In a prospective, open, multicentre study, 361 patients (1-94 years) with acute sinusitis or acute exacerbation of chronic sinusitis were treated with the liquid extract. Adults/children (< 12 years) received 1.5/1 mL every hour up to 12 times daily on the first 2 days and thereafter 1.5/1 mL three times daily for 28 days. Patients with chronic sinusitis received prophylactic treatment for a further 8 weeks at 1.5/1 mL two times daily. The mean SSS of all patients decreased from 15.2±4.6 points at baseline to 2.4±3.2 points at day 28. Within 4 weeks 82.3% of the patients showed a complete remission or a clear improvement in symptoms [Schapowal 2007].

Common cold
In a randomized, double-blind, placebo-controlled, multicentre trial, 103 patients (18 – 55 years) with common cold (at least 2 major and 1 minor, or 1 major and 3 minor cold symptoms) received the liquid extract (1.5 mL three times daily) or placebo for 10 days. The decrease of the mean SSID (sum of symptom intensity differences) of the cold intensity score (CIS) from baseline to day 5 was significantly improved for the verum group ($p<0.0001$) compared to placebo (14.6±5.3 versus 7.6±7.5). The mean CIS decreased by 10.4±3.0 points in the verum group versus 5.6±4.3 points in the placebo group. After 10 days 78.8% of the patients in the verum group were free of symptoms (CIS = 0) versus 31.4% in the placebo group ($p<0.0001$) [Lizogub 2007].

Upper respiratory tract infections
A multicentre, post marketing surveillance study was carried out in 166 patients (1-19 years) with acute and chronic ear, nose, throat and respiratory tract infections. They were treated for up to 7 days (88 patients), 8 to 14 days (60 patients) and more than 14 days (16 patients) with the liquid extract at a dosage according to their age: 1-6 years 0.75–1.5 mL daily, 6-12 years 1.5–3 mL daily and >12 years 3–4.5 mL daily. The assessment of the subjective symptoms was performed by both physicians and patients/parents on a 4-point rating scale. The response rate (remission and improvement) was between 70% and 90% for the different symptoms such as coughing, fever, expectoration and pain [Heil 1994].

In a study investigating the prevention of asthma attacks during upper respiratory tract viral infections, 61 children received the liquid extract at a daily dosage according to their age (1-5 years: 3x0.5 mL, 6-12 years: 3x1 mL and >12 years: 3x1.5 mL) or placebo for 5 days. After assessment of the symptoms, significant improvement ($p<0.05$) of cough frequency and nasal congestion was observed in the verum group; for fever and muscles aches there was no significant difference. The frequency of asthma attack was also significantly ($p<0.05$) reduced in the verum group [Tahan 2013].

In a prospective, open, multicentre study, 641 patients (10-60 years) were treated with the liquid extract at an age-dependant dosage for a maximum of 14 days. Improvement of symptoms was observed after 7 days (n=240) and 14 days (n=305). In 88.9% efficacy was assessed as "very good" or "good" [König 1995 in Brendler 2009].

Pharmacokinetic properties
No data available.

Preclinical safety data
No effect on thromboplastin time (TPT), partial TPT or thrombin time (TT) was observed in rats after oral administration of the liquid extract (up to 500 mg/kg b.w, for 2 weeks), while treatment with warfarin (0.05 mg/kg b.w.) resulted in significant changes in TPT and partial TPT. The anticoagulant activity of warfarin was not influenced when warfarin (0.05 mg/kg b.w.) and the extract (500 mg/kg b.w.) were given concomitantly [Koch 2007].

The coumarins found in pelargonium root do not possess the structure required for anticoagulant activity [Arora 1963, Williamson 2009].

Toxicological studies in rats and dogs revealed a no observed effect level of more than 750 mg liquid extract/kg b.w. At a dose of 3 g/kg no signs of hepatotoxicity were found after morphological and histopathological examination. Incubation of human hepatocytes and hepatoma cells with 50 µg/mL extract confirmed the non-hepatoxicity. Based on theoretical considerations the metabolism of 7-hydroxycoumarins (present in pelargonium root) by 3,4-epoxidation leading to formation of hepatotoxic metabolites is very unlikely [Loew 2008].

The effects of oral administration to rats of an aqueous extract (approx.16:1), at 100, 200 and 400 mg/kg b.w. for 21 days, on haematological and biochemical parameters, and on the organ body-weight ratio were investigated. Red blood cell count, haemoglobin, platelets, lymphocytes, total proteins, globulin and sodium levels were significantly increased, while the levels of alkaline phosphatase, chloride and uric acid were significantly reduced ($p<0.05$). No deaths or clinical signs were observed [Adewusi 2009].

Clinical safety data
The available data from clinical trials do not show an elevated risk of serious adverse events. However, gastrointestinal complaints such as nausea, vomiting, diarrhoea and heartburn, and allergic skin reactions with pruritus and urticaria, have been reported [Agbabiaka 2008, Timmer 2013, Brendler 2009, Brown 2009]. The following are adverse reports from clinical papers cited above.

Fifty one patients from the verum group (n=99) experienced 79 adverse events, compared to 40 patients with 46 adverse events in the placebo group (n=101). Most were gastrointestinal complaints and none were classified as serious. The incidence of suspected adverse reactions (events/day of exposure) was 0.001 [Matthys 2013].

Only 3 adverse events were observed in 2 of 111 patients in the verum group and all were classified as non-serious with no causal relationship with the medication [Kamin 2012].

A total of 59 adverse events were observed in 55 of 200 patients, for 8 events a causal relationship with the medication could not be excluded. None of the adverse events was classified as serious and most of the events were gastrointestinal complaints (17 patients in the verum group and 7 in the placebo group). The mean values of clinical laboratory parameters, such as different transferase enzymes, showed no group differences [Kamin 2010a].

At least one adverse event occurred in 47 of 217 patients (23 verum, 24 placebo), in 25 of 124 patients (15 verum, 10 placebo) and in 36 of 468 patients (20 verum, 16 placebo). All events were assessed as non-serious [Matthys 2007c, Chuchalin 2005, Matthys 2003].

Eighteen adverse events were observed in 16 of 205 patients,

all were assessed as non-serious [Matthys 2007a].

A total of 28 adverse events occurred in 26 of 2099 patients, of which 14 were in children (13/420 patients) and 4 in infants (3/78 patients). Most of them were coded as gastrointestinal disorders. For 9 adverse events a causal relationship to the medication could not be excluded, but was assessed as unlikely in 8 cases. In one child there was a hypersensitivity reaction possibly related to the medication [Matthys 2007b].

Only 8 of 742 patients (<12 years) experienced adverse events which were probably related to the medication. In 2 patients exanthema occurred and in one diarrhoea; in 2 patients psychomotor restlessness was reported [Haidvogl 1996].

In 152 of 806 patients 155 adverse events occurred, most of them classified as gastrointestinal disorders. No serious events were reported [Kamin 2010b, Matthys 2010a].

Adverse events occurred in 15 of 143 patients (1 verum; 14 placebo) and were not related to the medication [Bereznoy 2003].

At least one adverse event occurred in 8 of 103 patients. All events were assessed as non-serious. In 4 cases a causal relationship with the drug could not be excluded (3 gastrointestinal complaints and 1 allergic skin reaction) [Bachert 2009].

For 21 of 67 adverse events, in 17 of 361 patients, a causal relationship with the medication could not be excluded. Most of the events were gastrointestinal complaints [Schapowal 2007].

Adverse events occurred in 3 of 103 patients (2 verum; 1 placebo) and all were assessed as non-serious [Lizogub 2007].

In a study with 166 patients neither interactions nor undesirable effects were observed [Heil 1994].

In the period from 2002 to 2006, the Uppsala Monitoring Centre received 34 case reports of hypersensitivity reactions suspected to be associated with the use of pelargonium. In 14 of these reports, the description and timing of the event was indicative of an acute Coombs and Gell type I hypersensitivity reaction. Two of the patients needed treatment for circulatory failure or anaphylactic shock [de Boer 2007].

In two studies, a total of 28 spontaneous reports of primarily assumed hepatotoxicity associated with the use of pelargonium were assessed using the liver specific scale of the Council for International Organisations of Medical Sciences. None of the cases of liver disease generated a positive signal of safety concern since causality for pelargonium could not be established [Teschke 2012a and 2012b].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

PLANTAGINIS LANCEOLATAE FOLIUM/HERBA 2013

Ribwort Plantain Leaf/Herb

DEFINITION

Ribwort plantain leaf consists of whole or fragmented dried leaf and scape of *Plantago lanceolata* L.*s.l.* It contains not less than 1.5 per cent of total *ortho*-dihydroxycinnamic acid derivatives, expressed as acteoside ($C_{29}H_{36}O_{15}$; M_r 624.6) (dried drug). Ribwort plantain leaf complies with the monograph of the European Pharmacopoeia [Ribwort Plantain].

Ribwort plantain herb consists of the dried flowering aerial parts of *Plantago lanceolata* L. The material complies with the Deutsches Arzneibuch [Spitzwegerichkraut 1996].

Fresh material may also be used, provided that when dried it complies with the monograph of the respective pharmacopoeia.

CONSTITUENTS

The characteristic constituents are complex mucilage polysaccharides (6.5%): consisting of galactose (44%), arabinose (32%), glucose (9%), mannose (4%), rhamnose (7%), galacturonic acid, glucuronic acid, fucose and xylose [Bräutigam 1985a], iridoid glycosides principally aucubin (1-3%) and catalpol (1%), dihydroxycinnamic acid derivatives such as acteoside (3.5%), plantamajoside (1%), isoacteoside and lavandulifolioside and further caffeoyl derivatives. Further constituents are flavonoids (glycosides of apigenin and luteolin), saponins and tannins [Blaschek 2007; Bräutigam 1985a; Bräutigam 1985b; Darrow 1997; Handjieva 1991; Háznagy 1976; Kardosova 1992; Marchesan 1998a; Murai 1995; Paper 1999].

CLINICAL PARTICULARS

Therapeutic indications

Catarrh of the respiratory tract [Blaschek 2007; Kraft 1996; Kraft 1997; Kraft 1998; Schilcher 2007; Willuhn 2002].

Temporary, mild inflammatory conditions of the oral and pharyngeal mucosa [Blaschek 2007; Schilcher 2007; Willuhn 2002]. Insects bites and wound healing [Marchesan 1998a,b; Schilcher 2007].

Efficacy in these latter indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adults: average daily dose, 3-6 g of the drug or equivalent preparations [Kraft 1996; Kraft 1997; Willuhn 2002].
Elderly: dose as for adults.
Children, average daily dose: *>1-4 years of age*, 1-2 g; *4-10 years*, 2-4 g; *10-16 years*, 3-6 g [Kraft 1998; Dorsch 2002].

Fresh crushed leaves to be applied on insect bites [Schilcher 2007].

Method of administration
For oral and topical administration.

Duration of administration
If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.

E/S/C/O/P MONOGRAPHS

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None known.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Anti-inflammatory activity
Four different freeze-dried extracts (ethanol 28%) from ribwort plantain herb were evaluated for anti-inflammatory activity in a modified hen's egg chorioallantoic membrane (HET-CAM) test using sodium dodecyl sulphate as the membrane irritant. At concentrations of 500 µg/pellet all the extracts inhibited the formation of blood vessels around the granuloma and the total blood vessel net appeared normal. Two extracts inhibited membrane irritation by 100%, the other two by 67 and 93% respectively. The activity of the extracts was comparable to that of hydrocortisone, phenylbutazone and diclofenac, each at 50 µg/pellet [Marchesan 1998a; Marchesan 1998b].

Acteoside and plantamajoside inhibited 5-lipoxygenase with IC_{50} values of 13.6 and 3.75×10^{-7} M respectively [Ravn 1990].

In human polymorphonuclear leukocytes acteoside inhibited the production of 5-HETE with an IC_{50} of 4.85 µM and leukotriene B_4 with an IC_{50} of 2.93 µM. In peritoneal leukocytes from mice, 5-HETE production was inhibited with an IC_{50} of 5.27 µM [Kimura 1987].

An ethanolic extract of the whole plant inhibited nitric oxide (NO) production dose-dependently in the murine macrophage cell line J774a.1. Moreover, the extract was shown to have NO-scavenging activity and an inhibitory effect on nitric oxide synthase gene expression (Vigo 2005).

Antibacterial and antiviral activity
Expressed juice and aqueous, methanolic and ethanolic extracts of ribwort plantain leaf have shown inhibitory activity against various microorganisms such as *Bacillus subtilis*, *B. cereus*, *Klebsiella pneumoniae*, *Micrococcus flavus*, *Mycobacterium phlei*, *Pseudomonas aeruginosa*, *Proteus vulgare*, *Staphylococcus aureus*, *Streptococcus aureus*, *S.* β-*haemolyticus* and *S. pyocyaneus*, and against several strains of *Salmonella* and *Shigella* in the plate diffusion test [Blaschek 2007; Bräutigam 1985c; Elich 1966; Felklová 1958; Hänsel 1966; Tarle 1981].

Aucubigenin, the aglycone of aucubin, has been shown to be mainly responsible for antibacterial activity of the drug and extracts [Háznagy 1976; Elich 1966; Hänsel 1966; Elich 1962; Háznagy 1970]. Extracts without aucubin exerted no antibacterial effects [Elich 1962].

Aucubin preincubated with β-glucosidase suppressed hepatitis B virus DNA replication in HepG2 cell cultures in a dose-dependent manner [Chang 1997].

Spasmolytic activity
A fluid extract (1:1) from ribwort plantain herb inhibited contractions of isolated guinea pig ileum induced by acetylcholine, histamine, K^+ and Ba^{2+} by 50% at 10 mg/ml and 100% at higher concentrations. The effects were comparable to those of atropine, diphenhydramine and papaverine. With preparations of isolated guinea pig trachea, only Ba^{2+}-induced contractions were inhibited, by 30% at 10 mg/ml [Fleer 1997].

Acteoside inhibited histamine- and bradykinin-induced contractions of isolated guinea-pig ileum with pA values of 6.31 and 6.51 respectively [Schapoval 1998].

An extract (20% ethanol) from ribwort plantain (not specified) and isolated constituents were investigated for antispasmodic activity in the isolated guinea-pig ileum and trachea models. Ribwort plantain extract showed antispasmodic activity in a dose-dependent manner in both the ileum and the trachea. Luteolin, acteoside and plantamajoside, but not catalpol, isoacteoside, lavandulifolioside nor aucubin, inhibited agonist-induced contractions in the ileum. In addition, luteolin and acteoside also inhibited agonist-induced contractions in the trachea (Fleer 2007).

Immunostimulant activity
At a concentration of 0.0002% the polysaccharides of ribwort plantain leaf increased phagocytosis of granulocytes by 20.5%. Chemiluminescence was increased by 36% at a concentration of 0.001% [Bräutigam 1985c].

Polysaccharides (consisting of galactose, arabinose and rhamnose) isolated from the leaves showed immunomodulatory activity in the mitogenic and comitogenic rat thymocyte tests. The activity was dose-dependent and reached a maximum stimulatory response at a concentration of 1.0 mg/ml (Ebringerová 2003).

Antioxidant activity
A methanolic extract from ribwort plantain (not specified) was shown to have antioxidant activity in the DPPH radical scavenging test and the inhibition of Fe^{2+}/ascorbate-induced lipid peroxidation on bovine brain liposomes (Galvez 2005).

Other effects
The mucociliary transport velocity in isolated ciliated epithelium from the frog oesophagus was not influenced by application of 200 µl of an infusion from ribwort plantain herb (4.6 g per 100 ml of water) [Müller-Limmroth 1980].

Polysaccharides from ribwort plantain were investigated for bioadhesion to epithelial tissues in a novel ex vivo model using porcine buccal membranes. Adhesion to epithelial tissues was measured as a decrease in polysaccharide concentration. The decrease was approximately 5 and 20 % after 1 and 3 hours of treatment respectively (Schmidgall 2000).

