 4.85 at 4%. A dose of 0.5 mL/kg did not affect the incidence of gastric ulceration in rats with pyloric ligation [Leslie 1978]. In pylorus-ligated rats, duodenal administration of the methanolic extract, as well as the ethylacetate and butanol fractions, suppressed gastric juice secretion and total acid output in a dose-dependent manner, but not the total pepsin output. Administration of the extract and fractions resulted in a dose-dependent protective effect against gastric ulcers induced by acetylsalicylic acid plus pyloric ligation (ID_{50} values: 892, 126 and 137 mg/kg respectively). The protective effects of the ethylacetate fraction at 250 mg/kg and butanol fraction at 500 mg/kg were almost equivalent to 60 mg/kg cimetidine. Oral administration of the fractions as well as of amarogentin, gentiopicroside, amaroswerin and swertiamarin exerted dose-dependent protective effects against gastric ulcers induced by immersion stress (ID_{50} values for amarogentin, amaroswerin and swertiamarin: 5.76, 2.58 and 167 mg/kg respectively).The protective effect of gentiopicroside at 250 mg/kg equivalent to 1000 mg/kg of butanol fraction was 26.5%. Oral administration of the fractions, as well as amarogentin, gentiopicroside, amaroswerin and swertiamarin, showed protective effects against gastric ulcers induced by ethanol. 125 mg/kg of the ethylacetate fraction, 5.0 mg/kg of amarogentin, 5.0 mg/kg of amaroswerin and 20 mg/kg of swertiamarin decreased the ulcer index by 24.2%, 33.7%, 45.4% and 30.8%, respectively [Niiho 2006].

An ethanolic extract was administered intraduodenally to rats at 500 mg/kg b.w. daily, for 2 days prior to and 1 day after i.p. administration of carbon tetrachloride. Bile flow impaired by CCl_4 significantly increased in comparison with untreated control rats treated with CCl_4 only ($p<0.005$) and also in comparison with those which received neither CCl4 nor the extract ($p<0.01$), suggesting that the extract had choleretic activity [Öztürk 1998].

Other effects
Bronchosecretion in rabbits was elevated in comparison with control animals after administration of extract directly to the stomach by gavage for 3 days (at the equivalent of 12.6 mg/kg/day of dried root) [Chibanguza 1984].

A methanolic extract (2:1) was investigated for effects on the central nervous system of mice. Both 250 mg/kg ($p<0.05$) and 500 mg/kg ($p<0.10$) i.p. administration led to a significant increase in the swimming time of mice compared to control. Both doses also significantly increased ($p<0.05$) the latency of tail clip responses compared to control. Whereas latency in the tail immersion test decreased significantly in mice given 250 mg/kg ($p<0.005$) and 500 mg/kg ($p<0.01$) [Öztürk 2002].

Gentiopicroside significantly inhibited the production of TNF in models of hepatic injury in mice after i.p. administration at

30 mg/kg b.w./day ($p<0.05$) or 60 mg/kg b.w./day ($p<0.01$) for 5 days [Kondo 1994].

Gentiopicroside was administrated intragastrically to mice at 50, 100 and 200 mg/kg b.w. twice daily for 3 days. Doses of 100 and 200 mg/kg significantly ($p<0.05$ and $p<0.01$ respectively) reduced mechanical allodynia caused by complete Freund's Adjuvant (CFA)-induced inflammation in the left hind-paw. Further investigations (including recordings at the anterior cingulate cortex (ACC), confirmed that NMDA NR2B receptors mediated this gentiopicroside inhibition of peripheral inflammation, responding in a dose-dependent manner, Western blot analysis of total ACC homogenates showed that NR2B, but not NR2A, subunit expression was significantly reduced in CFA-injected mice treated with gentiopicroside (100 mg/kg) (182.1±32.5%; $p<0.05$ compared to CFA-injected mice). Moreover, gentiopicroside decreased cAMP levels in the ACC of mice by 20.3±2.8 pmol/mg, 16.5±2.6 pmol/mg, and 14.7±2.1 pmol/mg at doses of 50, 100 and 200 mg/kg respectively ($p<0.05$ compared to CFA-injected mice) or *in vitro* (slice incubation with 10 mM for 4-6 h) acting as an adenyl cyclase inhibitor. Gentiopicroside had no effect on the basal excitatory or inhibitory synaptic transmission [Chen 2008].

Pharmacological studies in humans

Patients with inflammatory conditions of the gastrointestinal tract, ulcerative colitis (n = 8), Crohn's disease (n = 2) and non-specific inflammatory disorders (n = 9), who had elevated secretory immunoglobulin (sIgA) levels (20-200 mg/dL) in their saliva, were treated with gentian root tincture (3 × 20 drops/day) for 8 days. A group of 8 healthy individuals (sIgA levels of 3-25 mg/dL) was treated in the same way. Apart from two patients in whom sIgA increased, sIgA levels steadily declined in both groups [Zimmermann 1986].

Secretion of gastric juice in 10 healthy individuals was stimulated after one oral dose of alcoholic gentian root extract equivalent to 0.2 g of dried root. In the same experiment emptying of the gall bladder, observed using X-ray contrast, was increased and prolonged; this was interpreted as a cholagogic effect [Glatzel 1967].

Clinical studies

In an open study, 205 patients with various dyspeptic symptoms (heartburn, vomiting, stomach aches, nausea, loss of appetite, constipation, flatulence) were treated with a dry hydroethanolic extract (5:1) at a dosage of 240 mg twice or three times daily (average daily dose 576 mg of extract, equivalent to 2.9 g of dried root) for about 15 days. Improvements in symptoms were evident after 5 days in most cases and by the end of the study the average level of improvement was 68%. The efficacy of the preparation was assessed by the doctors as excellent (symptoms eliminated) in 31% of patients, good in 55%, moderate in 9% and inadequate in 5% of cases [Wegener 1998].

Pharmacokinetic properties

Metabolic conversion of gentiopicroside was demonstrated *in vitro*, using human intestinal bacteria. Gentiopicroside anaerobically incubated with *Veillonella parvula* ssp. *parvula*, produced five metabolites which were identified as erythrocentaurin, gentiopicral, 5-hydroxymethylisochroman-1-one, 5-hydroxymethyl-isochromen-1-one and *trans*-5,6-dihydro-5-hydroxymethyl-6-methyl-1*H*,3*H*-pyrano[3,4-c] pyran-1-one [El-Sedawy 1989].

The pharmacokinetics and bioavailability of gentiopicroside from gentian decoctions and gentiopicroside alone were compared after oral administration to rats. The doses were adjusted to deliver equivalent amounts of gentiopicroside (150 mg/kg b.w.). The bioavailability of gentiopicroside from the decoction was markedly higher than gentiopicroside alone (AUC of 70.0±13.9 µg h/mL compared to 32.7±12.9 µg h/mL). Changes in plasma levels of gentiopicroside following oral administration of gentiopicroside alone or from the decoction showed elimination half times ($T_{(1/2)Ke}$) of 3.35 ± 0.76 h and 6.21 ± 3.07 h, respectively. The mean maximum concentrations of gentiopicroside at 0.75-1.6 h after the administration of gentiopicroside or decoction were 5.78 and 10.53 µg/mL respectively. The relative bioavailability of gentiopicroside from the decoction was 214% in comparison to gentiopicroside alone [Wang 2007].

After 60 min reperfusion following liver ischaemia, rats received a single i.v. dose of gentiopicroside (5 mg/kg b.w.) to investigate the influence of liver ischemia/reperfusion on the pharmacokinetics of gentiopicroside. The control group without liver ischemia received the same dose of gentiopicroside. Compared to control, a significant increase ($p<0.05$) of the AUC was found (564.7±95.1 min µg/mL and 801.2±87.4 min µg/mL, control and ischemia/reperfusion group respectively). However, the clearance (Cl) was significantly ($p<0.05$) decreased in the liver of ischemia/reperfusion group. Furthermore, to determine hepatic CYP enzyme involvement in the metabolism of gentiopicroside in rats, the rats were pretreated with a non-specific hepatic CYP inhibitor (SKF-525A). Gentiopicroside levels were increased and the clearance was decreased in the group pretreated with SKF-525A compared to the group of gentiopicroside alone (5 mg/kg i.v.), AUC was found as 564.7±95.1 min µg/mL in the group of gentiopicroside alone and 1148.6±254.2 min µg/mL ($p<0.05$) in the group pretreated with SKF-525A. The rats were given a single dose of drug (5 mg/kg i.v. and 100mg/kg p.o.) to determine the bioavailability of gentiopicroside. The average AUC values were 564.7 and 1162.9 min µg/mL in the i.v. and the oral groups respectively. Based on the equation of oral bioavailability, bioavailability of gentiopicroside was found to be approximately 10.3% [Chang-Lio 2012].

Preclinical safety data

Acute toxicity

In mice, an acute oral LD_{50} of 25 mL/kg was determined for two gentian extracts (30% or 37% ethanol, bitterness value of 200 Ph. Helv. units/g) [Leslie 1979].

Repeated dose toxicity

Rabbits treated with 12.6 mg/day of gentian extract for 3 days did not exhibit symptoms of toxicity or abnormal clinical serum parameters with the exception of a slightly reduced number of erythrocytes in the treatment group compared to a control group [Chibanguza 1984].

Subchronic toxicity

No treatment-related adverse effects were observed in rats treated orally for 13 weeks with 1.6 mL/kg of a combination product containing alcoholic extracts of gentian root, chamomile and liquorice. No effect was observed on reproduction, fertility or mating performance in female rats, and no teratogenic effect was observed in rabbits [Leslie 1979].

Mutagenicity

Gentian root extracts and isolated minor constituents showed weak mutagenicity in the Ames test with *Salmonella typhimurium* strains TA 97, 98, 100 and 2637 activated with S9 enzyme mixture [Morimoto 1983; Göggelmann 1986; Matsushima 1985; Meier 2007]. Mutagenic activity of the extract was attributed to low levels of the xanthones gentisin and isogentisin. Isogentisin and other xanthones in gentian root have a striking structural resemblance to quercetin, a well known mutagen in food, which

is reported to be non-carcinogenic and considered to be safe [Fintelmann 1988; Bertram 1989; Meier 2007].

Clinical safety data
From a total of 205 patients who received on average 576 mg of a dry hydroethanolic extract (equivalent to 2.9 g of dried gentian root), for 15 days, only 5 (2.4%) reported mild adverse effects such as flatulence, stomach cramp, nausea or headache [Wegener 1998].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

Board of Directors of ESCOP

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

GINSENG RADIX

2023

Ginseng

DEFINITION

Whole or cut dried root, designated white ginseng; treated with steam and then dried, designated red ginseng, of *Panax ginseng* C. A. Mey. It contains not less than 0.40 per cent for the sum of ginsenosides Rg1 ($C_{42}H_{72}O_{14}.2H_2O$; Mr 837) and Rb1 ($C_{54}H_{92}O_{23}.3H_2O$; M_r 1163) (dried drug).

The material complies with the monograph of the European Pharmacopoeia [Ginseng].

CONSTITUENTS

Triterpene saponins, mainly tetracyclic dammarane-type. Examples of protopanaxadiol saponins are: ginsenosides Ra1, Ra2 and Ra3; ginsenosides Rb1, Rb2 and Rb3; ginsenosides Rc and Rd; and malonyl-ginsenosides Rb1, Rb2, Rc and Rd. Examples of protopanaxatriol saponins are: ginsenosides Re and Rf; 20-gluco-ginsenoside Rf; ginsenosides Rg1, Rg2 and Rh1) and pentacyclic oleanane-type (ginsenoside Ro). The ginsenosides considered the most important are ginsenosides Rb1, Rb2, Rc, Rd, Re, Rf, Rg1 and Rg2, with Rb1, Rb2, Re and Rg1 being the most abundant. The total ginsenoside content of a 6-year-old main root varies between 0.7 and 3%. The lateral roots can contain two to three times more saponins than the main root while the slender roots can contain up to 10 times more [Soldati 1979; Sticher 1979; Shibata 1985; Sprecher 1987; Tang 1992; Schweins 2018; Bruneton 1995; Cui 1995; Corthout 1999; Ma 2005; Richter 2005; Bauer 2016; Chung 2017; Ali 2017; Xiong 2017; Li 2019].

Other constituents include peptidoglycans called panaxans, acetylenic compounds such as panaxynol, pyrazine derivatives such as 3-*sec*-butyl-2-methoxy-5-pyrazine, oligo- and polysaccharides, phenolic compounds such as vanillic acid and salicylates, and traces of essential oil containing sesquiterpenes such as eremophilene [Sprecher 1987; Tang 1992; Cho 2015; Lee SM 2015].

In general, for white ginseng the protopanaxadiol type ginsenosides (Rb2, Rb3, Rc, Rd, Re1, F2, Ro) as well as protopanaxatriol type ginsenosides (Re, Rf, Rg1, Noto-R1) are relatively more abundant. Malonyl ginsenosides mRa1/Ra2, mRa3, mRb1, mRb2, mRb3, mRc, mRd, mRe and mRg1 are considered to be characteristic components that are decreased by processing. Conversely, ginsenosides (20S- and 20R-) Rg3, Rh1, and Rh2 are considered to be characteristic components of red ginseng. Higher levels of protopanaxadiol type ginsenosides (Ra1, Ra2 and Ra3, Rb1) and protopanaxatriol type ginsenosides (Rg4) are also found in red ginseng [Shibata 2001, Wu 2015, Zhang 2012, He 2018].

CLINICAL PARTICULARS

Therapeutic indications

Decreased mental and physical capacities such as weakness, exhaustion, tiredness and loss of concentration, as well as during convalescence [Forgo 1981a, 1983, 1985; Hallstrom 1982; D'Angelo 1986; Van Schepdael 1993; Kim 2006; Schott 2006; Lee N 2016].

Posology and method of administration

Dosage

Adult daily dose: 0.5 g up to a maximum of 2 g of dried root; equivalent preparations [Forgo 1981a; Hallstrom 1982; Van Schepdael 1993; Kim 2006; Schott 2006; Lee N 2016, Schweins 2018].

Method of administration

For oral administration.

E/S/C/O/P MONOGRAPHS

Duration of administration
If symptoms persist or worsen after one month, medical advice should be sought.

Contraindications
None known.

Special warnings and precautions for use
Do not exceed the recommended dose.

Diabetics should consult a physician prior to taking ginseng root [Sotaniemi 1995].

Interaction with other medicaments and other forms of interaction
Ginseng intake may slightly reduce blood glucose levels [Sotaniemi 1995, Buettner 2006]. Interaction of ginseng with warfarin is possible [Janetzki 1997, Dong 2017].

Pregnancy and lactation
In accordance with general medical practice, ginseng should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Rare cases of allergic reactions, hypoglycaemia [Adusumilli 2002; Wiwanitkit 2004; Lee 2006, Kim 2008].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Cell proliferation
Red ginseng extract (0.52 mg/g ginsenoside Rg1 and 4.03 mg/g ginsenoside Rb1) at concentrations of 200 or 300 µg/mL caused significant ($p<0.05$) suppression of PMA-induced cell motility and invasion in SW480 human colon cancer cells. The extract also inhibited the PMA-induced matrix metallopeptidase-2 (MMP-2) and MMP-9 activity, as well as their protein and mRNA expression, in a dose-dependent manner in the SW480 cells [Seo 2011].

An extract (not further specified) facilitated the early differentiation of human embryonic stem cells into mesendoderm lineage cells [Kim 2011].

An aqueous extract (not further specified) of Korean red ginseng exerted a dose-dependent inhibitory effect on the invasion and motility, but not adhesion, of highly metastatic SK-Hep1 cells without causing cytotoxicity. Zymographic analyses revealed downregulating effects on MMP-2, MMP-9 and uPA activities in SK-Hep1 cells. Western blot analyses also showed dose-dependent decreases in MMP-2 and MMP-9 protein expressions, increased levels of tissue inhibitor of matrix metalloproteases 1, tissue inhibitor of matrix metalloproteases 2 and type-1 plasminogen activator inhibitor [Ho 2012].

Cytotoxicity of a ginseng extract (not further specified) was measured by MTT assay after exposure of MDA-MB-231, MCF-10A and MCF-7 breast cancer cells to concentrations of 0.25, 0.5, 1, 1.5, 2 and 2.5 mg/well. The treatment resulted in inhibition of cell proliferation in a dose- and time-dependent manner. The p53, p21WAF1 and p16INK4A expression levels were up-regulated in ginseng-treated MDA-MB-231 and MCF-7 cancer cells compared to untreated controls and in MCF-10A cells [Al Shabanah 2016].

An extract (not further specified) activated caspase-3 in human renal carcinoma cell lines and promoted apoptosis by cleaving poly(ADP-ribose) polymerase which abolished the expression of B-cell lymphoma 2, B-cell lymphoma-extra large, survivin, inhibitors of apoptosis proteins-1/2, cyclooxygenase-2, cyclin D1, MMP-9, and vascular endothelial growth factor as well as upregulating pro-apoptotic gene products [Kim C 2017].

The effects of an ethanolic extract (70%, not further specified) on cell proliferation, apoptosis and hair growth were observed using cultured outer root sheath (ORS) keratinocytes and human hair follicles with or without Dickkopf-1 application. The extract significantly ($p<0.05$) stimulated proliferation and inhibited apoptosis in ORS keratinocytes. The extract antagonized the effect of Dickkopf-1-induced catagen-like changes of hair follicles [Lee Y 2017].