In vivo experiments

Anti-inflammatory effects
Oral pre-treatment of rats with a dry 80%-ethanolic extract

from ribwort plantain leaf at 100 mg/kg body weight inhibited carrageenan-induced paw oedema by 11% (not significant) compared to 45% inhibition by indomethacin at 5 mg/kg [Mascolo 1987].

A freeze-dried extract from ribwort plantain leaf, administered intraperitoneally to rats, reduced the inflammatory effect and leukocyte infiltration induced by simultaneous subplantar injection of carrageenan and prostaglandin E1 [Shipochliev 1981].

Aucubin administered orally at 100 mg/kg body weight inhibited carrageenan-induced mouse paw oedema by 33.0% after 3 hours ($p<0.01$), compared to 44% inhibition by oral indomethacin at 7 mg/kg ($p<0.01$). In the 12-*O*-tetradecanoylphorbol acetate (TPA)-induced mouse ear oedema test, aucubin applied topically at 1 mg/ear inhibited oedema by 80% ($p<0.01$), compared to 87% inhibition by indomethacin at 0.5 mg/ear ($p<0.01$) [Recio 1994].

Oral pretreatment of rats with acteoside at 150 mg/kg body weight significantly inhibited carrageenan-induced rat paw oedema by 96 and 94% after 2 and 4 hours respectively compared to vehicle controls; oral indomethacin at 10 mg/kg caused 25 and 40% inhibition after 2 and 4 hours respectively [Schapoval 1998].

Topical pretreatment with acteoside or plantamajoside at 3 mg/ear inhibited arachidonic acid-induced mouse ear oedema by 14% ($p<0.05$) and 25% ($p<0.01$) respectively, compared to 38% inhibition by phenidone at 0.1 mg/ear ($p<0.01$) [Murai 1995].

Following intraperitoneal administration of acteoside in the mouse dextran sulphate sodium-induced colitis model, significant improvements in histological scores of colonic tissues compared to controls were observed ($p < 0.02$). A decrease in production of immunoregulatory and proinflammatory cytokines was also observed (Hausmann 2007).

Antiulcerogenic effects
Administration of an aqueous extract of ribwort plantain leaf to mice (200 or 400 mg/kg p.o.) and rats (140 or 280 mg/kg intraduodenally) demonstrated activity in a variety of ulcer models, with the higher doses providing better protection than lower doses. The higher dose significantly ($p<0.001$) reduced the ulcer index compared with control in a mouse model of acetic acid-induced ulcer, and had slightly greater activity than ranitidine (70 mg/kg) and pure mucilage (172 mg/kg). In a mouse model of indomethacin-induced ulcer, the higher dose significantly ($p<0.001$) reduced the ulcer score compared with control and had a slightly greater effect than misoprostol (280 µg/kg). In a mouse model of cysteamine HCl-induced ulcer, the higher dose significantly ($p<0.001$) reduced the ulcerated area compared with control, but to a slightly lesser degree than ranitidine (70 mg/kg). In a rat model of pylorus ligation-induced ulcer, the higher dose significantly ($p<0.01$) reduced ulcer score compared with control and conferred better protection than ranitidine (50 mg/kg; $p<0.05$). In this model both doses of the leaf extract also significantly ($p<0.001$) increased mucin levels compared with control (Melese 2011).

Immunostimulant effects
Interferon production in mice increased by 15-fold and 3-fold respectively 24 and 48 hours after intravenous administration of 0.2 ml of a decoction from ribwort plantain leaf (2 g in 100 ml of water) [Plachcinska 1984].

An aqueous extract from ribwort plantain leaf increased SRBC-antibody production and the liberation of angiogenesis factor in mice [Strzelecka 1995].

Analgesic activity
Three phenylethanoid-based fractions of a methanolic extract from ribwort plantain: phenylethanoid-flavonoidic fraction (49.5% acteoside, 11.6% luteolin-7-glucoside, free of iridoids); phenylethanoid fraction (46.6% acteoside); phenylethanoid-iridoidic fraction (48.8% acteoside, 4.9% catalpol, 7.8% aucubin, free of flavonoids) were investigated in the hot-plate test and the acetic acid-induced writhing test in mice (2 testing groups and one blank control group, 10 mice for every experiment). Following intraperitoneal administration all 3 fractions showed analgesic activity. The phenylethanoid fraction had a more rapid and prolonged effect compared to the phenylethanoid-flavonoidic and phenylethanoid-iridoidic fractions (Armatu 2007).

Anthelmintic activity
Dry extracts (90% ethanolic 9:1 and aqueous 14:1) from the leaves were investigated for anthelmintic activity against pinworm parasites in male swiss albino mice (groups of 6 mice). The extracts were administered orally at a dose of 100 mg/kg body weight. The ethanolic extract demonstrated significant activity against the pinworm parasites: 41.6 % efficacy in eliminating *Syphacia obvelata* ($p<0.05$) and 44.5 % efficacy in eliminating *Aspiculuris tetraptera* ($p<0.05$). The aqueous extract also showed activity but this was not significant: 30.7 % efficacy in eliminating *Syphacia obvelata* and 35.9 % efficacy in eliminating *Aspiculuris tetraptera* (Kozan 2006).

Other effects
In a model of diet-induced obesity in C57BL/6J mice, addition of 10 % ribwort plantain leaf powder to a high fat diet for 28 days led to a significant reduction in body weight ($p<0.05$) and visceral fat ($p<0.01$) despite not affecting food intake. Mice consuming the ribwort plantain also exhibited significantly lower ($p<0.05$) serum free-fatty acids and glucose levels than control mice (Yoshida 2012).

Pharmacological studies in humans
No data available.

Clinical studies
In an open study 593 patients with acute respiratory complaints such as acute bronchitis and post-infectious dry cough were treated, for 10 days on average, with a mean daily dose of 31.3 ml of a syrup, equivalent to about 6.3 g of ribwort plantain herb (100 ml of the syrup contained 20 g of fluid extract 1:1 of the herb). Symptoms declined significantly ($p<0.001$), the overall symptom score declining by about 65%. Compared to initial values, the subjective score reductions were: cough frequency, 65.5%; cough intensity, 66.9%; cough-related chest pain, 79.9%; dry cough, 68.5%; dyspnoea, 69.6%; rales, 69.9%; and obstructive "whistling", 74.6%. Expectoration improved by 73.3% and purulent sputum decreased by 66.4%. Global efficacy evaluated by the physicians was excellent in 25.9% of patients, good in 61.8%, moderate in 7.8% and minimal in 2% [Kraft 1996; Kraft 1997].

Similar results were reported in a subgroup of the 91 patients under 18 years of age (58 of them under 13 years) in the above study. In this subgroup the mean daily dose was 22.4 ml of the syrup, equivalent to about 4.5 g of ribwort plantain herb, and the mean duration of treatment was 8.8 days. The overall symptom score declined by about 58.3%. The physicians evaluated global efficacy as excellent in 22%, good in 63.7%, moderate in 9.9% and minimal in 1.1% of patients [Kraft 1998].

Pharmacokinetic properties
No data available.

Preclinical safety data
An aqueous extract of *Plantago lanceolata* leaf did not produce acute toxicity in rodents (species undefined) at a dose of 2000 mg/kg; the authors state that the LD_{50} of the extract was above 2000 mg/kg (Melese 2011).

No repeated-dose or reproductive toxicity data are available.

A tincture of ribwort plantain herb (1:5, 70 % ethanol) showed no mutagenicity in the Ames Test using *Salmonella typhimurium* strains TA98 and TA100, with or without metabolic activation [Schimmer 1994].

In a somatic segregation assay in the diploid strain *Aspergillus nidulans* D-30 no genotoxic effects (neither chromosomal damage caused by aneuploidy and clastogenic effects nor mitotic crossover) were detected after plate incorporation of 4.76 mg/ml of a fluid extract of ribwort plantain leaf [Ramos Ruiz 1996].

Clinical safety data
In the open study involving 593 patients there were only 7 minor adverse events, mainly diarrhoea (n = 5) [Kraft 1996; Kraft 1997; Kraft 1998].

Two cases of phytophotodermatitis have been reported following the consumption of ribwort plantain herb and exposure to sunlight. A 42-year-old woman and her 2-year-old daughter presented to an outpatient clinic with a blistered rash on sun exposed areas that had appeared 4 to 5 hours after a 2 hour exposure to sunlight, 24 hours after consumption of an undefined amount of the plant (identity confirmed by the Department of Medical Biology, Yüzüncü Yil University, Turkey)[Ozkol 2012].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

PLANTAGINIS OVATAE SEMEN 2020

Ispaghula Seed

DEFINITION

Ispaghula seed consists of the dried ripe seeds of *Plantago ovata* Forssk. (*Plantago ispaghula* Roxb.).

The material complies with the monograph of the European Pharmacopoeia [Plantaginis ovatae semen].

CONSTITUENTS

About 80% [Leng-Peschlow 1991] of total dietary fibre when determined by the AOAC method [Prosky 1985], consisting predominantly of insoluble fibre (ratio of soluble to insoluble fibre, 47:53) [Leng-Peschlow 1991]. Soluble fibre occurs in the epidermis as a mucilage polysaccharide consisting mainly of a highly-branched arabinoxylan with a xylan backbone and branches of arabinose, xylose and 2-*O*-(galactosyluronic acid)-rhamnose residues [Kennedy 1979; Sandhu 1981].

The seeds also contain proteins, fixed oil, sterols and the trisaccharide planteose [Heckers 1984; Sharma 1986; Wichtl 1999].

CLINICAL PARTICULARS

Therapeutic indications

Treatment of occasional constipation [Kay 1978; Sölter 1983; Marlett 1987; Brunton 1990; Brayfield 2014].
Conditions in which easy defecation with soft stools is desirable, e.g. in cases of anal fissures or haemorrhoids [Webster 1978], after rectal or anal surgery, and during pregnancy.
Conditions which need an increased daily intake of fibre, e.g. irritable bowel syndrome [Sölter 1983; Ligny 1988].
Adjuvant symptomatic therapy in cases of diarrhoea from various causes [Bradshaw 1983; Kovar 1983; Sölter 1983; Koch 1984; Hamouz 1984; Qvitzau 1988].

Posology and method of administration

Dosage

Adults and children over 12 years of age: as a laxative, 7-30 g of the seeds [Sölter 1983; Marlett 1987; Ligny 1988, Brayfield 2014] or equivalent preparations daily; in cases of diarrhoea, 20 g up to 40 g daily, divided into 2-3 doses [Sölter 1983].
Children 6-12 years: half the adult dose.

Method of administration
For oral administration.

It is very important to take the seeds with a large amount of liquid, e.g. mix approx. 5 g with 150 ml of cool water, stir briskly and swallow as quickly as possible, then maintain adequate fluid intake.

Ispaghula seed should preferably be taken at mealtimes; it should not be taken immediately prior to going to bed. Any other medications should be taken at least 30-60 minutes before ispaghula seed in order to avoid delayed absorption.

Duration of use
In cases of diarrhoea, medical advice should be sought if the symptoms persist for more than 3 days in order to ensure definitive diagnosis of the cause.

Contraindications
Children under 6 years of age.
Known hypersensitivity to ispaghula seed [Suhonen 1983; Zaloga 1984; Lantner 1990; Brayfield 2014].

Ispaghula seed should not be used by patients with the following conditions unless advised by a physician: faecal impaction; undiagnosed abdominal symptoms; a sudden change in bowel habit that persists for more than 2 weeks; rectal bleeding; failure to defecate following the use of a laxative; abnormal constrictions in the gastrointestinal tract; potential or existing intestinal obstruction (ileus); diseases of the oesophagus and cardia; megacolon [Brunton 1990; Brayfield 2014]; diabetes mellitus which is difficult to regulate [Kay 1978; Cummings 1978; Brunton 1990].

Special warnings and precautions for use
A sufficient amount of liquid should always be taken: at least 150 ml of water per 5 g of seed [Brayfield 2014].

Taking ispaghula seed without adequate fluid may cause it to swell and block the throat or oesophagus and may cause choking. Intestinal obstruction may occur should adequate fluid intake not be maintained. Do not take ispaghula seed if you have ever had difficulty in swallowing or have any throat problems. If you experience chest pain, vomiting, or difficulty in swallowing or breathing after taking it, seek immediate medical attention. Treatment of the elderly and debilitated patients requires medical supervision. Administration to the elderly should be supervised.

In cases of diarrhoea sufficient intake of water and electrolytes is important.

Interactions with other medicinal products and other forms of interaction
Enteral absorption of concomitantly administered minerals (e.g. calcium, iron, lithium, zinc), vitamins (B12), cardiac glycosides and coumarin derivatives may be delayed [Kay 1978; Cummings 1978; Brunton 1990]. For this reason, other medications should be taken at least 30-60 minutes before ispaghula seed. In the case of insulin-dependent diabetes it may be necessary to reduce the insulin dose [Kay 1978; Cummings 1978; Capani 1980; Frati-Munari 1989].

Pregnancy and lactation
No restriction [Lewis 1985].
A risk is not to be expected since the constituents of ispaghula seed are not absorbed and have no systemic effects.

Effects on ability to drive and use machines
None known.

Undesirable effects
Flatulence may occur, but generally disappears during the course of treatment. Abdominal distension and risk of oesophageal or intestinal obstruction and faecal impaction may occur, particularly if ispaghula seed is ingested without sufficient fluid.

There is a risk of allergic reaction from inhalation of the powder during occupational exposure [Busse 1975]. There have been reports of single cases of hypersensitivity with the possible risk of anaphylaxis [Suhonen 1983; Zaloga 1984; Lantner 1990; Brayfield 2014].

Overdose
Overdosage may cause abdominal discomfort and flatulence, or even intestinal obstruction. Adequate fluid intake should be maintained and management should be symptomatic.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties
Note: Due to the fact that the ripe seeds of ispaghula seed contain the epidermis ('husk') with mainly soluble fiber (see Constituents), some pharmacological studies with ispaghula husk are referenced in the following as well.

Ispaghula seed has its effects by absorbing fluid, increasing bulk and so physically stimulating the gut wall. The intraluminal pressure is decreased and colon transit is accelerated, increasing the number of bowel evacuations and softening the stools. Ispaghula seed increases stool weight and water content due to the fibre residue, the water bound to that residue, and the increased faecal bacterial mass [Read 1986, Sharma 1986].

In vivo experiments

Metabolic effects
In rats adapted to a fibre-free, cholesterol-rich diet, dietary starch was replaced for 4 weeks by ispaghula seed or ispaghula husk. Within 2 weeks, ispaghula seed normalized plasma total cholesterol levels which were elevated 5-fold compared to a cholesterol-deficient diet. HDL significantly increased in fibre-free controls from 5% to 47% (in relation to total cholesterol). LDL was greatly reduced (1.14 versus 12.6 mmol/L) and liver cholesterol content significantly lowered (15.5 versus 22.1 µmol/L). Ispaghula seed was as effective as the husks [Leng-Peschlow 1989].

Rats were fed with a diet containing 0.5% cholesterol and 10% fibre (cellulose, pectin, ispagula seed or husk). Two control groups were fed a fibre-free diet, one of which also received 0.5% cholesterol in the diet. Ispaghula seed exerted an effect on total cholesterol equal to that of pectin but resulted in higher HDL levels. The effect on liver lipids was more pronounced than that of pectin. Ispaghula husk normalized serum triglyceride levels and produced lower serum total cholesterol and higher HDL levels compared to normal controls [Kritchevsky 1995].

Rats fed for 4 weeks with a diet supplemented with 10% ispaghula husk had significantly ($p<0.05$) higher levels of faecal bile acids than rats fed a fibre-free diet [Vahouny 1987].

After feeding 3 groups of hamsters of both sexes for 30 days with either a fibre-free diet (n=15), a high fibre diet with cellulose (n=8) or a high fibre diet with ispaghula husk (n=8), proximal, middle and distal regions of the small intestine were analyzed for their digestive-absorptive function of sucrose. Ispaghula husk significantly ($p<0.05$) reduced the level of monosaccharides crossing the intestinal tissue compared with the fibre-free diet, as did cellulose. Uniquely for isphagula however this effect was consistent through all segments of the bowel [Mahapatra 1988].