The major metabolite of Rb1, 20-O-β-D-glucopyranosyl-20(S)-protopanaxadiol (GPD), was tested using SK-MEL-28 cells. Cells were treated with or without 20 µM, 40 µM, 60 µM of GPD or 60 µM of Rb1. GPD significantly inhibited cell growth at 40 µM ($p<0.0001$) and 60 µM ($p<0.001$). Incubation with 40 µM GPD induced the autophagic markers LC3-II, p62/sQSTM1 and Beclin-1. This dose also significantly ($p<0.005$) induced apoptosis, increased DNA fragmentation and caused higher expression of the cleaved forms of PARP, caspase-3, caspase-7 and caspase-9 [Kang 2014].

Cultured human dermal fibroblasts were treated with 0, 1, 10 and 100 ng/mL and 1 and 10 µg/mL of ginsenoside Rb1. At 10 ng/mL to 1 µg/mL cell proliferation increased significantly ($p<0.05$). Collagen synthesis was significantly ($p<0.05$) augmented at 1 ng/mL to 1 µg/mL [Lee GY 2016].

Effects on angiogenesis
In human umbilical vein endothelial cells (HUVECs), ACE activity was reduced after 10 min incubation with an aqueous extract (4% ginsenosides) at concentrations of 5.0 and 10.0 mg/mL. This effect was additive with the ACE inhibitor enalaprilat. No effect was seen on NO production. Angiotensin I-induced contraction of bovine mesentheric arteries was attenuated by 0.1 and 0.5 mg/mL of the extract, while no endothelium-dependent or -independent relaxation was seen [Persson 2006].

An ethanolic extract (yield 4.76%; 82.65% ginsenosides) stimulated tube formation at 10 µg/mL in HUVECs, while higher concentrations increased tube formation in a dose-dependent manner. Treatment of HUVECs with the extract resulted in dose- and time-dependent increases in ERK1/2 phosphorylation as well as time-dependent increases in Akt and eNOS phosphorylation. NO production was increased in HUVECs treated with the extract when compared with control, an effect abolished by the addition of N(G)-monomethyl-L-arginine. The extract-mediated increase in ERK phosphorylation was abolished by treatment with wortmannin (phosphatidylinositol 3-kinase inhibitor) and PD98059 (MEK inhibitor) but was only partially suppressed by the addition of N(G)-monomethyl-L-arginine [Kim 2007].

Neuroprotection
Treatment with 500 µg/mL of an aqueous extract (not further specified) protected neuronal cells from apoptosis mediated by PCB 52, attenuated lipid peroxidation, generation of ROS and DNA fragmentation, and reduced the PCB 52-induced

proteolytic cleavage of β-catenin and poly(ADP-Ribose)-polymerase [Lee JY 2004].

An aqueous extract (not further specified) increased cell viability of primary rat astrocytes in a stress model generated by H_2O_2. Exposure of astrocytes to H_2O_2 decreased the activities of CAT, SOD, glutathione peroxidases (GPx) and glutathione reductase (GR), and increased ROS formation. The extract reversed almost all of these effects in the H_2O_2-injured primary cultures [Naval 2007].

An extract (4.37% ginsenosides) inhibited kainic acid-induced excitotoxicity in a dose-dependent manner. The extract also inhibited the intracellular ROS and $[Ca^{2+}]i$ elevation in hippocampal cells in a concentration-dependent manner [Han 2012].

An aqueous extract (not further specified) of Korean red ginseng inhibited neuronal damage and generation of intracellular ROS induced by excitatory amino acids, such as glutamate and N-methyl-D-aspartate (NMDA), or by Aβ (25-35) in primary cultured rat cortical cells. The extract increased phosphorylation of Bad at Ser 112 and inhibited Bax expression and caspase 3 activity. It also inhibited DNA fragmentation induced by NMDA or Aβ (25-35) and β-secretase activity [Kim 2014].

A fraction from an 80% ethanolic extract at 100 µg/mL prevented serum deprivation-induced PC12 cell apoptosis through the PKA/CREB pathway [Lin 2009].

Activation of biosynthesis
A standardized extract (4% ginsenosides) stimulated D-glucose transport in Ehrlich ascites tumour cells and D-glucose uptake in rabbit cerebral cortical tissue [Hassan Samira 1985; Yamasaki 1993].

After addition of a 70% methanolic extract (yield 37-43%) to rat primary hepatocytes, upregulation of CYP7A1 mRNA and protein levels was observed [Kawase 2013]. The extract at 100 and 500 µg/mL resulted in upregulation of CYP8B1 and MRP2 mRNA. Ginsenoside Re enhanced the mRNA level of CYP8B1, whereas ginsenosides Rb2 and Rg2 enhanced MRP2 mRNA levels [Kawase 2014].

Immunomodulation
The mitogenic activity and anticomplement activity of a standardized extract (4% ginsenosides) and several fractions were tested in mice spleen cell cultures. The extract possessed anticomplement and mitogenic activities while the strongest anticomplement activity was observed with a crude polysaccharide fraction consisting of arabinose, galactose and glucose with small amounts of galacturonic acid, glucuronic acid and rhamnose; its molecular weight was estimated to be 3.68×10^5 kD [Yamada 1995].

Peripheral blood mononuclear cells from healthy volunteers (n=20) or from patients with chronic fatigue syndrome (n=20) or AIDS (n=20) were tested, in the presence or absence of varying concentrations of an extract (not further specified), for natural killer cell activity against K562 cells and for antibody-dependent cellular cytotoxicity against human herpes virus 6-infected H9 cells. The extract at concentrations of 1, 10 and 100 µg/mL significantly ($p<0.05$ to $p<0.001$) enhanced the cellular immune function of peripheral blood mononuclear cells from all groups [See 1997].

An extract (not further specified; 1-62 µg/mL) demonstrated a considerable increase in IL-12 production in human serum, whereas IL-10 production was unchanged for all concentrations. An IL-12 peak was observed at around 4 µg/mL, giving increases of 6- to 146-fold. Concentrations above 1 µg/mL resulted in higher IL-12 production [Larsen 2004].

The phagocytic capacity of polymorphonuclear cells and monocytes, but not peripheral blood mononuclear cells, was enhanced by an extract standardized to ginsenosides [Kang 2008].

In a cell proliferation assay, an extract (not further specified) enhanced the proliferation of RAW 264.7 macrophages and protected against cell regression in macrophages treated with methotrexate. The extract induced the production of NO and the expression of inducible NOS and COX-2 mRNA. Furthermore, it enhanced the production of cytokines including IL-1α, IL-1β, IL-6, TNF-α and granulocyte-macrophage colony-stimulating factor as well as chemokines such as macrophage chemotactic protein-1. No changes were seen in normal T-cells, regardless of methotrexate co-administration [Jang 2010].

An extract (not further specified) partially protected human epithelial cells from respiratory syncytial virus (RSV)-induced cell death and viral replication. It also inhibited the production of RSV-induced pro-inflammatory cytokine (TNF-α) in murine dendritic and macrophage-like cells [Lee JS 2015].

An aqueous extract (not further specified) increased IgA production by LPS-stimulated B cells. Ginsenoside Rg1 and 20(S)-Rg3 induced IgA production and expression of GLTα transcripts by LPS-stimulated B cells [Park 2015].

Ex vivo experiments

Antioxidant properties
In experiments with perfused rabbit lungs, an extract (not further specified) inhibited vasoconstriction induced by the thromboxane analogue U46619 or by acetylcholine after exposure to free radicals generated by electrolysis. The extract was superior to pure ginsenosides [Rimar 1996; Gillis 1997].

Two groups of 5 rats were given an extract (not further specified) at 10 mg/mL in drinking water (corresponding to 1.6 g/kg/day) for one week, then one group was exposed to hyperbaric 100% oxygen (HBO) for 6 hours. Control groups received water only and water only with exposure to HBO, respectively. Isolated perfused hearts from the rats were subjected to mild ischaemia and then reperfused. The extract prevented myocardial ischaemia/reperfusion damage and the impairment of endothelial functionality induced by ROS arising from HBO exposure [Maffei Facino 1999].

Immunomodulation
After oral administration of a standardized extract (not further specified) to mice at 10 mg/day for 4 consecutive days, the effects on immune response were investigated. The extract enhanced the antibody plaque forming cell response and circulating antibody titre against sheep erythrocytes [Singh 1984].

The above finding was confirmed by experiments involving oral administration to mice of an aqueous extract with a defined ginsenoside content (0.58% ginsenosides). Administration at 10, 50 or 250 mg/kg b.w. daily for 5-6 days resulted in enhanced immune responses in a battery of six *ex vivo* tests which included primary and secondary immune response against sheep red cells, natural killing activity, mitogen-induced proliferation, interferon production and T-cell mediated cytotoxicity [Jie 1984].

Other effects
An extract (not further specified; 1-40 mg/mL) showed a dose-

dependent relaxation of isolated corpus cavernosum tissues of New Zealand white rabbits precontracted by phenylephrine [Choi 1998].

An extract (4% ginsenosides) reduced maximal proliferation of rat smooth muscle cells to 24% of control values and antagonized norepinephrine-induced maximal vasoconstriction of rat aorta by 21% and 44% at concentrations of 1.44 mg/mL and 2.88 mg/mL of the extract respectively *in vitro*. In rats treated orally with either 2 mg/kg or 200 mg/kg of the extract for 7 days prior to a carotid artery balloon injury, the neointima-to-lumen area ratio was significantly ($p<0.01$) reduced compared to control [Wu 2001].

The protective effect of an extract (26.1% ginsenosides) against ischaemia/reperfusion injury in isolated guinea pig hearts was evaluated. The animals were pre-treated with 250 or 500 mg/kg of extract p.o. for 14 days prior to excision. Ischaemia was induced in the excised hearts for 60 min, followed by 120 min reperfusion. The extract increased haemodynamic parameters such as aortic flow, coronary flow and cardiac output as well as left ventricular systolic pressure, the maximal rate of contraction and maximal rate of relaxation. Moreover, the extract improved electrocardiographic indices such as the QRS, QT and RR intervals, suppressed LDH, creatine kinase-MB fraction and cardiac troponin I and ameliorated MDA and glutathione [Lim 2013].

In vivo experiments

Hormonal effects
Estradiol valerate was used to induce polycystic ovaries in female Sprague-Dawley rats. Sixty days following induction, the rats were left untreated (control) or administered orally for 60 days with either saline or an extract of Korean ginseng (not further specified; 200 mg/kg b.w). The numbers of corpora lutea and corpora albicantia were higher in the treatment group than in the control group, while the number of cystic follicles was lower. Nerve growth factor (NGF) is considered a factor in the pathogenesis of PCOS: the induced increase in NGF-mRNA was significantly ($p<0.05$) attenuated in the treatment group compared to control. Likewise, the concentration of NGF protein was significantly ($p<0.05$) lower in the treatment group [Jung JH 2011].

Intraperitoneal administration of ginseng saponin fractions to rats stimulated adrenocorticotrophic hormone (ACTH) secretion from the hypothalamus/hypophysis, leading to increased corticosterone synthesis and excretion [Hiai 1979a, 1979b].

Effects on performance
After oral administration of an extract (not further specified), rats were subjected to learning and memory retention tests, and ^{14}C-phenylalanine transport across the blood-brain barrier was also determined. After i.p. injection with the extract, the brain stem and brain cortex were analyzed for concentrations of monoamines and 3',5'-cyclic adenosine monophosphate (AMP), and for the activity of phosphodiesterase and adenylate cyclase. The following results were obtained [Petkov 1978]:

- Improved learning and memory retention (5 of 7 tests) after oral administration at 20 mg/kg b.w. for 3 days, but unchanged or even decreased learning and memory retention (4 of 7 tests) after 100 mg/kg for 3 days.
- Increased ^{14}C-phenylalanine transport across the blood-brain barrier after 30 mg/kg p.o. for 5 days.
- Unchanged phosphodiesterase activity in brain stem and cortex after 50 mg/kg i.p. for 5 days.
- Decreased adenylate cyclase activity (with or without NaF-activation) after 30 mg and 200 mg/kg i.p. for 5 days, except after 30 mg without NaF-activation when adenylate cyclase activity was increased.
- Decreased 3',5'-cyclic AMP concentration in brain stem and cortex after 200 mg/kg i.p. for 5 days.
- Increased dopamine and noradrenaline concentrations in brain stem, whereas the serotonin concentration was decreased in brain stem and increased in brain cortex, after 50 mg/kg i.p. for 5 days [Petkov 1978].

The effects of a hydroalcoholic extract with a standardised level of saponins (not further specified) on resistance to stress and exhaustion were measured using a cold stress test in normal and adrenalectomized rats and a forced swimming test in mice, with tests comparing acute and subacute dosing and oral and i.p. administration. Physiological and biochemical tests (body weight increase, food and water consumption, urine analysis for sodium, potassium and chloride, liver proteins, total cholesterol, total lipids and triglycerides, adrenal total cholesterol, blood and serum glucose, triglyceride and cholesterol values) were also carried out. Significant ($p<0.05$) effects seen in this study were [Bombardelli 1980]:

- Time to exhaustion was significantly prolonged in mice following a single i.p. administration of the extract at doses equivalent to 7.5 and 37.5 mg/kg ginseng total saponins, and in mice administered 37.5 mg/kg/day p.o. for 15 days.
- A single i.p. dose of extract (equivalent to 3.75 mg/kg ginseng total saponins) significantly attenuated the body temperature decline in cold stressed normal rats but not adrenalectomized rats as compared to controls (saline). Hydrocortisone (10 mg/kg i.p.) significantly attenuated the cold stress-induced temperature decline in adrenalectomized rats but not normal rats.
- Body temperature decline under cold stress in rats was significantly attenuated after i.p. administration of the extract (single dose, 3.75 mg/kg ginseng total saponins) compared to controls receiving saline solution. Hydrocortisone (10 mg/kg) did not show this activity. In adrenalectomized rats, the extract did not have cold-protective activity whereas hydrocortisone did.
- In weanling rats, the fresh weight of thymus was dose-dependently reduced after i.p. administration of the extract for 4 days at doses corresponding to 1.5-30 mg/kg of ginseng total saponins.

Liver protein, total cholesterol and total lipids were reduced in male and female rats after 15 days of i.p. administration of the extract at doses corresponding to 3 or 30 mg/kg/day ginseng total saponins (some but not all results were significant, $p<0.05$). Such changes were not seen after oral administration of extract doses corresponding to 1.87 or 37.5 mg/kg/day ginseng total saponins except for a reduction of liver protein in female rats receiving the higher oral dose. Adrenal total cholesterol was markedly reduced only in orally treated animals. Furthermore, body weight was monitored weekly in a prolongation of the same experiment comparing 5 weeks oral administration with 4 weeks i.p. administration. Growth retardation was seen in male rats after both oral and i.p. treatment but was stronger and dose-dependent after i.p. treatment. In female rats weak and non-dose-dependent growth retardation was only seen after i.p. treatment [Bombardelli 1980].

Male Swiss mice (7 weeks old) received, as their only liquid for up to 96 days, either distilled water or an infusion (not further

specified) from ginseng corresponding to 33 mg dry root/mL. The average consumption per mouse corresponded to 274 mg root daily. No significant differences between treatments were seen in weight gain or in the cold swimming test after 35, 46 or 96 days [Lewis 1983].

Pre-treatment of rats with a 1% methanolic extract (not further specified; 20 mg/kg b.w. i.p. twice with a 24-hour interval) led to significant differences in energy metabolism after exercise (swimming for 30 or 60 minutes) as measured by plasma concentrations of relevant metabolites. Glucose was higher ($p<0.01$) and free fatty acids were lower ($p<0.01$) after 30 minutes, whereas pyruvic acid ($p<0.05$) and lactic acid ($p<0.01$) were significantly lower after 60 minutes of exercise as compared to saline-treated controls [Avakian 1984].

The effects of an extract (not further specified) administered i.p. to rabbits were investigated using electrocorticograms. The extract stimulated metabolic activity of cerebral tissue. Incubation of sliced rabbit brain tissue with the same extract (23 and 46 µg/mL) led to highly significant metabolic changes ($p<0.0005$ compared to control values): glucose uptake increased, while lactate and pyruvate production and the lactate/pyruvate ratio decreased [Hassan Samira 1985].

Male Wistar rats received an extract (standardised to 4% ginsenosides) at a dose of 50 mg/kg p.o. or control (saline) for 12 weeks, with or without exercise training. The muscles of the hindlimb were then extracted after 24 hours of inactivity. The activity of citrate synthase (CS) increased with treadmill exercise but not by the extract. There were no significant changes in lactic dehydrogenase levels, from either the exercise or the extract. The extract did increase the capillary density and the mitochondrial content of the red gastrocnemius muscle. No potentiation was seen when exercise and the extract were combined [Ferrando 1999].

An extract (4% ginsenosides) at doses of 3, 10, 100 or 500 mg/kg or saline (as control) were administered orally for three months to male Wistar rats. The rats were then further split into resting or acute exercise groups (n=8/group). Mitochondrial function was significantly ($p<0.05$) reduced after exercise, this effect was attenuated by 100 mg/kg of the extract, demonstrating a membrane stabilizing capacity. Glutathione status did not show significant changes after exercise or treatment. Lipid peroxidation was significantly ($p<0.05$) higher in all muscles after exercise, but was significantly ($p<0.05$) reduced by about 74% by the extract [Voces 2004].