Male guinea pigs (n = 30; 10 per group) were fed either with a control diet or diets containing 7.5 g or 10 g ispaghula seed per 100g of diet for 4 weeks. Although a dose response was not observed, plasma triglycerides and LDL cholesterol were 34% and 23% lower compared to control ($p<0.01$). Lecithin cholesterol acyltransferase (LCAT) and cholesterol ester transfer protein (CETP) activities were significantly affected in the ispaghula seed treatment groups. The control group showed 100% and 36% higher LCAT and CETP ($p< 0.01$) activities respectively when compared to the ispaghula seed groups. Hepatic total and free cholesterol concentrations were not affected but cholesterol ester concentrations were 50% ($p< 0.01$) lower in the ispaghula seed groups. The activity of 3-hydroxy-3-methylglutaryl coenzyme A reductase (rate-limiting enzyme of cholesterol synthesis) was up-regulated in the treatment groups by 37%. Similarly, the activity of cholesterol 7α-hydroxylase (enzyme of cholesterol catabolism to bile acids) was 33% higher in the treatment groups ($p<0.02$). Faecal bile acids

were 3 times higher in the ispaghula seed groups compared to control [Romero 2008].

Mucosa-protective effects
Rats (n=70; 10 per group) were fed for 4 weeks with a diet supplemented with either 100 g or 200 g of ispaghula seed, ispaghula husk or wheat bran per kg of standard diet, and compared to controls given the fibre-free standard diet only. β-glucuronidase activity of colonic bacteria (potentially producing toxic metabolities from bile), decreased in a time-dependent manner in both ispaghula seed groups, at day 8 reaching 25% of the activity of the control group for the seed and 10% of the activity of the control group for the husk (both $p<0.001$), both having greater impact than wheat bran. Acetate is a short-chain fatty acid released from the digestible part of the fibre by bacterial fermentation, and has a trophic and differentiating effect on the mucosal cell; it was increased significantly ($p<0.001$) in caecal contents of the ispaghula groups compared to the fibre-free control (wheat bran having no significant effect) [Leng-Peschlow 1991].

Similar results have been shown in monkeys in which β-glucuronidase activity was significantly ($p<0.05$) decreased in those fed a diet supplemented with ispaghula husk compared to cellulose over a 3.5 year period [Costa 1989].

Although human clinical evidence is lacking [Yao 2017], elevated β-glucuronidase activity in rats is correlated with increased induction or promotion of colonic carcinogenesis [Bauer 1979; Takada 1982; Sun 1988].

Experiments in rats demonstrated that the microbial production of short-chain fatty acids is required to maintain normal epithelial cell proliferation not only in the hindgut but also in the small intestine [Sakata 1988], where butyrate is needed for normal differentiation of the cells [Muller 1986].

HLA-B27 transgenic rats (as an experimental model for ulcerative colitis) were fed with a fibre supplemented diet (5% ispaghula seed) for 13 weeks before evaluation of the colonic inflammatory status, both histologically and biochemically, and the luminal colonic production of short-chain fatty acids (SCFA, i.e. propionate, butyrate) was quantified. Dietary fibre supplementation ameliorated the development of colonic inflammation by a decrease of pro-inflammatory mediators, e.g. nitric oxide, leukotriene B4, TNFα. The intestinal contents of treated rats compared to non-treated animals showed a significantly higher production of SCFA which was associated with inhibition of production of pro-inflammatory mediators [Rodriguez-Cabezas 2003].

Pharmacological studies in humans

Laxative effects
Gastrointestinal transit time, frequency of defecation, stool weight and stool consistency were studied in 12 women who were each given fibre supplements (40g daily) wheat bran, psyllium gum (ispaghula), a combination of both, or a low fibre control (21g daily) for 2 weeks. Fibre supplementation decreased transit time and increased the daily number of defecations and both the wet and dry weights of stools. Bran had a greater effect on transit time than psyllium; whereas psyllium was superior to bran regarding the amount of water in the stools and the total stool weight. In subjects receiving the control, 50% of the stool ratings were scored as "hard" compared to 10% in those receiving the high-fibre supplements [Stevens 1988].

Metabolic effects
Ispaghula husk (9.6 g daily) was administered for 6 weeks to 2 normally active young adult males after a 4-week pre-experimental control period. Total faecal bile acids per 24 hours averaged 3 times (302%) the excretion level of the control period. Serum cholesterol levels averaged 17% lower than during the control period ($p<0.005$) [Forman 1968].

Clinical studies

Constipation
In a short-term study, 42 adults (aged 18 to 35) with a history of chronic constipation and having ≤3 bowel movements during one week of a single blind placebo treatment were randomized to receive either 7.2 g of ispaghula husk per day or a combination of ispaghula seed plus senna (6.5 g + 1.5 g per day) for 14 days. Both laxatives increased defecation frequency although the added effect of senna was clearly evident. Constipation was assessed by stool frequency and weight, with laxation attained by 63% of the ispaghula/senna combination group and 48% of the ispaghula husk group alone [Marlett 1987].

In 15 short-term open controlled clinical trials 669 patients in total (266 males and 403 females; aged 13 to 90 years) were treated with ispaghula seed (product containing 65 g ispaghula seed with 2.2 g ispaghula husk and excipients up to 100 g of finished product) for 7 days. The standard daily dose of the product administered with a glass of cold water was 10 g before the evening meal and if necessary an extra 5 g before breakfast. Number of daily bowel evacutions, stool consistency and associated symptoms were noted on days 1, 3, 4 and 7. 309 patients with constipation (in some cases post surgery), 74 pregnant women, 116 patients with haemorrhoids (including post surgery), anal fissures and abscesses as well as 142 patients with constipation from various reasons (in total 641 patients) were suitable for assessment [Sölter 1983].

In the short-term trial with the largest number of patients (200 of which 197 considered for evaluation) treatment of constipation in bedridden patients (n = 89) was studied. After 1 day of treatment 74% of the patients had at least one bowel movement, after 3 days bowel movement was achieved in 92% and after 7 days in 99% of the cases. In 27 other patients constipation post surgery was treated and success rates of 48%, 100%, 100% and 100% were noted on days 1, 3, 4 and 7 respectively [Sölter 1983].

Of 28 patients treated with the ispaghula seed combination because of haemorrhoids, anal fissures and abscesses at least one bowel movement started already on the first day of treatment in 82% and by the third day in 96% of cases [Sölter 1983].
In 17 patients with recent hemorrhoidectomy or other anal operations, defecation began in 35%, 94%, 100% and 100% of the patients on days 1, 3, 4 and 7 respectively [Sölter 1983].
To summarize the results in the remaining short-term trials, a response to treatment in the form of at least one daily bowel evacuation was achieved in 53% on the first day, in 83% on the third day and in 90% of the patients on the fourth day of treatment [Sölter 1983].

Regarding the parameter "changes in stool consistency (measured in a 5 point scale from liquid to no evacution)" the result of all 15 short-term trials was a significant effect ($p<0.01$; at least 0.69 scale units) in 7 of 13 trials.

Regarding stool consistency a significant improvement was noted in constipation in pregnancy, in 3 of the 4 studies ($p<0.01$) [Sölter 1983].

In a 3-center long-term open clinical trial 139 patients (59 males and 80 females; 136 suitable for assessment; aged 9 to 80 years) were treated with the same daily dose as in the

short-term trials over periods of up to 12 weeks (110 patients were treated for the full 12 weeks, the others dropped out because they no longer required medication but were however included for evaluation). Number of daily bowel evacuations and stool consistency improvement were noted on day 8 and at 4, 8 and 12 weeks. The total number of patients successfully treated regarding number of daily bowel evacuations and stool consistency was 123 (88.4%) [Sölter 1983].

Irritable bowel syndrome
In a randomized, double blind, placebo controlled clinical study, 60 patients with irritable bowel syndrome were treated 4 times daily for 30 days with a combination of ispaghula seed (3.25 g per dose) and husk (0.11 g per dose) or placebo, after meals and before going to bed (total daily dose:13.0 g of seed and 0.44 g of husk). Patients were allowed to take a concomitant antispasmodic at doses of up to 5 tablets daily. The number of tablets taken and severity of condition were assessed. After 15 days of treatment there was a significant ($p<0.05$) improvement in both groups. After 30 days of treatment, 27 out of 30 patients in the ispaghula group claimed a symptomatic improvement, their antispasmodic requirements dropped by more than 50%. In the placebo group, 19 out of 30 patients showed an improvement in symptoms but their antispasmodic intake remained as high as before the trial [Ligny 1988].

Diarrhoea
In an open study, 36 patients (28 females, 8 males) with symptoms of diarrhoea for 2 days (on average 7 evacuations before starting therapy) were treated with a combination of ispaghula seed (6.5 g) and husk (0.22 g) 3 times daily (total daily dose 19.5 g of seed and 0.66 g of husk). Frequency of bowel evacuations was reduced on the first day of treatment to an average of 3 and to <2 on the second day of treatment. On day 3 only one patient had more than 1 evacuation [Kovar 1983].

In an open, controlled study, 50 inpatients with acute (n=22) and chronic (n=28) diarrhoea were treated for 3 days with a combination of ispaghula seed (6.5 g per dose) and husk (0.22 g per dose) 3 times daily (total daily dose 19.5 g of seed and 0.66 g of husk) and individually dosed for a further 4 days. Firming of stools and a reduction of evacuation frequency were established on day 3 in all patients. On day 7 diarrhoea symptoms were no longer present, with no recurrence one week after discontinuation of treatment [Hamouz 1984].

In an open, randomized, crossover study, 25 patients (18 females and 7 males) with chronic diarrhoea were treated either with loperamide (4 mg daily initially and 2 mg after each loose stool with a maximum of 16 mg per day) or ispaghula husk and calcium (husk/calcium carbonate/calcium hydrogen phosphate in a weight ratio of 4:1:1; 5 g twice daily). The median duration of diarrhoea was 12 months (range: 0.5 – 360 months). After 7 days of treatment with either loperamide or ispaghula husk-calcium, treatment was stopped. When diarrhoea recurred, the alternative treatment was started for a further 7 day period. Treatment sequence was decided randomly. Before treatment, the median number of daily stools was 7 (range: 4-13). Both treatments reduced stool frequency by 50%, but the ispaghula husk/calcium was significantly ($p<0.05$) more effective with regard to urgency and stool consistency [Qvitzau 1988].

In an open, controlled study, 84 hospital inpatients with diarrhoea (48 psychiatric patients and 36 nursing home patients) were treated for up to 3 days with a combination of ispaghula seed (6.5 g) and husk (0.22 g) 3 times daily (total daily dose 19.5 g of seed and 0.66 g of husk). The dose was then reduced to 3.25 g of seed and 0.11 g of husk 3 times daily (total daily dose 9.75 g of seed and 0.33 g of husk), if necessary.

In the study group of psychiatric patients (28 females and 20 males), 20 had acute and 28 had chronic diarrhoea. During treatment of the subgroup with chronic diarrhoea, the ispaghula combination showed a good response in 16 cases and an adequate response in 8 others. After one week of treatment, the average daily frequency of bowel movements was reduced from 3.4 (before treatment) to 1.5.

In the 20 psychiatric patients with acute diarrhea, stool frequency decreased from a daily average of 4.7 before treatment to 2.3 on the third day of treatment.

The nursing home patients (28 females and 8 males, age 40 to 90 years) were all suffering from acute diarrhoea. Before treatment, average daily stool frequency was 6.94 which dropped to 3.28 on the first day of treatment and to 2 on the third day. All stools were soft but formed or solid, and there were no accompanying symptoms [Sölter 1983].

In a randomized, controlled, crossover study, 30 patients with Crohn's disease were either treated after their hospital stay with a combination of ispaghula seed (3.25 g per dose) and husk (0.11 g per dose) 2 times daily (in total 6.5 g of seed and 0.22 g of husk) or remained untreated. Treatment with the ispaghula combination was discontinued in the first group after 3 months, and subsequently given for a further 3 months to the previously untreated group. Both arms of the study were completed by 20 patients. Disregarding the periods of active inflammatory exacerbation, the average number of daily bowel evacuations significantly ($p<0.01$) decreased with the ispaghula seed combination from 2.71 to 2.0 per day. Including the periods of active inflammation, the average number of evacuations dropped from 3.79 to 2.19 per day ($p<0.01$) [Sölter 1983, Koch 1984].

Lipid lowering activity
Chronic inpatients (6 of each sex, aged between 57 and 76), suffering all but one from constipation and being confined to bed, were given up to 15-18 g of ispaghula husk shortly before breakfast for 16 weeks. Stool consistency and ease of passage significantly improved in all patients. In all but 2 patients a decrease in serum cholesterol also occurred. The mean cholesterol level was significantly ($p<0.005$) reduced from 6.1 to 5.1 mmol/L [Burton 1982].

In a double-blind, placebo-controlled, parallel study, 28 men with mild to moderate hypercholesterolemia (range: 4.86 to 8.12 mmol/L) were treated for 8 weeks with 3.4 g of ispaghula husk, or cellulose as placebo, three times daily at mealtimes. Ispaghula husk significantly reduced total cholesterol by 14.8%, from 6.39 to 5.45 mmol/L ($p<0.05$), and LDL by 20.2%, from 4.18 to 3.34 mmol/L ($p<0.05$) [Anderson 1988].

Mildly hypercholesterolemic male and female adults (n=28) were administered ispaghula seed (4.06 g twice daily p.o.) for 3 months. Compared to pre-treatment values total cholesterol was reduced by 7.2% ($p<0.007$) and LDL by 13% ($p<0.0003$), while the other parameters including HDL, triglycerides and urea nitrogen remained unaffected [Segawa 1998].

Hypoglycemic effects
In an open, randomized, crossover study, 20 postgastrectomy patients received a glucose solution with or without ispaghula husk to determine its effects on blood glucose and breath hydrogen. In the high responder group (n=15; 20 ppm hydrogen/2h) the mean hydrogen response was 78 ppm/2h with the glucose meal and reached a blood glucose level of 195 mg/dl. The mean hydrogen response was reduced 20 ppm/2h following a glucose meal with ispaghula husk and blood glucose level decreased to 153 mg/dl. The differences were significant ($p<0.05$) [Welsh 1982].

In an open, controlled trial, 19 male and 21 female outpatients (aged 39 to 77 years) suffering from constipation and non-insulin dependent diabetes were allocated into 2 treatment groups, receiving either 3.6 g or 7.2 g ispaghula husk daily for 2 months. After this period all patients received 10.8 g of ispaghula husk daily for a further 2 months. Fasting glucose after 3.6 g of ispaghula husk decreased from an average of 10.9 mmol/l to 8.8 ($p<0.01$) and after 7.2 g of ispaghula husk from 10.7 to 8.8 ($p<0.01$). After 4 months of treatment the average was significantly ($p<0.001$) reduced to 8.8 mmol/l glucose from a starting average of 10.8 mmol/l [Fagerberg 1982].

Pharmacokinetic properties
The vegetable fibre of ispaghula seed is resistant to digestion in the upper intestinal tract; thus it is not absorbed. Part of the fibre is degraded by colonic bacteria in the lower intestinal tract to short-chain fatty acids, methane or carbon dioxide [Kay 1978].

Preclinical safety data
No data available.

Clinical safety data

Constipation
Among the symptoms of constipation are gaseous distension, abdominal pain, nausea and vomiting. The same symptoms may arise from medication with a bowel-regulating agent like ispaghula seed. Therefore it is often difficult to distinguish between a symptom due to constipation and a side effect due to a bulk laxative. In short-term clinical trials with 669 patients with constipation of various aetiologies, the most commonly reported symptoms were gaseous distension, and occasionally abdominal pain and slight nausea which disappeared with continuation of treatment [Sölter 1983].

Adverse effects also occurred in a long-term study over 12 weeks in 92 out of 139 patients, mainly in the first 2 weeks of treatment in the form of gaseous distension and abdominal pain, but tended to subside as treatment was continued. Proctoscopy, carried out in a random sample of patients (n = 9) during the 12 weeks of treatment, showed no macroscopic or histological evidence of any changes in the rectal mucosa. Checks of electrolyte levels, also in random samples, showed no changes in potassium, sodium or calcium levels [Sölter 1983].

Diarrhoea
In open clinical studies with a total of 170 patients with acute and chronic diarrhoea of various origin, an ispaghula seed and husk combination was well tolerated. Gaseous distension occurred in most cases on the first day of treatment but disappeared when treatment was continued [Kovar 1983; Sölter 1983; Hamouz 1984].

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

PLANTAGINIS OVATAE TESTA 2016

Ispaghula Husk, Blond Psyllium Husk

DEFINITION

Ispaghula husk consists of the episperm and collapsed adjacent layers removed from the seeds of *Plantago ovata* Forssk. (*P. ispaghula* Roxb.).

The material complies with the monograph of the European Pharmacopoeia [Ispaghula Husk].

CONSTITUENTS

Dietary fibre, principally as mucilage polysaccharide consisting of a highly-branched arabinoxylan with a xylan backbone and branches of arabinose, xylose and 2-*O*-(galactosyluronic acid)-rhamnose residues [Kennedy 1979; Sandhu 1981; Hänsel 1999; Marlett 2003; Fischer 2004].

CLINICAL PARTICULARS

Therapeutic Indications
Treatment of occasional constipation [Sweetman 2002; Brunton 1990; Kay 1978; Borgia 1983; Stephen 1980; Marlett 1987; Thorburn 1992; McRorie 1998; Wang 2004].
Conditions in which easy defaecation with soft stools is desirable, e.g. in cases of anal fissures or haemorrhoids [Webster 1978; Kecmanovic 2006], after rectal or anal surgery [Eogan 2007], and during pregnancy.
Conditions which need an increased daily intake of fibre, e.g. irritable bowel syndrome [Prior 1987; Golecha 1982; Kumar 1987; Bijkerk 2009; Ford 2008].
Adjuvant symptomatic therapy in cases of diarrhoea from various causes [Bradshaw 1983; Qvitzau 1988; Hamouz 1984; Bobrove 1990; Smalley 1982; Frank 1979; Eherer 1993].
As an adjunct to a low fat diet in the treatment of mild to moderate hypercholesterolaemia [Bell 1989; Levin 1990; Anderson 1991; Sprecher 1993; Weingand 1997; Anderson 2000a; MacMahon 1998; Anderson 2000b; Ciba 1992a/b/c; Ciba 1993a/b/c; Neal 1990; Bell 1990; Anderson 1992; Roberts 1994; Stoy 1993; Wolever 1994a; Summerbell 1994; Jenkins 1997; Olson 1997; Davidson 1998; Davidson 1996; Spence 1995; Anderson 1988; Everson 1992; Rodriguez-Morán 1998; Gupta 1994; FDA 1998; Ganji 2008; Uehleke 2008; Jayaram 2007; Jenkins 2002; Solà 2010].

Posology and method of administration

Dosage
Adults and children over 12 years of age: 4-20 g daily, divided into 2-3 doses.
Children 6-12 years: half the adult dose.

Special Dosage Instructions
For the treatment of hypercholesterolaemia approx. 10 g of ispaghula husk should be given daily in 2 or 3 doses [Bell 1989; Levin 1990; Anderson 1991; Sprecher 1993; Weingand 1997; Anderson 2000a; MacMahon 1998; Anderson 2000b; Ciba 1992a/b/c; Ciba 1993a/b/c; Bell 1990; Anderson 1992; Roberts 1994; Stoy 1993; Summerbell 1994; Jenkins 1997; Olson 1997; Davidson 1998; Anderson 1988; FDA 1998].

Method of administration
For oral administration.

It is very important to take the material with a large amount of liquid, e.g. mix approx. 5 g with 150 ml of cool water, stir briskly and swallow as quickly as possible, then maintain adequate fluid intake.

Ispaghula husk should preferably be taken at mealtimes; it should not be taken immediately prior to going to bed. Any other medications should be taken at least 30-60 minutes before ispaghula husk in order to avoid delayed absorption.

Duration of administration
In cases of diarrhoea, medical advice should be sought if the symptoms persist for more than 3 days in order to ensure definitive diagnosis of the cause.

Contraindications
Children under 6 years of age.

Known hypersensitivity to ispaghula husk [Sweetman 2002; Brunton 1990; Zaloga 1984; Suhonen 1983; Lantner 1990].

Ispaghula husk should not be used by patients with the following conditions unless advised by a physician: faecal impaction; undiagnosed abdominal symptoms; a sudden change in bowel habit that persists for more than 2 weeks; rectal bleeding; failure to defaecate following the use of a laxative; abnormal constrictions in the gastrointestinal tract; potential or existing intestinal obstruction (ileus); diseases of the oesophagus and cardia; megacolon [Sweetman 2002; Brunton 1990]; diabetes mellitus which is difficult to regulate [Brunton 1990; Kay 1978; Cummings 1978].

Special warnings and special precautions for use
A sufficient amount of liquid should always be taken: at least 150 ml of water per 5 g of material [Thorburn 1992].

If you experience chest pain, vomiting, or difficulty in swallowing or breathing after taking ispaghula husk, seek immediate medical attention. Administration to the elderly should be supervised. In cases of diarrhoea sufficient intake of water and electrolytes is important.

Interactions with other medicaments and other forms of interaction
Enteral absorption of concomitantly administered minerals (e.g. calcium, iron, lithium, zinc), vitamins (B12), cardiac glycosides and coumarin derivatives may be delayed [Brunton 1990; Kay 1978; Cummings 1978; Perlmann 1990]. For this reason, other medications should be taken at least 30-60 minutes before ispaghula husk. In the case of insulin-dependent diabetics it may be necessary to reduce the insulin dose [Kay 1978; FDA 1998; Fagerberg 1982; Capani 1980; Frati-Munari 1989; Abraham 1988].

Fertility, pregnancy and lactation
No restriction.

A risk is not to be expected since the components of ispaghula husk are not absorbed and have no systemic effects [Lewis 1985].

Effects on ability to drive and use machines
None known.

Undesirable effects
Flatulence may occur, but generally disappears during the course of the treatment. Abdominal distension and risk of oesophageal or intestinal obstruction and faecal impaction may occur, particularly if ispaghula husk is ingested without sufficient fluid.

There is a risk of allergic reaction from inhalation of the powder during occupational exposure. Due to the allergic potential of ispaghula husk, patients must be aware of reactions of hypersensitivity including anaphylactic reactions in single cases [Zaloga 1984; Suhonen 1983; Lantner 1990].

Overdose
Overdose may cause abdominal discomfort and flatulence, or even intestinal obstruction. Adequate fluid intake should be maintained and management should be symptomatic.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

Dietary fibre such as ispaghula husk binds water and swells to form a demulcent gel or viscous solution in the intestine. By virtue of binding water in the colon, the faeces are softened and their bulk increased, thus promoting peristalsis and reducing transit time [Stephen 1980; Marlett 1987; Brunton 1990; Sweetman 2002]. Degradation products of dietary fibre resulting from bacterial action in the colon may also contribute to the laxative effect [Kay 1978; Brunton 1990].

The ability to absorb abundant water and to convert fluid in the intestine into a more viscous mass also makes ispaghula husk useful for the symptomatic relief of acute diarrhoea, enabling the patient to pass a formed stool [Smalley 1982; Bradshaw 1983; Brunton 1990].

In vitro experiments
After anaerobic fermentation of ispaghula husk with colonic bacteria, induction of apoptosis was induced in all primary tumour and metastatic cell lines of colorectal cancer cells, independent of p53, adenomatous polyposis coli, β-catenin or cyclo-oxygenase-2 status [Sohn 2012].

In vivo experiments
Ispaghula husk reduces experimentally-induced hyperlipidaemia and atherosclerosis in animals [Turley 1994; Turley 1991; McCall 1992a; Gallaher 1993; Matheson 1995; Horton 1994; Fernandez 1995; Arjmandi 1992; Matheson 1994; McCall 1992b]. Beneficial changes in serum lipid and lipoprotein profiles were greater in rats fed a mixture of ispaghula husk and margarine (rich in *trans*, as well as *cis*, fatty acids) than in rats fed a mixture of ispaghula husk and corn oil/olive oil (rich in *cis*, but free from *trans*, fatty acids) [Fang 2000].

In 2 groups of rabbits fed for 4 weeks with either standard feed (group 1; n=18) or with feed supplemented with ispaghula husk (3.5 mg/kg/d) (group 2; n=18), biochemical parameters were determined on day 14 after a glucose load of 3g. Alloxan was then used to induce experimental diabetes and animals were analysed after a further glucose load on day 28. In healthy animals, at day 14, the addition of ispaghula husk to feed had not modified glucose concentrations. On day 28, the diabetic animals (subdivided into mild and severe diabetes) fed with ispaghula husk had decreased glucose concentrations which were more pronounced in rabbits with mild diabetes (21.7%; $p<0.05$) than in rabbits with severe diabetes (9.6%; not significant). All other biochemical parameters were lower in group 2 than in group 1 (standard diet) although differences were significant only for total cholesterol, LDL and Hb1Ac ($p<0.05$) [Díez 2013].

Similar experiments in obese Zucker rats (model for metabolic syndrome) showed that ispaghula husk is more beneficial than insoluble fiber such as cellulose or methylcellulose [Galisteo 2010].

Ispaghula husk had little or no effect on the faecal excretion of neutral steroids or on cholesterol absorption [Turley 1994; Turley 1991; McCall 1992a] but apparently enhanced bile acid loss, due to its gel-forming ability and its viscosity [Gallaher 1993; Matheson 1995].

In C57BL/6J mice, the transcriptional response regarding genes encoding enzymes regulating key steps of lipid metabolism and their protein expression were tested 3 and 10 weeks after a control diet or a high fibre diet containing 10% ispaghula husk. In the verum group, plasma total cholesterol ($p<0.05$)

and triacylglycerol ($p<0.05$) levels were reduced which was most likely mediated by increased bile acid synthesis. After 3 weeks, genes involved in lipogenesis were downregulated, whereas those involved in cholesterol and bile acid synthesis were upregulated. With prolonged ispaghula husk feeding, genes involved in lipogenesis and the respective protein expression levels were significantly upregulated which could likely suggest a regulatory mechanism to restore the lowered plasma cholesterol and triacylglycerol levels [Chan 2008].

Male hamsters were fed for 4 weeks with a high n-3 PUFA (polyunsaturated fatty acid) diet including either ispaghula husk or methyl cellulose at 80 mg/kg of feed, and enriched with variable levels of cholesterol (0, 0.05, 0.1%, w/w). Plasma total cholesterol and LDL were significantly ($p<0.05$) lower for ispaghula husk compared to methyl cellulose in only the 0.1% cholesterol group. In a further experiment, hamsters were divided into four groups, two given a diet high in n-3 PUFA and 2 high in n-6 PUFA, all diets contained 0.2 % cholesterol and either psyllium husk or methyl cellulose at 80 mg/kg of feed. Psyllium husk led to significantly ($p<0.05$) lower plasma total cholesterol and VLDL-cholesterol levels when compared to methyl cellulose in only the hamsters fed the n-3 PUFA diet, whereas hepatic total cholesterol was significantly ($p<0.05$) lower for ispaghula husk compared to methyl cellulose in the n-3 and n-6 PUFA diet groups [Liu 2004].

Ispaghula husk was shown to increase the activity of hepatic 7α-hydroxylase, the initial and rate-limiting enzyme in the conversion of cholesterol to bile acids [Matheson 1995; Horton 1994; Fernandez 1995]. The conversion of hepatic cholesterol into bile acids has been established as a mechanism for reducing serum cholesterol [Matheson 1995; Arjmandi 1992; Matheson 1994] with a net negative sterol balance across the liver [Turley 1994].

A study testing various diets in guinea pigs investigated the mechanisms by which ispaghula husk influences plasma low-density lipoprotein (LDL) concentrations. Ispaghula husk altered hepatic cholesterol homeostasis by increasing the activity of HMG-CoA reductase ($p<0.001$) and reducing hepatic acyl-CoA:cholesterol acyltransferase activity ($p<0.001$). It increased hepatic membrane apoB/E receptor number ($p<0.005$), reduced plasma LDL concentrations ($p<0.001$) and modified LDL composition and size compared to LDL from control animals. The LDL from treated animals had a lower proportion of cholesteryl ester, a higher proportion of triacylglycerol, a lower molecular weight, a smaller diameter and a higher peak density ($p<0.001$) [Fernandez 1995].

Anti-carcinogenic effects
ICR:CD1 female mice exposed to carcinogenesis with azoxymethane (10mg/kg b.w. for 6 weeks) were fed with a diet containing 0.7% ispaghula husk. Two weeks after the last azoxymethane (AOM) injection, the caecum, colon and rectum were inspected for early precursor lesions of colorectal cancer such as Aberrant Crypt Foci (ACF), Mucin Depleted Foci (MDF) and Beta-Catenin-Accumulated Crypts (BCAC). ACF, BCAC and low-grade dysplasia were observed in the intestinal mucous membrane from AOM-treated animals, both with and without ispaghula supplementation, while MDF and high grade dysplasia were seen only in AOM-treated control animals fed with standard diet. Differences were not significant between the groups but the ispaghula supplement group had a trend towards reduced lesions [Díez-Liébana 2009].

Pharmacological studies in humans
In 10 healthy subjects, 20 g of ispaghula husk per day significantly decreased fat digestibility ($p<0.05$) and increased faecal fat excretion ($p<0.05$) [Ganji 1994]. However it did not affect faecal steroid excretion (neutral steroids and bile acids) [Abraham 1988; Gelissen 1994]. In16 healthy volunteers consuming 7 g of ispaghula husk per day for 8 weeks, faecal lithocholic and isolithocholic acids and the weighted ratio of lithocholic to deoxycholic acid were significantly lower after treatment. These changes in faecal bile acid profiles indicate a reduction in the hydrophobicity of bile acids in the enterohepatic circulation [Chaplin 2000].

In a placebo-controlled, crossover design study with a 21 day washout period, 68 healthy volunteers (24 male, 23 premenopausal female, 21 postmenopausal female) received 15g of ispaghula husk or placebo daily for 30 days. Mononuclear cell LDL receptor mRNA was not significantly modified by the ispaghula husk in any group compared to control. In contrast, HMG-CoA reductase mRNA was significantly ($p<0.05$) increased in the ispaghula husk groups by 8, 27 and 25% respectively in the men, pre- and postmenopausal women. Although ispaghula husk increased mononuclear cell lipoprotein lipase mRNA in men by 24% ($p<0.05$), postmenopausal women experienced a 23% decrease ($p<0.05$) whereas premenopausal women were not affected [Vega-López 2003].

Using radiotelemetry in patients with left sided diverticular disease, it was shown that ispaghula husk stimulates colonic motility and thus reduces mouth to rectum transit time, predominantly by decreasing the duration of right colonic transit [Thorburn 1992].

Clinical studies

Laxative effect
In a 2-week randomized study, the effects of ispaghula husk (2 × 5.1 g per day) were compared with those of docusate sodium (200 mg per day) in 170 patients suffering from chronic idiopathic constipation. Ispaghula husk was significantly superior to docusate sodium for softening stools by increasing stool water content and had greater overall laxative efficacy [McRorie1998].

In a randomised, controlled, open study with parallel group design male and female patients with chronic functional constipation were treated for 2 weeks with either low-dose polyethylene glycol plus electrolytes (PEG+E; 13.8g dissolved in water twice daily; n=63) or ispaghula husk (3.5g dissolved in water twice daily; n=63). The weekly defecation rates after treatment for 1 or 2 weeks were all statistically significant ($p<0.001$) compared to baseline for both groups and timepoints. In the PEG+E group the mean weekly defecation rate increased from 1.18 at baseline to 7.95 after 1 week and 8.48 after 2 weeks; in the ispaghula husk group it increased from 1.33 at baseline to 5.33 after 1 week and 5.71 after 2 weeks. After 2 weeks of treatment with PEG+E and ispaghula husk the stool was normalized in 55 out of 63 (87.3%) and 42 out of 63 (66.7%) patients respectively. The absolute mean values and increases of defecation rate achieved after both 1 and 2 weeks were all significantly greater in the PEG+E group than those in the ispaghula husk group ($p<0.001$) [Wang 2004].