Treatment of male Wistar rats with an extract (4% ginsenosides) at 100 mg/kg/day p.o. for three months protected their muscles from exercise injuries. The extract significantly ($p<0.05$) reduced the eccentric exercise-induced increases in nitrate concentration in vastus and rectus muscles and carbonyl content in all muscles tested as compared to controls (saline only). The extract also preserved mitochondrial membrane integrity [Cabral de Oliveira 2005].

Male ICR mice received 50, 100, 200 or 400 mg/kg of an extract (not further specified) orally for 1, 3 or 7 days. Administration of 100 mg/kg for 3 or 7 days significantly ($p<0.05$) increased locomotor activity and suppressed the production of plasma corticosterone. This dose increased the time spent in the open arms of the elevated plus maze, and significantly increased rearing frequency ($p<0.05$) as well as endurance time ($p<0.01$-0.05), and decreased falling frequency on the rotating rod after 3 or 7 days. A single dose of 200 mg/kg significantly ($p<0.01$) prolonged endurance time. The same dose for 1 or 3 days significantly ($p<0.05$) increased swimming time in a cold pool, whereas at 100 mg/kg, swimming times were increased after 3 or 7 days of treatment [Choi 2011].

Seven week old ICR mice (n=42) received an extract (19.6% ginsenosides; 1 g/kg/day p.o.) during two weeks of endurance training. Mice were randomized to a training only group (control) and a training with extract group. Glycogen was measured in muscles and liver before, immediately after, and one hour after the exercise. Fat oxidation during the initial 20 min of exercise increased in the treatment group compared to control. The glycogen concentration in white and red gastrocnemius muscle did not differ between the groups immediately after the exercise [Hwang 2014].

The effect of a ginseng extract (4% ginsenosides; 25 mg/kg/day p.o.) on exercise stress was examined in 6-week old male BALB/c mice, with attention on the expression of AMPK, PGC-lα and SIRTI genes, as a coordinated system that controls energy intake. Animals were divided into 4 groups (n=10 each): control group, control extract group, untreated swimming group and extract-treated swimming group. Acute exercise stress (single 60 m swim session) increased the expression of AMPK and PGC-1α, while prolonged exercise stress (daily 60 m swim for 2 weeks) decreased their expression in untreated animals. In contrast, the extract demonstrated no effect on gene expression after acute exercise, but after prolonged exercise AMPK and PGC-1α expression were increased when compared to control mice and untreated swim group mice. Expression of SIRT1 was significantly increased in treated animals after prolonged exercise as compared to the control mice but not the untreated swim group mice [Pannacci 2016].

An ethanolic extract (not further specified) at doses of 5 or 25 mg/kg/day p.o. for four weeks increased grip strength and endurance swimming time, decreased levels of serum lactate, ammonia, creatine kinase and blood urea nitrogen, and economized glucose levels after acute exercise in ICR mice. Glycogen in the gastrocnemius muscle was also increased [Ma 2017].

Crude saponins from 7 different types of ginseng were administered orally to rats at 50 mg/kg b.w. 48 hours and 1 hour before a warm water swimming test. Swimming time until drowning, plasma levels of lactic acid, glucose, insulin and glucagon, and liver glycogen were measured in both resting and drowned animals. The only significant difference ($p<0.05$) was an increased plasma level of glucose in drowned rats that had received saponins from one of the *Panax ginseng* samples tested, when compared to placebo and American ginseng. Plasma glucose levels were lower in most of the resting rats that had received saponins compared to those receiving placebo, but the differences were within normal biological variability [Martinez 1984].

Immunomodulatory and anti-tumour activities

Daily subcutaneous administration to thymectomized rats of an extract (not further specified) corresponding to 25 mg ginseng/kg b.w. for 10 days gave significant protection ($p<0.04$ to $p<0.004$) against intratracheal challenge with alginate-embedded *Pseudomonas aeruginosa* [Song 1997].

BALB/c mice injected with CT-26 mouse colon cancer cells received various doses (0, 75, 150 or 300 mg/kg b.w. p.o.) of an extract (0.519 mg/g ginsenoside Rg1 and 4.028 mg/g ginsenoside Rb1) for 3 weeks. Numbers of pulmonary nodules and plasma MMP-2 and MMP-9 activity were significantly ($p<0.05$) decreased [Seo 2011].

In a mouse model, injection with an ethanolic extract (yield 4.76%; 82.65% ginsenosides; 1 mg/mL) resulted in a significantly

($p<0.01$) higher number of newly formed blood vessels compared to control. After treatment of rat aortic rings with the extract, an approximately 13-fold increase in microvessel sprouting at the cut edge was observed as compared with control (0.23±37 vs. 3.31±.68). The angiogenic activity of the extract at 500 mg/mL was comparable to that induced by VEGF at 10 ng/mL [Kim 2007].

Mice were administered with an extract (20.37% saponins) at 25, 50 or 100 mg/kg p.o. for 15 days, and then infected with a lethal *S. pneumoniae strain*. Survival rate, body weight and colonization were determined. Mice pre-treated with the extract at 100 mg/kg had higher survival rates and body weights as well as lower bacterial number and morbidity than controls. The highest dose decreased cytokine levels including TNF-α ($p<0.05$) and IL-1β ($p=0.051$), NO ($p<0.05$) and neutrophil infiltration 48 h post-infection. In pneumococcal infection, extract pre-treatment downregulated toll-like receptor (TLR) 4 and TNF-α expressions in RAW 264.7 macrophage cells and increased cell survival by activating phosphoinositide 3-kinase (PI3K)/AKT signaling [Nguyen 2015].

In mice, intranasal pretreatment with an extract (not further specified) prevented loss of body weight after infection with respiratory syncytial virus (RSV). The extract improved lung viral clearance and enhanced the production of interferon (IFN-γ) in bronchoalveolar lavage cells upon RSV infection. Analysis of cellular phenotypes in bronchoalveolar lavage fluids showed that the treatment increased the populations of CD8+ T cells and CD11c+ dendritic cells upon RSV infection [Lee JS 2015].

Lactating female mice were intramammarily inoculated with an extract (27% Rg1) at 50 mg/mL or placebo, and then challenged with *Staphylococcus aureus*, while another group was inoculated with *S. aureus* alone. The number of bacteria recovered from mammary glands was lower in the extract treated *S. aureus*-infected mice (group I) compared with placebo-treated *S. aureus*-infected mice (group II) and *S. aureus*-infected mice (group III). The mRNA expression of TLR2, TLR4, IL-1α and TNF-α was influenced by the treatment; the transcript levels for all genes were higher in group I compared with groups II and III. Activation of NF-κB and the number of monocytes-macrophages in mammary gland tissue was significantly ($p<0.05$) increased in group I compared with groups II and III [Silvestrini 2017].

Water soluble ginseng oligosaccharides (1, 12.5 or 25 mg/kg p.o. for 10 days) inhibited tumour growth in H22 ascites inoculated ICR male mice with inhibitory ratios of 36.3%, 58.2% and 41.9% respectively. The relative spleen and thymus weights after 12.5 and 25 mg/kg significantly ($p<0.05$) increased compared with control (saline). All doses significantly ($p<0.01$-0.05) increased TNF-α production, splenocyte proliferation and Con-A-/LPS-induced splenocyte proliferation compared with control. The 12.5 and 25 mg/kg doses significantly ($p<0.01$) enhanced NK cell activity in YAC-1 cell lysis at the E:T cells ratio used compared to control. The two higher doses also significantly ($p<0.01$) improved macrophage phagocytosis and promoted NO generation compared to control [Jiao 2014].

Anti-ulcer effects

Oral administration to rats of 50, 200 or 500 mg/kg b.w. of a 70%-methanol extract dose-dependently inhibited gastric ulceration induced by pyloric ligation, serotonin or endotoxin, but did not inhibit stress-induced ulceration. Serotonin- or endotoxin-induced effects on gastric mucosal tissue blood flow were reduced. Most effects observed after doses of 200 mg/kg or 500 mg/kg were significant ($p<0.05$ or $p<0.01$) [Matsuda 1984].

One week after infection with *Helicobacter pylori*, male mongolian gerbils (5 weeks old) were fed with either a standard diet or a diet containing 200 mg of an aqueous ginseng extract (7% saponins) for 6 weeks. The extract had no effect on the amount of viable *H. pylori* in the stomach. However gastric mucosal lesions showed less inflammatory cell infiltration, hyperplasia and intestinal metaplasia than those of the controls. *H. pylori*-induced chronic inflammation was reduced, neutrophil infiltration in the gastric mucosal lesions was inhibited and increases in myeloperoxidase and lipid peroxide were significantly ($p<0.05$) suppressed. mRNA expression of KC, IL-1α, and iNOS was significantly ($p<0.05$) lower in the treatment group [Bae 2014].