For reduction of constipation in people prescribed opioids, a review up to the year 2009 found no clinically relevant results from randomised controlled studies with ispaghula husk [Ahmedzai 2010].

Conditions in which easy defecation is desired
Consistency of the faeces, ease of defecation and general bowel habit were significantly improved ($p<0.01$) in 53 patients with

haemorrhoids after a 6-week course of 2 × 3.5 g of ispaghula husk daily when compared to results from the 6-week placebo phase in a double-blind, crossover study [Webster 1978].

In a randomised, clinical trial involving 98 patients with grade III and IV haemorrhoids undergoing open haemorrhoidectomy, subjects were divided into two groups of 49 patients and treated postoperatively for 20 days with either 2 sachets daily of 3.26 g of ispaghula husk or glycerin oil as control. The individual pain score was significantly lower in the ispaghula husk group compared to control at the first bowel movement after surgery ($p<0.001$) and after 10 days ($p<0.01$); there was no significant difference in pain level after 20 days ($p>0.05$). Patients in the verum group had a significantly shorter mean hospital stay of 2.6 days ($p<0.001$) compared to the control group with 3.9 days [Kecmanovic 2006].

In a randomised clinical study involving 147 post partum women who had sustained anal sphincter injury at vaginal birth, one group (n=77) received lactulose alone three times daily for the first 3 postpartum days followed by sufficient lactulose over the following 10 days compared to a group (n=70) with the same lactulose regimen and an additional sachet of ispaghula husk (3.5 g) per day. Pain scores were similar in both groups and the additional treatment did not show any additional benefit [Eogan 2007].

Conditions requiring increased fibre intake, e.g. irritable bowel syndrome (IBS)
In another controlled crossover study a significant improvement ($p<0.05$) was observed from overall assessment after patients with irritable bowel syndrome (IBS) had taken ispaghula husk for 3 weeks, the best results being obtained in spastic colitis ($p<0.01$) and relief in severity of abdominal pain ($p<0.05$) [Golecha 1982]. Ispaghula husk was also shown to alleviate the symptoms of left-sided diverticular disease [Thorburn 1992].

In a randomised, placebo-controlled clinical trial 275 patients with IBS received either 10 g of ispaghula husk (n=85), 10 g of bran (insoluble fiber; n=97) or placebo (rice flour; n=93), taken with meals in two daily dosages for 12 weeks. The primary endpoint was adequate symptom relief analysed after 1, 2 and 3 months of treatment and secondary endpoints included IBS symptom severity score (validated visual analogue scale relating five aspects of bowel dysfunction to actual intensity of IBS symptoms), severity of abdominal pain (measured by means of first question of IBS symptom severity score), and IBS quality of life scale (validated in various populations). The 3 month treatment period was completed by 54 (64%) of the patients in the ispaghula husk group, 54 (56%) in the bran group and 56 (60%) in the placebo group. The primary outcome, as measured by the proportion of responders (with more than 2 weeks of adequate relief in previous 4 weeks) was significantly greater in the ispaghula husk group compared to placebo after 1 month (57% versus 35%) and after 2 months (59% versus 41%). After 3 months the difference compared to placebo was significant for the bran group (57% versus 32%) but not the ispaghula husk group. After 3 months of treatment symptom severity was significantly ($p = 0.03$) reduced by 90 points in the ispaghula husk group compared to 49 points in the placebo group, and non-signficantly decreased by 58 points ($p = 0.61$) in the bran group. No significant differences were found between the three groups with respect to changes in severity of abdominal pain related to IBS or in quality of life [Bijkerk 2009].

A review up to 2008 analysed 6 randomised clinical trials in order to determine the effect of ispaghula husk in the treatment of IBS. Persistent symptoms remained after treatment in 83 patients (52%) out of 161 receiving ispaghula husk compared to 103 out of 160 (64%) receiving placebo, showing some efficacy for ispaghula husk in treating IBS. However, only 5 of the studies had a Jadad score of 4 or more leaving the effect of ispaghula husk as no longer statistically significant [Ford 2008].

Antidiarrhoeal effect
In a crossover study 9 volunteers with diarrhoea induced by phenolphthalein were consecutively treated in a random sequence with 18 g of ispaghula husk, 6 g of calcium polycarbophil, 42 g of unprocessed wheat bran or placebo daily for 4 days. Only ispaghula husk treatment made stools firmer ($p<0.01$) and increased faecal viscosity ($p<0.001$). In a dose-response study in 6 subjects, doses of 9, 18 and 30 g of ispaghula husk per day caused a near linear increase in faecal viscosity [Eherer 1993].

Cholesterol-lowering effects
A meta-analysis has been conducted on 5 published studies [Bell 1989; Levin 1990; Anderson 1991; Sprecher 1993; Weingand 1997] and 3 unpublished studies involving a total of 656 subjects with mild to moderate hypercholesterolaemia (384 in ispaghula husk groups and 272 in placebo groups); 7 studies used a randomized, double-blind, placebo-controlled design, while one study [Weingand 1997] used a crossover design. All the studies met the following criteria: ispaghula husk was used as an adjunct to an American Heart Association (AHA) Step 1 diet (i.e. a diet with no more than 30% of calories from total fat, less than 10% calories from saturated fat, and less than 300 mg of cholesterol daily) with a pretreatment dietary lead-in period of 8-12 weeks; the subjects consumed 10.2 g of ispaghula husk daily in 2 or 3 divided doses for 8 weeks (4 studies), or 12-26 weeks (4 studies). The conclusions were that ispaghula husk significantly lowered serum total cholesterol concentrations by an additional 3.9% ($p<0.0001$) and serum LDL-cholesterol concentrations by an additional 6.7% ($p<0.0001$) relative to placebo in subjects already consuming a low fat diet. Ispaghula husk also significantly lowered serum ratios of apolipoprotein B to apolipoprotein A-I by an additional 6% ($p<0.05$) relative to placebo, but had little effect on serum HDL-cholesterol or triglyceride concentrations [Anderson 2000a].

340 patients with mild to moderate hypercholesterolaemia entered an initial 8-week diet-only period followed by a 12-week randomized, double-blind comparison of ispaghula husk and placebo groups. Ispaghula husk at daily doses of 7.0 g ($p = 0.009$) and 10.5 g ($p<0.001$) produced significantly greater reductions in serum LDL-cholesterol levels (8.7% and 9.7% respectively) than did placebo (4.3%). At both dose levels ispaghula husk also produced significantly greater reductions in total cholesterol levels than did placebo (7.0 g/day versus placebo, $p = 0.040$; 10.5 g/day versus placebo, $p = 0.010$) [MacMahon 1998].

The long-term cholesterol-lowering effect of ispaghula husk as an adjunct to diet therapy (AHA Step 1) was evaluated in a randomized, double-blind, placebo-controlled study involving 248 subjects with primary hypercholesterolaemia. After 24-26 weeks, daily treatment with 10.2 g of ispaghula husk had significantly reduced ($p<0.001$) serum total cholesterol (4.7%) and LDL-cholesterol (6.7%) compared to placebo [Anderson 2000b].

In a randomized, double-blind study in patients with mild to moderate hypercholesterolaemia, 2 × 5.1 g of ispaghula husk daily for 16 weeks as an adjunct to a low fat diet (AHA Step 1) significantly reduced total cholesterol ($p<0.02$), LDL-cholesterol ($p<0.01$) and apolipoprotein B ($p<0.04$) in comparison with placebo or diet alone [Ciba 1992a/b/c]. An open, 28-week extension of this study confirmed the reductions in total

cholesterol and LDL-cholesterol after taking 2 × 5.1 g of ispaghula husk daily in conjunction with a low fat diet [Ciba 1993a/b/c].

These results [Bell 1989; Levin 1990; Anderson 1991; Ciba 1992a/b/c; Ciba 1993a/b/c; Sprecher 1993; Weingand 1997; MacMahon 1998; Anderson 2000b] and another study [Neal 1990] showed that, where a good reduction of blood lipids has already been achieved by use of a low fat diet, a further reduction is possible by taking ispaghula husk as an adjunct to the diet.

Another meta-analysis was performed to determine the effects of ispaghula husk-enriched cereal products on blood total cholesterol, and LDL- and HDL-cholesterol levels, in mild to moderate hypercholesterolaemic adults who consumed a low fat diet. The 8 published [Bell 1990; Anderson 1992; Roberts 1994; Stoy 1993; Wolever 1994a; Summerbell 1994; Jenkins 1997] and 4 unpublished studies included, involving a total of 404 patients, met the criteria of randomized, controlled studies in adults using either a crossover design (7 studies) or a design with parallel arms (5 studies) to compare treatment and control conditions for determining the effects of ispaghula husk-enriched cereals on blood lipids, with control groups that ate cereals providing ≤3 g of soluble fibre per day. Three studies [Roberts 1994; Summerbell 1994 and one of the unpublished studies] had no dietary lead-in period whereas the others had a 3- to 6-week dietary lead-in period, during which time the subjects were instructed to adhere to a low fat diet. The daily dose of ispaghula husk was 9.4-12 g in 9 studies, but lower (3.0, 6.7 and 7.6 g) in the other 3 studies. The conclusions from this meta-analysis were that treatment with ispaghula husk-enriched cereals significantly lowered total cholesterol (by 5%; $p<0.0002$) and LDL-cholesterol (by 9%; $p<0.0001$) but had no effect on HDL-cholesterol. The results confirmed that consuming an ispaghula husk-enriched cereal as part of a low fat diet improves the blood lipid profile of hypercholesterolaemic adults beyond that which can be achieved with a low fat diet alone [Olson 1997].

The results of a randomized, double-blind, controlled study in patients with mild to moderate hypercholesterolaemia suggested that consumption of foods containing 10.2 g of ispaghula husk daily in conjunction with a low fat diet (AHA Step 1) results in the maintenance of reduced LDL-cholesterol concentrations without affecting HDL-cholesterol or triacylglycerol concentrations. At the conclusion of the 24-week treatment period, the mean LDL-cholesterol concentration was 5.3% lower in the verum group than in the control group ($p<0.05$) [Davidson 1998].

After 8 weeks of diet stabilisation, the effects of an ispaghula husk-enriched cereal (providing 6.4 g of ispaghula husk per day) or a matched control cereal, administered during 6-week phases (separated by a 6-week washout period) of a randomized, double-blind, crossover study, were compared in 25 hypercholesterolaemic children aged 6-18 years. Reductions in serum total cholesterol and LDL-cholesterol concentrations were highly significant in favour of the ispaghula husk-enriched cereal ($p = 0.03$ and 0.01 respectively); the reduction in LDL-cholesterol was 7% in the ispaghula husk group compared to nil in the control group [Davidson 1996]. In contrast, in a study involving 20 children aged 5-17 years with elevated serum LDL-cholesterol, who had already been on a low total fat, low saturated fat, low cholesterol diet for at least 3 months, treatment with an ispaghula husk-enriched cereal (providing 6 g of ispaghula husk per day) for 4-5 weeks had no additional lowering effect on total cholesterol or LDL-cholesterol levels [Dennison 1993].

In a randomized, double-blind, placebo-controlled study, after a low fat diet for 1 year (AHA Step 2, i.e. a diet with no more than 30% of calories from total fat, less than 7% of calories from saturated fat and less than 200 mg cholesterol daily), 105 moderately hypercholesterolaemic patients received either 5 g of colestipol (a bile acid sequestrant resin), 2.5 g of colestipol + 2.5 g of ispaghula husk, 5 g of ispaghula husk or 5 g of cellulose (as placebo) three times daily before meals for 10 weeks. The combination of colestipol + ispaghula husk reduced the ratio of total cholesterol to HDL-cholesterol significantly more than did colestipol alone or ispaghula husk alone ($p<0.05$). These findings suggested that adding ispaghula husk to half the usual dose of bile acid sequestrant resin maintains the efficacy and improves the tolerability of the resin [Spence 1995]. In another controlled study, ispaghula husk treatment significantly reduced the frequency and severity of constipation ($p<0.05$), abdominal discomfort ($p<0.01$) and heart-burn ($p<0.05$) induced by cholestyramine therapy [Maciejko 1994].

In a randomized, placebo-controlled, double-blind study, significant reductions ($p<0.01$) in serum total cholesterol (by 14.8%), LDL-cholesterol (by 20.2%) and the ratio of LDL- to HDL-cholesterol (by 14.8%) relative to baseline values were shown after 8 weeks of daily treatment with 10.2 g of ispaghula husk in 12 men with mild to moderate hypercholesterolaemia who maintained their usual diets. No significant reductions from baseline in these parameters were observed in 12 other volunteers after placebo treatment [Anderson 1988].

In a randomized, double-blind, placebo-controlled, crossover study involving 20 men with moderate hypercholesterolaemia who took 15 g of ispaghula husk daily for 40 days, a significant increase in bile acid synthesis was observed in those subjects whose LDL-cholesterol was lowered by more than 10% ($p<0.0002$), suggesting that ispaghula husk acts by stimulating bile acid synthesis [Everson 1992]. These findings are consistent with those of another randomized, double-blind, placebo-controlled, crossover study in which, besides significantly decreased serum LDL-cholesterol levels, significantly increased levels of the serum cholesterol precursors lathosterol and Δ8-cholestanol were observed after daily treatment with 10.2 g of ispaghula husk for 8 weeks ($p = 0.02$ vs. placebo), indicating increased endogenous cholesterol synthesis caused by elimination of bile acids. A trend towards decreased LDL production in response to ispaghula husk treatment was observed, suggesting that the reduction in serum LDL-cholesterol may be due to decreased LDL production [Weingand 1997].

In a randomised, double blind, placebo-controlled, multi-center study mild-moderate hypercholesterolaemic patients received 14 g/d of ispaghula husk (n=126) or placebo (microcrystalline-cellulose 14 g/d; n=128) in a low saturated fat diet for 8 weeks. Relative to placebo, ispaghula husk reduced plasma LDL by 6% ($p = 0.0002$), total cholesterol by 6.9% ($p<0.0001$), triglycerides by 21.6% ($p = 0.0004$), apolipoprotein B by 6.7% ($p<0.0001$), oxidised LDL by a mean of 6.82 U/L ($p = 0.0003$), insulin by 4.68 pmol/L ($p = 0.0218$) and systolic blood pressure by 4.0 mmHg ($p<0.0045$) after 8 weeks [Solà 2010].

The requirement that ispaghula husk should be consumed together with food for the treatment of hypercholesterolaemia has been shown in a study in which serum total cholesterol and LDL-cholesterol levels remained unchanged when ispaghula husk was taken between meals, whereas they decreased significantly when ispaghula husk was incorporated into a breakfast cereal. This suggests that the effect could be dependent on an interaction of ispaghula husk with other components of the meal [Wolever 1994b].

In a 6-week randomized, double-blind, placebo-controlled study, significant reductions in serum total cholesterol ($p = 0.03$),

LDL-cholesterol ($p = 0.01$) and triglycerides ($p = 0.005$), and a significant increase ($p<0.0001$) in HDL-cholesterol, were observed in 125 patients with type II diabetes after 6 weeks of daily treatment with 3 × 5 g of ispaghula husk [Rodriguez-Morán 1998]. The hypolipidaemic effect of ispaghula husk in patients with type II diabetes has also been shown in other studies [Frati-Munari 1989; Gupta 1994].

In a randomised, controlled, crossover study 68 hyperlipidaemic subjects (37 men, 31 postmenopausal women) consumed a test diet (high fibre diet with 2 g ispaghula husk 4 times daily) and a control low fat (25% of energy), low-cholesterol (<150 mg/d) diet. There were no differences in pretreatment values between the groups. Significant reductions in blood lipid values were seen after both diets. Mean values were significantly lower for the high fibre test diet compared to the low fat control diet for total cholesterol (2.1%; $p = 0.003$), triacylglycerols (5.2%; $p = 0.037$), apolipoprotein B (2.9%; $p<0.001$), and ratio of total cholesterol to HDL cholesterol (2.4%; $p = 0.015$) [Jenkins 2002].