Effect on allergic rhinitis

In a study examining the anti-allergic activity of an extract (not further specified) in a mouse model of allergic rhinitis, female Balb/c mice (n=40) were divided into four groups: saline only (G1); ovalbumin (G2; OVA, 25 μg i.p.); OVA+extract (G3; 2 g/kg p.o.) and OVA+dexamethasone (G4). Serum IgE levels were significantly ($p=0.0006$) lower in G3 than in G2. In the nasal lavage fluid, IL-4 and IL-5 levels were significantly ($p<0.05$) lower in G3 than in G2. Eosinophil count, IL-4, IL-5 and Mucin 5AC-positive cells were significantly ($p<0.05$) lower in G3 and G4 than G2 [Jung 2013].

Antidiabetic effects

Sprague Dawley rats (six weeks old) were divided into four groups: control; streptozotocin (STZ)-induced diabetic group; and STZ-induced groups treated with 100 or 250 mg/kg p.o. of an extract (not further specified) for 28 days. The extract prevented renal hypertrophy in a dose-dependent manner. Elevated plasma and urine parameters induced by STZ were significantly ($p<0.05$-0.001) improved by the extract. The gene and protein expression levels of N-(carboxymethyl) lysine and receptors for advanced glycation end products in treated rats were significantly ($p<0.05$-0.001) reduced compared to the STZ only group. Mitogen-activated protein kinases, the phosphorylated forms of Erk and Jun, as well as the gene and protein expression levels of iNOS and COX-2, were significantly ($p<0.05$-0.001) suppressed with the extract [Quan 2013].

Hepatoprotective effects

Intraperitoneal administration of a single dose of an extract (not further specified) to rats at 50 mg/kg b.w. did not protect the animals against CCl_4-induced hepatotoxicity [Kumazawa 1990].

In rats injected with dexamethasone (0.5 mg and 1.0 mg/day) for 7 days (days 1 to 7), the addition of i.p. administration of an extract (corresponding to 100 mg of root/day on days 5 to 9) significantly ($p<0.05$) reduced the dexamethasone-elevated levels of alanine amino transferase (ALAT) and aspartate amino transferase (ASAT) down to normal [Lin 1995].

Liver fibrosis was induced in mice by CCl_4 injection i.p. three times per week for four weeks. After administration of CCl_4 alone or CCl_4 with an extract (not further specified; 30, 100 or 300 mg/kg p.o. 30 min. prior to each CCl_4 injection) the mice were sacrificed on day 28. Concomitant treatment with the extract at all doses significantly ($p<0.01$) decreased the levels of plasma aminotransferases increased by CCl_4 and the extent of the liver fibrosis was significantly ($p<0.01$) reduced. Treatment with 300 mg/kg distinctly inhibited the scores of collagen deposition in the lateral lobes. The extract prevented the elevation of transforming growth factor β1 and plasminogen activator inhibitor mRNA levels in the liver [Ki 2013].

The effects of an extract (5 mg/g ginsenosides Rb1 and Rg1) on obesity and lipid metabolism were examined in castrated C57BL/6J mice. Mice were divided into three groups (n=8 each)

and given for 8 weeks either a low-fat diet (LFD; group 1), a high fat diet (HFD; group 2) or an HFD supplemented with 5% extract (group 3). Compared with the HFD mice, mice in group 3 showed decreased body weight, adipose tissue mass and adipocyte size without effects on food intake. Serum levels of triglycerides and total cholesterol were lowered in group 3 as compared to group 2. The extract also markedly reduced HFD-induced hepatic lipid accumulation. Concomitantly, the extract decreased mRNA expression of adipogenesis-related genes (SREBP-1C, PPARγ, FAS, SCD1, and ACC1) in visceral adipose tissues compared with the HFD alone [Shin 2018].

Neuroprotective effects
Rodents received a standardised ginseng extract at various oral doses and time intervals prior to and/or following exposure to the Parkinsonism-inducing neurotoxin, 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (mice) or its toxic metabolite, 1-methyl-4-phenylpyridinium (rats). The extract blocked tyrosine hydroxylase-positive cell loss in the substantia nigra and reduced the appearance of locomotor dysfunction [Van Kampen 2003].

An ethanolic extract (not further specified) administered 0 and 90 min after induction of ischaemia, at an optimal i.p. dose of 200 mg/kg, protected CA1 (hippocampal) neurons against transient forebrain ischaemia as demonstrated by the density of neuronal cells in the four-vessel occlusion rat model. The extract also decreased the level of MDA and increased the expression of GPx and SOD [Kim 2009].

In a study investigating the neuroprotective activity of red ginseng extract against kainic acid-induced excitotoxicity, the elevated malondialdehyde levels following injection with kainic acid (30 mg/kg i.p.) were significantly lowered in male mice pre-treated with an extract (4.37% saponins; 30 and 200 mg/kg i.p.) for 10 days ($p<0.01$ and $p<0.001$ respectively) [Han 2012].

An extract (not further specified; 360 mg/kg i.p.) was administered to mice for 2 weeks before occlusion of the middle cerebral artery for 1 hour, followed by reperfusion for 4 and 24 hours (ischaemia/reperfusion I/R). Pretreatment with the extract resulted in a reduction of oxidized hydroethidine signals in ischaemic areas. At 4 and 24 hours after I/R, the number of 8-hydroxyguanosine- and apoptosis signal-regulating kinase 1 (ASK1)-positive cells decreased in the ischaemic penumbra. The extract efficiently attenuated the protein levels of activated ASK1 in the ischaemic penumbra. DNA fragmentation and the infarct volume were reduced by pretreatment 24 hours after I/R. The extract also resulted in better performance in the rotarod test after I/R [Cheon 2013].

Oral administration of an extract (not further specified; 100 mg/kg/day) reduced dopaminergic cell loss, microgliosis and accumulation of α-synuclein aggregates in a rodent model of Parkinson's disease. The extract fully prevented the reduction of locomotor activity and coordination [Van Kampen 2014].

To explore the role of ginseng on neural degeneration, an advanced glycation end product (AGE) model of experimentally inducing Alzheimers was used. AGEs were injected bilaterally into the CA3 region of brains of adult male Sprague-Dawley rats. Subjects were divided into groups including no treatment, and injections of Bovine serum albumin (BSA), AGE (500 µg) and antibodies against receptors for AGE (RAGE - 50 µg). The following day rats began oral treatment for 30 consecutive days with either an aqueous extract (yield 10.4%, 3.31% specified saponins; 0.25, 0.5 or 1 g/kg) or donepezil hydrochloride (2 mg/kg as a positive control) dissolved in saline, or saline alone. The Morris water maze test and step-down type passive avoidance test were performed to evaluate memory and cognitive abilities. The oxidation indexes in the hippocampus were detected. Immunohistochemistry was conducted to visualize the receptors for advanced glycation end products (RAGEs) and nuclear factor-kappa-light-chain-enhancer of activated B cell (NF-B). The AGEs-induced increase in escape latency in the Morris water maze test was shortened by all doses of ginseng from day 2 to 4 ($p<0.01$ and $p<0.05$). Extract treatment at 1 g/kg and 0.5 g/kg also significantly decreased the number of errors ($p<0.01$ and $p<0.05$) and prolonged the latency ($p<0.05$ and $p<0.01$) in the step-down passive avoidance test. The AGEs-induced alterations of MDA, SOD and glutathione levels in the hippocampus were significantly ($p<0.05$ to 0.01) improved by the extract and comparable with the activity of donepezil and anti-RAGE antibody. The increased expressions of RAGE and NF-κB in the cortex and hippocampus in AGEs-induced Alzheimer´s disease were downregulated by the extract in a dose-dependent manner [Tan 2015].

Mice were given either saline, morphine (10 mg/kg i.p.) or both morphine and an extract (not further specified; 250 and 500 mg/kg p.o., 30 min prior to morphine) daily for 7 days. Rats received the morphine with or without 20(S)-ginsenoside Rg3, 20(S)-ginsenoside Rh or the metabolite compound K, with the substances being directly pumped into the right lateral ventricle of the brain for 7 days. Naloxone hydrochloride (5-10 mg/kg i.p.) was injected 6 h after the final morphine injection or cessation of the morphine infusion to induce morphine withdrawal in the mice and rats respectively. The extract at both doses significantly inhibited the number of naloxone-precipitated jumps ($p<0.01$), reduced conditioned place preference score ($p<0.01$) and restored the level of glutathione ($p<0.05$) in mice compared to control. Ginsenosides Rh2, Rg3 and compound K attenuated to varying degrees the morphine-dependent behavioural patterns such as teeth chattering, grooming, wet-dog shake and escape behaviour in rats. Activated N-methyl-D-aspartate acid receptor subunit 1 and extracellular signal-regulated kinase in the frontal cortex of rats and cultured cortical neurons from mice were downregulated by ginsenosides Rh2 and Rg3, and compound K, to varying degrees [Yayeh 2016].