In a randomised, multi-centre study 100 subjects (both sexes; 97 completed the study) with LDL >130 mg/dL and total cholesterol >220 mg/dL were treated for 12 weeks with either a combination of ispaghula husk (5.6 g twice daily) and atorvastation 10 mg once daily or atorvastation alone. After 8 weeks both groups had a significant reduction in mean LDL (20.5% for the combination group and 16% for atorvastation alone) as compared to baseline, however the difference between the groups was not significant. After 12 weeks the difference between the groups was significant ($p<0.05$), with an LDL reduction of 31.4% (compared to baseline) in the combination group compared to 22.8% in the atorvastation alone group. Serum cholesterol ($p<0.05$) and triglycerides ($p<0.05$) were significantly reduced, whereas HDL ($p<0.05$) was increased, in both groups at weeks 8 and 12; with no significant difference between the groups [Jayaram 2007].

In a prospective, open, observational study, 54 of 62 enrolled adult patients with mild to moderate hypercholesterolaemia and indications for laxative treatment completed a study protocol involving treatment with 3.5 g of ispaghula husk 3 times daily for 3 weeks. Total cholesterol significantly decreased from 252 mg/dL before treatment to 239 mg/dL after 3 weeks of treatment and LDL significantly decreased from 174 to 162 mg/dL respectively. Levels of triglycerides and HDL did not change significantly. Most of the patients reported gastrointestinal symptoms and adverse reactions in week 1, with the intensity and frequency decreasing week on week from weeks 1 to 3 [Uehleke 2008].

In a pilot clinical study 11 post-menopausal and 8 pre-menopausal women with total cholesterol >200 mg/dL were treated with 5g of ispaghula husk (baked in a cookie) 3 times daily for 6 weeks. Total cholesterol was significantly decreased in post-menopausal women (by 5.2 percent; $p< 0.05$) but not in pre-menopausal women. HDL also decreased in only the post-menopausal women (ca. 10.2%; $p<0.05$). There were no significant changes in LDL and triglycerides in either group [Ganji 2008]

Hypoglycaemic effects

A randomized, double-blind, crossover study was conducted in 18 non-insulin-dependent, type II diabetes patients, to whom 6.8 g of ispaghula husk or placebo was administered twice, immediately before breakfast and dinner (but none before lunch), during each 15-hour phase. Relative to placebo, for meals eaten immediately after ispaghula husk ingestion, postprandial maximum serum glucose elevations were reduced by 14% after breakfast and 20% after dinner; second meal effects after lunch showed a 31% reduction. Postprandial insulin concentrations measured after breakfast were reduced by 12% [Pastors 1991].

In a randomized, double-blind, placebo-controlled clinical study involving 49 patients with diabetes controlled by diet alone or diet plus glibenclamide or metformin, subjects were treated for 8 weeks with either 5.1 g ispaghula husk (n=27) or placebo (n=22) twice daily (20-30 min before breakfast and dinner) in combination with their existing drug regimen. Fasting plasma glucose (FBS) was measured every 2 weeks, plasma cholesterol, LDL, HDL, triglycerides and insulin levels every 4 weeks, HbA1c at the beginning and at the end of the study. At week 8, when compared with placebo, ispaghula husk demonstrated significantly lower levels of FBS and HbA1c ($p<0.05$) and significantly greater HDL ($p<0.05$). There were no significant changes in the levels of insulin, plasma cholesterol, LDL and triglycerides. Of the side effects recorded, flatulence was significantly higher in the placebo group ($p<0.0001$); the ispaghula husk group tolerated metformin better than placebo with significantly reduced hot flushing ($p<0.002$) [Ziai 2005].

In the second phase of an open study, 20 type II diabetic patients (12 male, 8 female) were treated for 6 weeks with 14 g of ispaghula husk per day (3.5 g before breakfast, lunch, afternoon snack and dinner) in addition to conventional dietary restrictions and standard treatment with glibenclamide. Mean serum glucose concentrations after a standard test meal were significantly lower in the ispaghula husk administration phase compared to phases 1 and 3 of the trial without ispaghula husk and only conventional dietary restrictions and standard treatment with glibenclamide. The same applied to serum total cholesterol and LDL; HDL values were unaffected by ispaghula husk supplementation [Sierra 2002].

A number of studies have shown that ispaghula husk lowers peak blood glucose levels due to delayed intestinal absorption [Kay 1978; Cummings 1978; Capani 1980; Fagerberg 1982; Florholmen 1982; Frati-Munari 1989; Abraham 1988; Wolever 1994b].

Other effects

In a 4-month randomized, double-blind, placebo-controlled, crossover study, ispaghula husk (2 × 3.5 g daily) was found to be superior to placebo ($p<0.001$) in relieving gastrointestinal symptoms, with a lower score on all of the eight scales (e.g. abdominal pain, diarrhoea, loose stools, bloating) in 36 colitis patients in remission. Less symptoms were reported in 69% of the patients while taking ispaghula husk, compared to 7% who felt better with placebo ($p<0.001$) [Hallert 1991].

A randomized, double-blind, placebo-controlled study assessed changes to the tolerability and efficacy of a 4-litre polyethylene based glycol lavage self-administered over 4 hours on the day prior to colonoscopy, following treatment for 4 days with ispaghula husk (approx 20 g per day; n=20) or placebo (n=20). Quality of preparation of the bowel was graded during colonoscopy and found to be significantly worse in the ispaghula husk group compared to placebo ($p<0.05$); tolerability was equivalent [Salwen 2004].

An open, cross-over clinical study involving 10 healthy volunteers compared the effects on gas expulsion following gas perfusion into the jejunum, after a standard diet alone and standard diet with ispaghula husk (30g/day) for seven days. Compared to standard diet alone, ispaghula husk significantly ($p<0.05$) prolonged the lag time before first gas expulsion from 1129 to 2265 seconds and significantly ($p<0.05$) reduced

the total gas evacuation volume from 1429 ml to 1022 ml, demonstrating promotion of gas retention after treatment with ispaghula husk [Gonlachanvit 2004].

In a 6-months, randomised, open clinical trial 141 hypertensive, overweight (BMI: 25-30) patients were treated with 3.5 g of ispaghula husk or guar gum 2 times daily (to be taken 20 minutes before the main 2 meals), or with standard diet alone additionally to standard hypertensive treatments which were equally distributed between the groups. After 6 months of treatment a significant improvement of both glycaemic and plasma lipid parameters in both fibre groups could be seen. Compared to baseline fasting plasma glucose decreased by 24 mg/dL ($p<0.001$), fasting plasma insulin by 5.1 µU/L ($p<0.001$), HbA1c by 0.7% ($p<0.001$), LDL by 9 mg/dL ($p<0.001$). Plasma HDL was not changed significantly in both fiber groups. Systolic blood pressure decreased by 5.2 mmHg ($p<0.001$) in the ispaghula husk group and by 5.3 mmHg in the guar group [Cicero 2007].

Pharmacokinetic properties
The vegetable fibre of ispaghula husk is resistant to digestion in the upper intestinal tract and thus is not absorbed. Subsequent degradation of the fibre by colonic bacteria results in the production of gas and short chain fatty acids. Studies in animals have demonstrated at least partial absorption of short chain fatty acids [Kay 1978; Cummings 1981; Brunton 1990].

Preclinical safety data
Not relevant.

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

PRIMULAE RADIX

2021

Primula root

DEFINITION

Primula root consists of the whole or cut, dried rhizome and root of *Primula veris* L. or *P. elatior* Hill.

The material complies with the monograph of the European Pharmacopoeia [European Pharmacopoeia].

CONSTITUENTS

Triterpene saponins of the oleanane-type usually in the range of 3-10 %. Saponins from *Primula elatior* (such as primulasaponin) are derived from the aglycone protoprimulagenin A, which is converted to primulagenin A. The main saponins of *Primula veris* are primacrosaponin and priverosaponin B, derived from anagalligenin, priverogenin B and priverogenin B-22-acetate respectively [Tschesche 1968,1975,1977,1983; Jentzsch 1973; Grecu 1975; Glasl 1984; Wagner 1986; Çalis 1992; Siems 1998; Hahn-Deinstrop 2000; Müller 2006; Schilcher 2010; Volk 2016; Apel 2017; Schöpke 2019; Włodarczyk 2020].

The phenolic glycosides primverin and primulaverin occur in both species, in amounts up to 2.3 %; they are the 2-primeverosides of 4-methoxy- and 5-methoxysalicylic acid methyl esters respectively [Wagner 1986; Thieme 1971; Müller 2006; Volk 2016; Bądczek 2017; Schöpke 2019]. These substances change during the drying process into the respective aglycones which are responsible for the characterictic odour of the roots [Schilcher 2010; Schöpke 2019].

CLINICAL PARTICULARS

Therapeutic Indications

Cough associated with common cold [Antonone 1988; Volk 2016; Schöpke 2019].

In this indication, the efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adult daily dose: 0.5-1.5 g of the drug as a decoction or equivalent preparation, taken in small amounts 3 times daily [Antonone 1988; Schilcher 2010; Volk 2016].
Elderly: dose as for adults.
Children: 4-10 years, 0.5-1.0 g daily; 10-16 years, 0.5-1.5 g daily [Dorsch 1993].

Method of administration
For oral administration.

Duration of administration
No restriction.

Contra-indications
Known hypersensitivity to primula or its constituents [Schilcher 2010; Volk 2016].

Special warnings and special precautions for use
Caution is recommended in patients with gastritis or gastric ulcer.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy or lactation without medical advice.

E/S/C/O/P
MONOGRAPHS

Effects on ability to drive and use machines
None known.

Undesirable effects
In rare cases gastrointestinal disturbance may occur [Schilcher 2010; Schöpke 2019]

Overdose
Overdosage may lead to stomach upset, vomiting or diarrhoea [Schöpke 2019].

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties
Primula root has an expectorant action arising primarily from local irritation of the gastric mucosa by saponins; this provokes a reflex increase in bronchial secretions, which dilutes the mucus and reduces its viscosity [Boyd 1954; Schilcher 2010; Schöpke 2019]. Irritation of mucous membranes in the throat and respiratory tract by saponins may also cause an increase in bronchial secretions and the surface tension-lowering action of saponins might help to reduce the viscosity of sputum, making it easier to eject [Hostettmann 1995].

In vitro experiments

Antimicrobial activity
Primula root saponins inhibit the growth of a variety of bacteria and fungi [Tschesche 1965; Wolters 1966]. An unspecified saponin mixture from *Primula veris* exhibited activity against influenza (A_2/Japan 305) virus, producing 89% inhibition at a concentration of 6.2 µg/mL [Rao 1974; Büechi 1996].

Other effects
A hexane extract (50 µg/mL) of *Primula veris* root inhibited COX-1 and COX-2 by 54% and 66% respectively [Lohmann 2000].

A tincture (1:5; ethanol 50% V/V) at concentrations between 0.1% and 1% dose-dependently inhibited the LPS-induced release of IL-8 in primary human monocytes [Nauert 2005b].

In vivo experiments
An undefined mixture of saponins from primula root at a concentration of 1:10,000 increased the ciliary activity of throat epithelium of curarized frog. This effect was assumed to be due to a decrease in surface tension of the mucus. The ciliary activity was less at a concentration of 1:6,000 and ceased at 1:3,000 due to toxic effects [Vogel 1963].

Saponins from *P. officinalis* (syn. *veris*) inhibited pain provoked by compression of inflamed paws of rats (n=16) at doses of 2.5 mg/kg p.o. (29.2 % inhibition; $p<0.02$) and 1.25 mg/kg i.v. (27.7 % inhibition; $p<0.001$) [Cebo 1976].

Pharmacological studies in humans
None.

Clinical studies
In a non-controlled study in patients (adults and children) with antibiotic-resistant stomatitis caused by *Candida albicans*, the topical application of an aqueous solution of saponins from *P. vulgaris* led to the disappearance of local symptoms within 2-3 days in more than 100 cases [Margineanu 1976].

Pharmacokinetic properties
No specific data are available on the pharmacokinetics of primula root saponins. In general, saponins are poorly absorbed by the body [Hostettmann 1995].

Preclinical safety data
The oral toxicity of saponins in mammals is relatively low due to their poor absorption from the gastrointestinal tract [Hostettmann 1995]. The LD_{50} for the saponin fraction from *P. veris* in mice was determined as 10.5 – 56 mg/kg b.w. after i.p. application and for primulic acid (mixture of saponins) in rats as 1.2 mg/kg b.w. after i.v. application [Vogel 1963; Grecu 1975; Cebo 1976; Schöpke 2019].

No signs of toxicity were found after oral administration of saponins to rats. Local irritating effects have been observed on the rabbit cornea [Vogel 1963; Schöpke 2019].

Clinical safety data
In various observational studies, a combination containing 5% thyme liquid extract and 2.5% primula root liquid extract (1:2-2.5; ethanol 70% m/m) was administered to children. In three studies involving 636, 330 and 839 children from 1-12 years of age, six adverse reactions (pruritus, itching, exanthema) occurred, while in another study involving 200 children between 6 and 12 months of age, one case of perioral oedema and one case of vomiting occurred [Nauert 2003, 2005a, 2006; Schmidt 2008].

In a randomized, double-blind, placebo-controlled, multicenter, prospective study, a combination containing 40% thyme liquid extract and 20% primula root tincture (1:5; ethanol 50% V/V) was administered to 150 patients (97 women, 53 men) suffering from acute bronchitis at a daily dose of 5 x 30 drops. The tolerability was good in both verum and placebo groups; neither serious adverse events nor clinically relevant findings in the safety parameters were observed. A total of 7 adverse events occurred, 2 in the verum group (slight gastrointestinal complaints) and 5 in the placebo group. One of the two adverse events in the verum group was considered to be possibly related to the intake of the study medication. In the global safety assessment, the tolerability of both medications was rated as “good” or “very good” by more than 90% of the patients and physicians [Gruenwald 2005].

In a randomized, single-blind, bi-centric, prospective study, a combination containing 5% thyme liquid extract and 2.5% primula root liquid extract (1:2-2.5; ethanol 70% m/m), as well as a combination containing 40% thyme liquid extract and 20% primula root tincture (1:5; ethanol 50% V/V), were given to 189 patients (121 women, 68 men) suffering from acute bronchitis over a time period of 7-9 days at a daily dose of either 6 x 5 mL of the first or 5 x 1 mL of the second test medication. The tolerability was very good in both groups; neither serious adverse events nor clinically relevant findings in the safety parameters were observed. A total of 10 adverse events (mild gastrointestinal complaints, headache) occurred, of which 5 were considered to be possibly or probably related to the intake of the study medication. In the global safety assessment, the tolerability of both medications was rated by about 90% of the patients and physicians as "good" or "very good" [Gruenwald 2006].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

PRUNI AFRICANAE CORTEX 2020

Pygeum africanum bark

DEFINITION

Pygeum africanum bark consists of the whole or fragmented, dried bark of the stems and branches of *Prunus africana* (Hook f.) Kalkman (synonym: *Pygeum africanum* Hook.f.).

The material complies with the European Pharmacopoeia [Pygeum africanum bark].

CONSTITUENTS

The main characteristic consistuents are phytosterols (approx. 0.05 %) e.g. ß-sitosterol and its glucoside, ß-sitostenone, free fatty acids (C_{12} - C_{24}), pentacyclic triterpenic acids (ursolic and oleanolic acid derivatives), long chain aliphatic alcohols (*n*-docosanol and *n*-tetracosanol and their ferulic acid esters), atranorin and atraric acid (methyl 2,4-dihydroxy-3,6-dimethylbenzoate) [Longo 1981, 1983; Pierini 1982; Martinelli 1986; Bruneton 2009; Fourneau 1996; Bombardelli 1997; Liersch 2002; Schleich 2006a, 2006b; Nyamai 2015; Thompson 2019].

CLINICAL PARTICULARS

Therapeutic indications

Symptomatic treatment of micturition disorders (dysuria, pollakiuria, nocturia, urine retention) in benign prostatic hyperplasia (BPH) [Andro 1995; Bombardelli 1997; Wilt 1998; Ishani 2000; McQueen 2001] at stages I and II as defined by Alken [Alken 1973] or stages II and III as defined by Vahlensieck [Vahlensieck 1996].

Stages of Benign Prostatic Hyperplasia as defined by Alken [Alken 1973]	Stages of Benign Prostatic Hyperplasia as defined by Vahlensieck [V.1996]
Stage I Dysuria, pollakiuria, possibly nocturia, reduction in projection of the urine flow, no residual urine (stage of compensation of the bladder musculature).	**Stage I** No micturition problems More or less marked BPH Urine flow: greater than 15 mL/s maximal flow No residual urine No bladder trabeculation
Stage II Same symptoms as at stage I, but additionally residual urine (incipient decompensation of the bladder musculature).	**Stage II** Intermittent micturition problems (frequency, calibre of urine flow) More or less marked BPH Urine flow: between 10 and 15 mL/s maximal flow No or low (≤50 mL) residual urine No or incipient bladder trabeculation
Stage III Complete stoppage or overflow of the bladder (decompensation of the bladder musculature).	**Stage III** Permanent micturition problems (frequency, calibre of urine flow) More or less marked BPH Urine flow: less than 10 mL/s maximal flow Residual urine more than 50 mL Trabeculated bladder
	Stage IV Permanent micturition problems (frequency, calibre of urine flow) More or less marked BPH Urine flow: less than 10 mL/s maximal flow Residual urine more than 100 mL Overflowing bladder Stoppage of the upper urinary tract

E/S/C/O/P MONOGRAPHS

Posology and method of administration

Dosage

Daily dose: 100-200 mg of lipophilic extract [Andro 1995; Bombardelli 1997; Ishani 2000; McQueen 2001; Descazeaud 2015].

Method of administration
For oral administration.

Duration of administration
No restriction. Long-term administration may be advisable. If symptoms persist or worsen, medical advice should be sought.

Contra-indications
None known.

Special warnings and special precautions for use
All cases of difficulty in micturition require clarification by a physician and regular medical checks in order to rule out the need for other treatment, e.g. surgical intervention. Consultation with a physician is particularly necessary in cases of blood in the urine or acute urine retention.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
Not applicable.

Effects on ability to drive and use machines
None known.

Undesirable effects
In rare cases, mild gastrointestinal disturbances may occur [Ishani 2000; Andro 1995; Bombardelli 1997; McQueen 2001].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Most of the pharmacological and clinical studies have been performed with a chloroform extract containing 14% sterols.

Pharmacodynamic properties

The aetiology of BPH involves initially the microscopic growth of the prostate and its progression to a macroscopic enlargement of the gland. In the second phase, progression to clinical BPH, the patient develops symptomatic dysuria. About half of men with macroscopic BPH suffer from micturition complaints.

Although macroscopic growth of the prostate is a condition for the development of complaints, enlargement is not, by itself, sufficient for the progression to clinical BPH. Particularly in the case of irritative symptoms, additional factors such as prostatitis, vascular infarct or tensile strength of the glandular capsule are involved [Isaacs 1989; Sökeland 2000].

So far, the aetiology of this age-dependent disease is not completely understood. Various mechanisms have been postulated to be causally connected with prostatic growth:

- A shift in prostatic androgen metabolism due to an increase in 5α-reductase activity, which leads to an abnormal accumulation of dihydrotestosterone (DHT) [Lichius 2000; Carson 2003; Nahrstedt 1993; Miersch 1993].
- An increase in the oestrogen/androgen ratio and increased synthesis of sex hormone binding globulin (SHBG) [Farnsworth 1999; Miersch 1993].
- Growth factors, changes in prostatic stromal-epithelial interaction (embryonic reawakening) and/or an increase in prostatic stem cells [Lichius 2000; Isaacs 1989; Lawson 1990; Sökelandt 2000].
- An imbalance between cell proliferation and cell death (reduced apoptosis) [Carson 2003; Sökelandt 2000].
- Increased production of prolactin and elevated levels of prostaglandins and leukotrienes [Farnsworth 1999; Nahrstedt 1993; Miersch 1993].

A review of *in vitro* and *in vivo* pharmacological studies identifies various mechanisms of action of pygeum bark including [Edgar 2007]:

- Prostate hyperplasia via b-FGF (basic fibroblast growth factor), EGF (epidermal growth factor) and androgen-mediated cell proliferation.
- Bladder function with improvement in contractile dysfunction mediated via myosin isoform expression, lessened synaptic denervation and improved mitochondrial function.

In vitro experiments

Hormonal activity
A lipophilic extract (200:1, methylene chloride; standardized to 13% sterols) concentration-dependently inhibited the activity of 5α-reductase from rat prostate cells (IC_{50} 0.78 mg/mL) and of aromatase from human placenta cells (IC_{50} 0.98 mg/mL) [Hartmann 1996].

However, an earlier study demonstrated that a lipophilic extract had only a slight inhibitory activity (IC_{50} 63 µg/mL) against 5α-reductase from the human prostate in comparison with the synthetic 5α-reductase inhibitor finasteride IC_{50} 1ng/mL) [Rhodes 1993].

A dichloromethane extract showed an antiandrogenic activity in the luciferase assay (inhibition of hormone-activated human androgen receptor) at a concentration of 600 µg/mL. A bio-guided fractionation resulted in the isolation of atraric acid [Schleich 2006a, 2006b].

Atraric acid (10µM) inhibited both the hormone-activated human androgen receptor (AR) and the growth of AR expressing human prostate cancer cell lines LNCaP and C4-2 [Papaionnou 2008].

Anti-inflammatory activity
A lipophilic extract significantly inhibited the synthesis of 5-lipoxygenase metabolites in human polymorphonuclear cells stimulated with the calcium ionophore A23187: 5-HETE ($p<0.001$ at 1 µg/mL), LTB_4 ($p<0.01$ at 3 µg/mL), 20-hydroxy-LTB_4 ($p<0.001$ at 3 µg/mL) and 20-carboxy-LTB_4 ($p<0.01$ at 3 µg/mL) [Paubert-Braquet 1994a].

Antiproliferative effects
Growth factors seem to play a role in the pathogenesis of BPH, in particular b-FGF, which is present at an elevated level in BPH tissue. It has been shown that b-FGF, EGF and DHT stimulate the growth of fibroblasts from the adult prostate [Bombardelli 1997].

A lipophilic extract at 1µg/mL significantly ($p<0.05$) inhibited proliferation of mouse 3T3 fibroblasts stimulated by b-FGF and EGF [Paubert-Braquet 1994b].

The activity of a lipophilic extract on DNA synthesis was investigated by measuring the [^{3}H] thymidine incorporation into rat prostatic stromal cells. The extract inhibited the proliferation of both non-stimulated cells (IC_{50}: 14.4 µg/mL) and cells stimulated by the mitogenic growth factors EGF, insulin-like growth factor-I and b-FGF (IC_{50} values of 4.6, 7.7 and 12.6 µg/mL respectively) at similar concentrations to genistein, a known growth inhibitor in mitogenic studies. The proliferation induced by TPA (12-O-tetradecanoylphorbol-13-actate) and PDBu (phorbol-12,13-dibutyrate), direct activators of protein kinase C (PKC), was also concentration-dependently inhibited with IC_{50} values of 12.4 and 8.1 µg/mL respectively, compared to an IC_{50} of approx. 1nM for the PKC inhibitor staurosporine [Yablonsky 1997].

A lipophilic extract (5 – 100 µg/mL) dose-dependently inhibited proliferation of human prostatic fibroblasts and myofibroblasts stimulated by b-FGF and EGF [Boulbes 2006].

A 30% ethanolic extract inhibited the growth of PC-3 and LNCaP cells (IC_{50} 2.5 µl/mL for both cell lines). The extract significantly ($p<0.05$) induced apoptosis at 2.5 µl/mL in both cell lines and displaced bound estradiol (>70% at 5 µl/mL) and bound DHT (>60% at 5 µl/mL) in a competitive ligand-binding assay [Shenouda 2007].

Primary prostate stromal cells taken from patients both with and without BPH/LUTS (lower urinary tract symptoms) were treated with a lipophilic extract. Antiproliferative potency and extract-induced apoptosis were increased in the BPH versus the non-BPH stromal cells [Quiles 2010].

An ethanolic extract blocked the expression of IL-7 mRNA at 50 µg/mL and showed low cytotoxicity in the IEC-6 proliferation test (IC_{50} > 200 µg/mL) [Mwitari 2013].

Antioxidant effects
A chloroform extract was fractionated by partitioning between solvents of varying polarity and by column chromatography. The inhibitory activity of the extract and fractions from it on ferrous ion-induced stimulation of lipid peroxidation in microsomal preparations from rabbit livers was evaluated. The extract and fractions containing high levels of myristic acid and markedly inhibited lipid peroxidation with a potency comparable to that of α-tocopherol [Hass 1999].

Antibacterial activity
Methanolic extracts showed antibacterial activity in the diffusion method against *Salmonella typhi*, *Proteus vulgaris*, *Serratia marcescens*, *Escherichia coli*, *Bacillus cereus* [Ngule 2014], *Staphylococcus aureus* and methicillin-resistant *Staphylococcus aureus* [Mwitari 2013].

Other effects
A dichloromethane-methanol extract inhibited the proliferation of various cancer cell lines in the resazurin assay with IC_{50} values from 30 to 35 µg/mL [Ochwang'I 2018].

In vivo experiments

Effects on the prostate
Intragastric administration of a lipophilic extract to rats at 2 mg/kg b.w. daily for 20-50 days stimulated the secretory activity of the prostate in normal rats and prevented the development of prostatic hyperplasia induced by injection of human prostate adenoma tissue [Thieblot 1971]. Intraperitoneal administration of the extract at 1 and 10 mg/kg b.w. daily for 20 days enhanced secretory activity of the prostate and seminal vesicles in castrated rats. However, the activity of testosterone on these glands was antagonized, as shown by a significant reduction in weight gain of these organs ($p<0.05$). On the other hand, in castrated and adrenalectomised rats the extract potentiated the activity of testosterone on the target organs and increased the content of pituitary gonadotrophins [Thieblot 1977].

Intragastric administration of the extract to rats at 100 mg/kg b.w. daily for 3 days also increased prostate secretions [Clavert 1986].

A 30% ethanolic extract was administered to TRAMP mice (transgenic adenocarcinoma of the mouse prostate model) for 5 months (as 0.128 g/kg of the diet). The treated group showed a significant reduction ($p=0.034$) in well-differentiated prostate carcinoma (35%) compared to control (62.5%). There was no significant effect on total body weight, reproductive tract weight, testes or prostate weight [Shenouda 2007].

Effects on bladder function
Administration of a lipophilic extract to rats reduced the response of the bladder to electrical stimulation, phenylephrine, adenosine triphosphate and carbachol. The extract also reduced the bladder hyper-reactivity to carbachol in guinea pigs [Andro 1995].

After intragastric pre-treatment of rabbits with a lipophilic extract at 1, 10 and 100 mg/kg b.w. daily for 3 weeks, and further treatment for 2 weeks combined with partial bladder outlet obstruction, the bladders were excised, weighed and *in vitro* contraction studies were performed. The extract had no effect on bladder mass, but there was significant, dose-dependent preservation of the contractile responses of bladder strips ($p<0.05$).

In a further experiment (intragastric pre-treatment of rabbits at 100 mg/kg b.w. daily for 3 weeks; partial urethral obstruction for 1-14 days) the extract had no effect on bladder weight but reduced on day 1 and prevented from day 3 the severity of contractile dysfunctions associated with partial outlet obstruction. Pre-treatment restored the activities of citrate synthase and calcium-ATPase to nearly normal from day 7 onwards after an initial significant ($p<0.05$) reduction of their activities.

In another study, after 2 weeks of mild or severe partial outlet obstruction, the extract was intragastrically administered to rabbits at 100 mg/kg/day for 3 weeks. In contrast to the previous experiments, the rabbit bladder weight of the verum group with severe outlet obstruction was lower than in the placebo group but still significantly ($p<0.01$) higher than in the control group. Contractile dysfunction and reduction in compliance were reversed in the mild outlet obstruction group, while in the severe outlet obstruction group contractile dysfunction was improved [Levin 1996a; Levin 1996b; Levin 1997; Levin 2000].

In a subsequent study, rabbits received the extract intragastrically (100 mg/kg/day for 3 weeks) after 2 weeks of partial outlet obstruction. Partial obstruction resulted in a significant increase in bladder weight compared to that of unobstructed animals (8.8 g versus 2.3 g; $p<0.05$). Obstructed rabbits in the verum group had significantly lower bladder weights than placebo (4.2 g versus 8.8 g; $p<0.05$). The diminished contractile response to field stimulation and carbachol was restored to normal. Relative ratios for myosin heavy chain isoforms, altered at mRNA and protein levels by the obstruction, returned nearly to normal in the group treated with the extract ($p>0.01$) [Gomes 2000].

In a related study, intragastric administration of the extract to rabbits (30 mg/kg/day for 3 weeks) after 2 weeks of partial outlet obstruction resulted in reduced bladder hypertrophy, improved contractile responses and reversal of the induced structural

damage to cellular and subcellular membranes [Levin 2002]. Intragastric pre-treatment of rabbits at 3 mg/kg/day for 3 weeks protected the bladder from contractile dysfunctions induced by bilateral ischemia followed by reperfusion [Levin 2005].

In a 7-week experiment, partial urethral obstruction was created in rats by stimulating prostate growth with DHT, administered subcutaneously at 1.25 mg/kg b.w. during weeks 3 and 4. Intragastric administration of a lipophilic extract (100 mg/kg/day for 2 weeks before, 2 weeks during and 3 weeks after DHT treatment) significantly ($p<0.05$) reduced micturition frequency and normalized urethral opening pressure, voiding volume, as well as the weight of the total prostate and of the ventral lobe, compared to controls [Choo 2000]. A subsequent 6-week study in rats, during which DHT was administered in weeks 1 and 2, showed that co-treatment or post-treatment with the extract at 100 mg/kg/day suppressed the effects on micturition frequency and volume, but that only co-treatment could correct a developing increase in prostatic weight ($p<0.05$) [Yoshimura 2003].

A chloroform extract (100 mg/kg/day p.o. for 8 weeks) significantly ($p<0.05$) reduced the enhanced levels of hydroxyproline, transforming growth factor β1 and basic fibroblast growth factor in the bladder of streptozotocin-induced diabetic rats [Yongzhi 2008].

In an 8-week experiment streptozotocin-induced diabetic rats were fed with a chloroform extract (100 mg/kg/day). Catalase and SOD activities significantly ($p<0.05$) increased and MDA levels significantly ($p<0.05$) decreased in the treated group, compared to control. The number of iNOS-positive cells and the maximal bladder volume significantly ($p<0.05$) decreased, while bladder pressure and maximal bladder pressure significantly ($p<0.05$) increased in the treated group [Wang 2010].

Anti-inflammatory effects
A lipophilic extract, administered intragastrically at 400 mg/kg b.w., markedly reduced the carrageenan-induced paw oedema in rats. When administered intraperitoneally at 10 and 100 mg/kg the extract inhibited the increased vascular permeability caused by histamine [Marcoli 1986].

Pharmacological studies in humans
A histological study of prostate biopsy samples taken from 20 patients with BHP, following oral administration of a lipophilic extract at 100 mg/day or placebo for 20 days, revealed an improvement in capillary perfusion and fewer signs of inflammation in the verum group [Bongi 1972].

Another histological study of prostate biopsies ($n = 6$) taken before and after treatment with a lipophilic extract (75 mg/day for 1-3 months) indicated an improvement in secretory activity of the prostate without modifying its size [Dorémieux 1973].

In 22 men with insufficient prostatic secretion (reduced acid phosphatase activity) a lipophilic extract (150 mg/day for 3 months) significantly ($p<0.05$) increased prostatic secretion (increase in acid phosphatase and total protein concentration) [Clavert 1986].