A study examined the effects of an extract (4% ginsenosides) on ethanol-induced depression in mice. For 8 days, mice were administered single oral doses of either water, amitriptyline or various doses (100, 200, 400 and 800 mg/kg) of the extract one hour prior to i.p. injection with water or ethanol. On day 9, in the forced swimming test, 100, 200 and 800 mg/kg of the extract showed antidepressant effects by a significant decrease of immobility time compared to -water-treated controls ($p<0.001$, $p<0.01$, and $p<0.0001$ respectively) while only the highest dose significantly ($p<0.001$) increased swimming time compared to the water control group. In the ethanol-treated mice, compared to those administered ethanol alone, all doses of the extract significantly ($p<0.01$ to $p<0.0001$) reduced immobility time while only the lowest and highest doses significantly ($p<0.0001$) increased swimming time. In ethanol-treated mice, those also receiving the extract demonstrated significant ($p<0.05$ to $p<0.0001$) increases of brain-derived neurotrophic factor in the hippocampus (200, 400 and 800 mg/kg) and prefrontal cortex (200 and 800 mg/kg) compared to ethanol alone [Boonlert 2017].

Mice were treated with an extract (not further specified; 100 and 500 mg/kg/day p.o.) for 12 days following an intrahippocampal β-amyloid (AβO; 10 µM) injection. The extract reduced memory impairment by inhibiting hippocampal cell death caused by AβO. In addition, it restored the reduced synaptophysin and choline acetyltransferase intensity and the lower levels of ionized calcium-binding adaptor molecule 1 in the hippocampus compared with vehicle-treated controls [Choi 2017].

Ginseng total saponins (GTS) were administered i.p. to rats twice a day for 1 week after an induced traumatic brain injury (TBI). GTS (5-80 mg/kg) improved the recovery of neurological functions, including learning and memory, and reduced cell loss in the hippocampal area. The higher doses were more effective than 5 and 10 mg/kg. GTS treatment (20 mg/kg) increased the expression of Neural Growth Factor, Glial cell line-Derived Neurotrophic Factor and Neural Cell Adhesion Molecule, inhibited the expression of Nogo proteins and tenascin-C, and increased the number of BrdU/nestin-positive neural stem cells in the hippocampal area. It also alleviated the secondary brain injury and ameliorated the neurological functions at doses of 5-80 mg/kg [Hu 2014].

Antiviral effect
Female mice (3-4 weeks old) were fed a diet containing 50 mg/kg of an aqueous extract (19.64 mg/g ginsenosides) for up to 80 days prior to intranasal challenge with a lethal dose of H5N1 virus. The survival rate increased depending on the duration of extract administration. Lung tissue from the extract-fed mice showed signs of mild pneumonia with some lymphocyte infiltration while the tissue from virus-challenged controls exhibited severe interstitial pneumonia with heavy lymphocyte infiltration and some mucus in the bronchioles. The induction of TNF-α and IL-4 was similar between controls and extract-treated mice after virus challenge. Induction of IFN-α and IFN-β was significantly ($p<0.05$) higher in the treatment group [Park EH 2014].

Cardiovascular effects
Male Wistar rats (7 weeks old) received a normal or high cholesterol diet with or without oral administration of a 70% methanolic ginseng extract (yield 37-43%) at a dose of 500 mg/kg b.w. Disruption of the membrane localization of multidrug resistance-associated protein (MRP2) was suppressed by the extract in hypercholesterolaemic rats [Kawase 2014]. In an earlier study the same extract decreased levels of LDL and HDL [Kawase 2013].

To evaluate the cardiac effects of an ethanol extract (4% ginsenosides), Wistar-Albino rats were randomly assigned to control group, acute low-dose group (ALD: 100 mg/kg extract for 1 day), subacute low-dose group (SALD: 100 mg/kg extract for 28 days), acute high-dose group (AHD: 500 mg/kg extract for 1 day) and subacute high-dose group (SAHD: 500 mg/kg extract for 28 days). Mean blood pressures were significantly ($p<0.05$) lower in all extract treated groups compared with control. Among various haemodynamic, biochemical, echocardiographic, genetic and immunohistopathologic parameters, troponin I and myoglobin levels were increased in the SALD, AHD and SAHD groups. Mitral E-wave velocity was reduced in all extract groups. Acidophilic cytoplasm and pyknotic nuclei in myocardial fibres were observed in AHD and SAHD groups. Cu/Zn-SOD1 gene expressions were significantly ($p<0.05$) higher in the extract-treated groups whereas caveolin 1 and VEGF-A gene expressions were not changed [Parlakpinar 2019].

Hypertensive rats given a dried aqueous extract (50 g dried cut root /500 mL water) at either 100 or 200 mg/kg b.w. p.o. for 8 weeks showed significantly ($p<0.05$) reduced systolic blood pressure at 4 and 6 weeks compared to control (untreated hypertensive and normotensive rats) [Moon 2019].

Other effects
Adult male Sprague-Dawley rats were administered i.p. methanolic (80%) extracts of wild ginseng (50, 100 or 200 mg/kg; yield 11.6% w/w) or cultivated ginseng (500 mg/kg; yield 20.6% w/w), 30 min. before twice daily morphine injection (40 mg/kg, s.c.) for 5 days. Only the 200 mg/kg dose of extract significantly ($p<0.05$) attenuated the anxiety and depression-like behavioural responses due to morphine withdrawal 72 h after the last morphine injection as compared to the morphine only control group [Lee B 2011].

The behavioural despair model and chronic unpredictable mild stress (CUMS) model were used in mice and rats respectively. Forced swimming test (FST), tail suspension test (TST) and locomotor activity were performed in mice, while the open-field test, food consumption and sucrose preference were assessed in rats. Intragastric administration of compound K, an intestinal metabolite of panaxadiol ginsenosides, at 10 or 30 mg/kg for 14 days significantly shortened the immobility time in FST ($p<0.01$) and TST ($p<0.05$). For CUMS rats, compound K alleviated the depressant-like behaviours, including decreased food consumption, spontaneous locomotor activity and lower sucrose preference, while WAY-100635, a 5-HT1A receptor antagonist, attenuated this effect. In addition, compound K increased the levels of 5-HT, DA and their metabolites in the prefrontal cortex and hippocampus of CUMS rats and reversed overexpression of MAO-B in the prefrontal cortex and hippocampus. Compound K also increased the total glutathione (GSH) and GPx activity in the hippocampus and prefrontal cortex. Expression of brain derived neurotrophic factor and nerve growth factor was increased in treated rats [Song W 2018].

Pharmacological studies in humans

Effects on exercise performance
Twenty top class male athletes received 200 mg of a standardized extract daily for 9 weeks. In a bicycle ergometer exercise lasting 8 minutes, post-treatment values were higher for maximal oxygen absorption and lower for blood lactate and heart rate during exercise compared to pretreatment values. The differences were significant ($p<0.001$) [Forgo 1981a].

In a double-blind study, athletes were given either 200 mg of ginseng extract standardized to 7% ginsenosides (n=10) or 200 mg of ginseng extract standardized to 4% ginsenosides + 400 mg of vitamin E (n=10) or placebo (n=10) daily for 9 weeks. In the same bicycle ergometer test, significant differences were observed in favour of both ginseng preparations compared to placebo with respect to heart rate ($p<0.05$), blood lactate ($p<0.01$) and maximal oxygen absorption ($p<0.01$) after exercise. Differences between the two ginseng preparations were not significant. Levels of testosterone and luteinising hormone in plasma and of free cortisol in urine were unchanged after all treatments [Forgo 1981a, 1983].

A double-blind, placebo-controlled study involving 28 trained male athletes examined the persistence of effects of a 9-week treatment with 200 mg of ginseng extract (4% ginsenosides) or placebo beyond the treatment period. Compared to placebo, the extract produced significant improvements in maximal oxygen uptake during exercise ($p<0.01$), heart rate at maximal exercise ($p<0.001$), forced expiratory volume ($p<0.01$), forced vital lung capacity ($p<0.05$) and visual reaction time ($p<0.01$). These positive effects lasted for at least 3 weeks after treatment [Forgo 1985].

In a study of the blood oxygenation status of 8 male and 2 female middle-aged subjects (average age 50 years), a significant ($p<0.05$) increase in resting arterial pO_2 was observed after 4 weeks of daily oral treatment with 200 mg of a standardized extract; the resting arterial pO_2 increased by 4.5 mm Hg. In synergy with oxygen treatment the increase was 10.1 mm Hg. Venous pO_2 decreased (4.3 mm Hg) [Von Ardenne 1987].

In a double-blind, placebo-controlled, crossover study, 43 top triathletes received either 200 mg of a standardized extract or placebo daily for periods of 10 weeks. Significant differences ($p<0.05$) in various endurance parameters were seen only after the second treatment phase [Van Schepdael 1993].

The effects of a standardized extract on psychological mood states and perceptual response to submaximal and maximal exercise stress were evaluated in 19 young adult females who received either 200 mg of the extract (n=10) or placebo (n=9) daily. The results did not show an enhancement in psychological function characteristics either at rest or during exercise stress [Smith 1995].

The effects of a standardized extract (300 mg/day) were compared to placebo in 41 healthy male students (aged 19-26 years), either untrained or undergoing regular bicycle ergometer training, in an 8-week randomized, double-blind study. Administration of the extract produced significant ($p<0.05$) effects comparable to training on VO2 max and various aerobic fitness parameters, as well as on anaerobic power and leg muscle strength, when compared to the untrained placebo group. However, no clear synergistic effect on these fitness variables was noted when administration of the extract was combined with the exercise training [Cherdrungsi 1995].

In a double-blind, placebo-controlled, crossover study in 8 healthy volunteers (mean age 25 years) regularly practising physical activities, 30 days of oral treatment with 400 mg of a standardized extract did not improve performance during supramaximal exercise, nor did it influence blood lactate or blood testosterone levels [Collomp 1996].

In a randomized, double-blind, placebo-controlled study, healthy female volunteers received 200 mg of a standardised extract (equivalent to 1000 mg ginseng root; n=10) or placebo (n=9) daily for 8 weeks. Assessment before and after treatment with a standard, graded maximal exercise protocol found the extract had no effect on maximal work performance or on resting, exercise and recovery oxygen uptake, respiratory exchange ratio, minute ventilation, heart rate or blood lactate [Engels 1996].

In another randomized, double-blind, placebo-controlled study, healthy male volunteers received either a standardised extract at 200 mg (equivalent to 1000 mg ginseng root; n=11) or 400 mg (equivalent to 2000 mg ginseng root; n=10) or placebo (n=10), daily for 8 weeks. Assessment before and after treatment with a standard, graded maximal exercise protocol found the extract had no effect on oxygen consumption, respiratory exchange ratio, minute ventilation, blood lactic acid concentration, heart rate or perceived exertion at either dose [Engels 1997].

In a randomized, double-blind, placebo-controlled study, 24 healthy, active women were given either a ginseng extract (4% ginsenosides; 400 mg/day; n=12) or placebo (n=12) for 8 weeks. Before and at the end of the trial, each participant performed an all-out-effort, 30-second leg cycle ergometry test (Wingate protocol) followed by a controlled recovery under constant laboratory conditions. Analysis of variance using pre-test to post-test change scores revealed no significant difference between the ginseng and placebo groups for peak anaerobic power output, mean anaerobic power output, rate of fatigue and immediate post-exercise recovery heart rates [Engels 2001].

In a randomized, double-blind study, 38 active healthy adults (26-28 years) took either a standardized extract (400 mg/day, equivalent to 2 g root) or placebo for 8 weeks. Pre-treatment, the secretory immunoglobulin A (SigA) secretion rate, SigA:protein ratio and saliva flow rate were significantly ($p<0.05$) lower after the maximal exercise test (consecutive Wingate tests with recovery periods) than beforehand. Both peak and mean mechanical power output significantly ($p<0.05$) declined across consecutive Wingate tests. There were no significant differences between the extract and placebo groups in any of the post-treatment scores, before or after the exercise test, including salivary parameters, exercise performance and heart rate recovery. The study concluded that the extract did not improve physical performance and heart rate recovery of individuals undergoing repeated bouts of exhausting exercise [Engels 2003].

The effect of an extract (8% ginsenosides; 1200 mg/day), in addition to a strength training programme (60 minutes per week), was examined in a randomized, placebo-controlled, double-blind study involving 24 men and 46 women (64.7 ±5.5 years). Subjects were assigned to one of 4 groups and treated for 12 weeks with either: the extract alone, strength training alone, extract & strength training or placebo. The study revealed significant ($p<0.01$) reductions in heart rate and body fat percentage in the extract-treated groups compared to placebo and strength values were also higher after 12 weeks of treatment [Schott 2006].

Sixty physically active men (aged 17-22 years) were randomized to receive either ginseng (3 g/day of powdered root; n=30) or placebo (n=30) for 8 weeks in a double-blind study. Blood lactic acid levels for determination of lactate threshold (LT) were measured during an incremental cycle ergometer test. LT exercise performance and heart rate (HR) responses to exercise were determined at baseline and after 8 weeks of treatment. Substrate oxidation rates during steady state exercise were assessed upon study completion. There were no significant differences between the extract and placebo groups in terms of LT before and after treatment, exercise heart rate, total exercise time, peak power output and oxidation rates of fat or carbohydrate [Kulaputana 2007].

Eighteen male students (aged 19-22 years) were randomly assigned to receive either an extract (n=9) or placebo (n=9). All performed a high-intensity uphill treadmill running task. The extract group received 20 g of Korean red ginseng extract (not further specified, mixed with 200 mL of water) three times a day for 7 days prior to the test and for three days after the test, while the placebo group ingested 200 mL of water infused with Agastachis Herba (10 g/500 ml water) using the same schedule. The exercise induced a significant elevation in plasma creatine kinase (CK) in both groups. However, the CK level was significantly ($p<0.05$) lower in the extract group compared to placebo 72 h post-exercise, and IL-6 levels were significantly ($p<0.05$) decreased at the 2 h and 3 h recovery periods compared to placebo. Plasma glucose and insulin levels were significantly ($p<0.05$) reduced following the extract compared to placebo, at 60 min and 90 min post-exercise respectively [Jung HL 2011].

In a randomised, double-blind, placebo-controlled, crossover study, healthy, active women (38.7±7.8 years; n=10) and men (41.2±9.7 years; n=9) participated in three 14 day treatment cycles consisting of supplementation with a high dose (960 mg/day) of a ginseng preparation (compound K), a low dose (160 mg/day) of the ginseng and placebo. After 14 days of supplementation participants performed an acute resistance exercise trial (5 sets of 12 repetitions of the leg press at 70% of one-repetition-maximum). Ratings of perceived exertion were assessed after each set. Muscle pain/soreness was assessed before exercise and 24 hours post exercise. Psychomotor performance and peak power were measured before exercise, immediately post exercise and 24 hours after exercise. Each treatment cycle was separated by a minimum one-week washout period. The high

dose significantly reduced perceived exertion during exercise compared with the low dose (p=0.004) and placebo (p=0.038). The high dose (p=0.014) and low dose (p=0.011) showed significantly lower muscle soreness at 24 hours post exercise compared to placebo. Analysis of peak power demonstrated the presence of responders (n=13) and non-responders (n=6). Responders showed a significantly (p<0.05) greater effect of the high dose on maintenance of neuromuscular function (peak power) when compared to low dose and placebo. Blood was taken at rest and immediately, 30 min, 60 min and 24 h after exercise. Cortisol, superoxide dismutase, total glutathione, nonspecific antioxidant activity, total antioxidant power and creatine kinase were measured. Ginseng attenuated exercise stress-induced elevated levels of circulating cortisol for up to an hour after exercise at both doses in women and the highest dose in men. Twenty-four hours after exercise, the high dose significantly (p<0.05) reduced muscle damage (reduction in creatinine kinase) compared to the placebo and low dose. There was a significant (p<0.05) increase in various enzymatic and antioxidant activities at the higher dose as compared to placebo and the low dose. The ginseng demonstrated a dose dependent inhibitory effect on the hypothalamus-pituitary-adrenal axis responses to physical stress in humans [Caldwell 2018; Flanagan 2018].

In a 12-week randomized, double-blind, placebo-controlled trial, a ginsenoside complex (10% protopanaxadiol ginsenosides: Rg3, Rg5, Rk1) was evaluated in sedentary healthy adults (n=117: 85 women, 32 men, aged: 22-60) assigned into one of three groups: low-dose ginsenoside (100 mg/d, n=39), high-dose ginsenoside (500 mg/d, n=39) or placebo (n=39). All participants underwent a supervised 12-week aerobic and resistance exercise training course. The effects on physical performance were assessed by maximal oxygen consumption (VO_2 max), anaerobic threshold (AT), lactic acid and muscle strength of the dominant knee at baseline, at every visit and after the training programme. VO_2 max of the high- and low-dose groups significantly (p<0.001 and p=0.005) improved during exercise compared to baseline. There were no definite changes in AT and lactic acid levels over time. After exercise significant differences were seen in the VO_2 max (p=0.029) and AT (p=0.038) between the high-dose ginsenoside and placebo groups. No significant difference in VO_2 max between the low-dose ginsenoside and placebo groups was observed as well as no differences in muscular strength between the three groups [Lee 2018].

Effects on cognition, mental performance and the stress response