In a study involving 18 men suffering from pollakiuria, dysuria and nocturia, a lipophilic extract (150 mg/day for 15-20 days) significantly reduced the volume of hypertrophic prostate ($p<0.01$) [Mathé 1995].

Serum collected from a 46 year old man without clinical BPH, after oral intake of a chloroform extract at 100 mg daily for 5 days, induced significant decreases in the proliferation of primary fibromuscular prostatic cells ($p<0.001$), organotypic fibromuscular prostatic cells ($p<0.001$) and WPMY cells ($p<0.05$). The transcriptome analysis revealed an upregulation of genes involved in multiple tumour suppression pathways and a downregulation of genes involved in inflammation and oxidative-stress pathways [Larré 2012].

Clinical studies
A systematic review of randomized controlled studies with lipophilic extract assessed 18 studies involving 1562 men with symptomatic BPH; 17 studies were double-blinded but only 1 reported a method of treatment allocation concealment. The mean study duration was 64 days and the daily dose of extract ranged from 75 to 200 mg. Data from 6 placebo-controlled studies involving 474 participants were suitable for pooling to provide a weighted estimate of effectiveness and meta-analysis indicated moderate improvement in the combined outcome of urologic symptoms and flow measures; nocturia decreased by 19% and residual urine volume by 24%; peak urine flow increased by 23%. Although the duration of the studies was short and the study design and types of reported outcome varied greatly, it was concluded that pygeum bark modestly, but significantly ($p<0.001$ to $p<0.05$), improves urologic symptoms and flow measures [Ishani 2000].

Other clinical reviews, which assessed open as well as controlled studies, involved a total of 1310 patients, daily doses of 75-200 mg of lipophilic extracts and treatment periods ranging from 15 to 120 days. They all concluded that pygeum bark improved the symptoms and objective measures of BPH and was well tolerated [Andro 1995; Bombardelli 1997; McQueen 2001].

The following results were obtained in randomized, double-blind, placebo-controlled studies with lipophilic extracts:

- 50 BPH patients treated with 75 mg of extract or placebo daily for 60 days: significant improvements in nocturnal micturition frequency ($p<0.01$), dysuria ($p<0.05$) and volume of residual urine ($p<0.01$) in the verum group [Bongi 1972].

- 120 BPH patients treated with 100 mg of extract or placebo daily for 6 weeks: significant ($p<0.01$) improvement in nocturnal micturition frequency, difficulty in starting micturition and sensation of incomplete voiding of the bladder in the verum group [Dufour 1984].

- 40 BPH patients treated with 200 mg of extract or placebo daily for 60 days: significant improvements in micturition frequency ($p<0.05$), nocturia ($p<0.01$), dysuria ($p<0.01$) and maximum and mean urine flow ($p<0.05$) in the verum group [Rizzo 1985].

- 263 BPH patients at Alken stage I treated with 100 mg of extract or placebo daily for 60 days: significant improvements in nocturia ($p = 0.007$), peak urine flow ($p = 0.002$), residual volume ($p = 0.02$) and overall symptoms ($p = 0.001$) in the verum group [Barlet 1990].

- 40 BPH patients treated with 100 mg of extract or placebo daily for 60 days: significant improvements in micturition frequency ($p<0.001$), urgency ($p<0.02$), dysuria ($p<0.02$) and peak urine flow ($p<0.05$) in the verum group [Bassi 1987].

Two different daily dosage regimens for a lipophilic extract were compared in a randomized study. Out of 235 BPH patients on commencement, 209 completed a 2-month double-blind phase, receiving either 50 mg of the extract twice daily (group A, 101

patients) or 100 mg once daily in the evening (group B, 108 patients). The primary efficacy parameter was the International Prostate Symptom Score (IPSS), a 40% or greater reduction from baseline being considered a significant improvement. Both treatments had similar efficacy after 2 months: in group A the IPSS decreased by 38%, the quality of life score improved by 28% and the maximum urinary flow rate increased by 16%; in group B the figures were 35%, 28% and 19%. In a subsequent 10-month open phase 174 patients took 100 mg of the extract once daily. After 12 months the overall IPSS had decreased by 46% and the maximum urinary flow rate had increased by 15% [Chatelain 1999].

In a comparison with a pollen extract, 38 BPH patients at Alken stages I and II received 100 mg of a lipophilic extract daily for 4 months. From evaluation of urodynamic and ultrasonographic parameters and subjective assessment, improvements compared to baseline were evident in peak flow rate (+11%), residual urine volume (-22%), obstructive symptom score (-46%) and irritative symptom score (-40%) [Dutkiewicz 1996].

A TRIUMPH (Trans European Research Into the Use of Management Policies for LUTS suggestive of BPH in Primary Healthcare) study recorded the treatment and outcomes of 2351 LUTS/BPH patients in 6 European countries over a 1-year follow-up period. Pygeum bark, administered to 90 of the patients, gave a mean reduction of 3.4 IPSS points. Clinically significant improvements (IPSS reduction >4) were seen in 43% of the patients [Hutchison 2007].

Pharmacokinetic properties
No data available.

Preclinical safety data

Acute toxicity
A single dose of the lipophilic extract up to 8 g/kg b.w. administered intragastrically to mice and rats was well tolerated [Andro 1995].

Neither mortality nor signs of adverse effects were observed after oral administration of single doses of the lipophilic extract to mice at 1-6 g/kg b.w. and to rats at 1-8 g/kg b.w. [Bombardelli 1997].

Repeated dose and chronic toxicity
Short-term (1 month) and long-term (6 months) intragastric administration of the extract to dogs at 375 mg/kg/day and to rats at 750 mg/kg/day caused no adverse effects to haematologic, biochemical or anatomical/pathological parameters [Andro 1995].

No adverse reactions were observed after daily intragastric administration of the extract to mice at 60 mg/kg or rats at 600 mg/kg for 11 months [Bombardelli 1997].

Oral administration of the extract to rats at up to 1 g/kg b.w. daily for 8 weeks did not cause clinical or pathological signs of toxicity, but moderate rises were observed in serum ALAT and blood urea nitrogen levels. At 3.3 g/kg daily for 6 days the extract caused marked clinical signs of toxicity, organ damage and a 50% mortality rate; the main lesions were hepatocellular degeneration and necrosis, diffuse nephrosis and myocardial degeneration. These findings confirmed the safety of the extract at therapeutic dosages, since signs of toxicity were observed only at very high doses [Gathumbi 2000&2002].

Reproductive toxicity
At up to 80 mg/kg/day the extract had no effect on fertility in male rats or rabbits [Andro 1995].

Carcinogenicity
In vivo and in vitro mutagenicity studies on the extract indicated a complete absence of mutagenic or clastogenic potential [Andro 1995].

Clinical safety data
The use of Pygeum africanum bark is considered to be well tolerated [Descazeaud 2015]. A number of controlled and uncontrolled clinical studies involving 2872 patients provided information on specific adverse events. Adverse events due to Pygeum africanum bark were generally mild in nature and similar in frequency to placebo. The most common complaint was mild gastrointestinal upset [Ishani 2000; Andro 1995; Bombardelli 1997; McQueen 2001].

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

PSYLLII SEMEN

Psyllium Seed

2017

DEFINITION

Psyllium seed consists of the ripe, whole, dry seeds of *Plantago afra* L. (*Plantago psyllium* L.) or *Plantago indica* L. (*Plantago arenaria* Waldstein and Kitaibel).

The material complies with the monograph of the European Pharmacopoeia [Psyllium seed].

CONSTITUENTS

Mucilage polysaccharide (10-15%) [Karawya 1971a; Bräutigam 2007] in the epidermis, consisting of xylose, galacturonic acid, arabinose and rhamnose residues [Karawya 1971a]. The seeds also contain protein (15-20%), fixed oil (5-13%) [Sticher 2015], the trisaccharide planteose [Sticher 2015; Balbaa 1971] and small amounts of phytosterols, triterpenes [Sticher 2015; Balbaa 1971], the iridoid glucoside aucubin and alkaloids (plantagonine, indicaine and indicamine) [Sticher 2015; Balbaa 1971; Karawya 1971b], but no starch [Karawya 1971a; Bräutigam 2007].

CLINICAL PARTICULARS

Therapeutic indications

Treatment of occasional constipation [Brunton 1996; Kay 1978].
Conditions in which easy defecation with soft stools is desirable, e.g. in cases of anal fissures or haemorrhoids, after rectal or anal surgery, and during pregnancy [Bräutigam 2007; Wichtl 2009; USP Dispensing Information 1994].
Adjuvant symptomatic therapy in cases of diarrhoea from various causes [Brunton 1996].

Posology and method of administration

Dosage
Adults and children over 12 years of age: as a laxative, 10-30 g daily of the seeds [Bräutigam 2007; Wichtl 2009] or equivalent preparations; in cases of diarrhoea, up to 40 g daily [Bräutigam 2007] divided into 2-3 doses.
Children 6-12 years: as a laxative, half the adult dose [Dorsch 2002].

Method of administration
For oral administration.

It is very important to take the seeds with a large amount of liquid, e.g. mix approx. 5 g with 150 ml of cool water, stir briskly and swallow as quickly as possible, then maintain adequate fluid intake.

Psyllium seed should preferably be taken at mealtimes; it should not be taken immediately prior to going to bed. Any other medications should be taken at least 30-60 minutes before psyllium seed in order to avoid delayed absorption.

Duration of administration
In cases of diarrhoea, medical advice should be sought if the symptoms persist for more than 3 days in order to ensure definitive diagnosis of the cause.

Contra-indications

Children under 6 years of age.
Known hypersensitivity to psyllium seed [Brayfield 2014].

Psyllium seed should not be used by patients with the following conditions unless advised by a physician: faecal impaction; undiagnosed abdominal symptoms; a sudden change in bowel habit that persists for more than 2 weeks; rectal bleeding; failure to defecate following the use of a laxative; abnormal constrictions in the gastrointestinal tract; potential or existing intestinal obstruction (ileus); diseases of the oesophagus and cardia; megacolon [Bräutigam 2007, Brunton 1996];

E/S/C/O/P
MONOGRAPHS

diabetes mellitus which is difficult to regulate [Bräutigam 2007, Brunton 1996, Kay 1978].

Special warnings and special precautions for use
A sufficient amount of liquid should always be taken: at least 150 ml of water per 5 g of seed [Brayfield 2014].

Taking psyllium seed without adequate fluid may cause it to swell and block the throat or oesophagus and may cause choking. Intestinal obstruction may occur should adequate fluid intake not be maintained. Do not take psyllium seed if you have ever had difficulty in swallowing or have any throat problems. If you experience chest pain, vomiting, or difficulty in swallowing or breathing after taking it, seek immediate medical attention. Treatment of the elderly and debilitated patients requires medical supervision. Administration to the elderly should be supervised.

In cases of diarrhoea sufficient intake of water and electrolytes is important.

Interaction with other medicaments and other forms of interaction
Enteral absorption of concomitantly administered minerals (e.g. calcium, iron, lithium, zinc), vitamins (B12), cardiac glycosides and coumarin derivatives may be delayed [Bräutigam 2007; USP Dispensing Information 1994; Brunton 1996; Drews 1979; Cummings 1978]. For this reason, other medications should be taken at least 30-60 minutes before psyllium seed. In the case of insulin-dependent diabetics it may be necessary to reduce the insulin dose [Cummings 1978; Kay 1978].

Pregnancy and lactation
The product can be used during pregnancy and lactation [Lewis 1985].
A risk is not to be expected since the constituents of psyllium seed are not absorbed and have no systemic effects.

Effects on ability to drive and use machines
None known.

Undesirable effects
Flatulence may occur, but generally disappears during the course of treatment.
Abdominal distension and risk of oesophageal or intestinal obstruction and faecal impaction may occur, particularly if psyllium seed is ingested with insufficient fluid.

There is a risk of allergic reaction from inhalation of the powder during occupational exposure. Due to the allergic potential of psyllium seed, patients must be aware of reactions of hypersensitivity including anaphylactic reactions in single cases [Brayfield 2014].

Overdose
Overdosage may cause abdominal discomfort and flatulence, or even intestinal obstruction. Adequate fluid intake should be maintained and management should be symptomatic.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

Laxative effects
Psyllium seed increases the volume of intestinal contents by the binding of fluid, resulting in increased faecal weights. This leads to physical stimulation of the gut [Bräutigam 2007; Brunton 1996].

Psyllium seed increases stool weight and water content due to the fibre residue, the water bound to that residue [Bräutigam 2007; Brunton 1996] and the increased faecal bacterial mass [Brunton 1996].

Antidiarrhoeal effects
In cases of diarrhoea, psyllium seed binds fluids and thus increases the viscosity of intestinal contents [Brunton 1996], thereby normalizing transit time and frequency of defecation [Bräutigam 2007].

Pharmacokinetic properties
The vegetable fibre of psyllium seed is resistant to digestion in the upper intestinal tract; thus it is not absorbed. Part of the fibre is degraded by colonic bacteria [Bräutigam 2007; Kay 1978].

Preclinical safety data
After 125 days on a diet containing 25% of psyllium seed, albino rats showed a dark pigmentation of the suprarenal gland, the kidney marrow and the liver. Dogs showed a grey colour of the kidneys after being fed a diet containing 25% of psyllium seed for 30 days. Similar effects have not been observed in humans. The pigment probably originates from the black pericarp of *Plantago afra*. When the seeds were extracted with hot water prior to feeding and then fed to the animals as whole seeds no pigmentation was observed [Bräutigam 2007].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

Front cover
Title page

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

RATANHIAE RADIX

2017

Rhatany Root

DEFINITION

Rhatany root consists of the dried, usually fragmented, underground organs of *Krameria triandra**) Ruiz et Pav., known as Peruvian rhatany. It contains minimum 5.0 per cent of tannins, expressed as pyrogallol ($C_6H_6O_3$; M_r 126.1) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Rhatany root].

* According to latest taxonomy *Krameria triandra* Ruiz & Pav. is considered to be a synonym of *Krameria lappacea* (Dombey) Burdet & B.B. Simpson [Medicinal Plant Names Services].

CONSTITUENTS

The main characteristic constituents are complex polyphenols (proanthocyanidins) consisting of 2-14 flavan-3-ol units with mainly 2,3-*cis* configuration, a predominant 4-8 interflavan linkage and a propelargonidin : procyanidin ratio of approximately 7:3 [Scholz 1989; Schilcher 2010; Blaschek 2016].

Lignans, neolignans and nor-neolignans, generally with an arylbenzofuran moiety, are also present [Stahl 1981; Arnone 1988, 1990; De Bellis 1994; Baumgartner 2011 a,b; Blaschek 2016], the most abundant ones being conocarpan and eupomatenoid 6 [Arnone 1988, 1990].

CLINICAL PARTICULARS

Therapeutic indication

Topical use
Minor inflammations of the mouth and throat such as stomatitis, gingivitis and pharyngitis [BHP 1996, Grünwald 2004; Schilcher 2010; Baumgartner 2011a; Blaschek 2016].

These indications are pharmacologically plausible and based on long-term use and experience.

Posology and method of administration

Dosage

Topical use
Crushed root, 1-2 g as a decoction or similar preparation as a rinse or gargle two to three times daily; tincture (1:5, ethanol 70% V/V), 5-10 drops in a glass of water two to three times daily; undiluted tincture painted on the affected surface two to three times daily [Grünwald 2004; Schilcher 2010; Blaschek 2016].

Method of administration
For local application.

Duration of administration
No restriction.

Contra-indications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

E/S/C/O/P
MONOGRAPHS

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
One case of contact dermatitis has been reported [Goday Buján 1998].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Radical scavenging effects
A methanolic extract (standardized to 15% neolignans) exhibited protective effects against haemolysis induced in red blood cells from rats by cumene hydroperoxide (IC_{50}: 0.28 µg/ml) or UVB radiation (IC_{50}: 0.78 µg/ml) and was much more effective than α-tocopherol (IC_{50}: 6.37 µg/ml). The extract (20 µg/ml) also showed protective effects on keratinocyte viability after UVB irradiation, increasing the survival rate to 96.5% ($p<0.001$) compared to 84.4% for the control [Carini 2002].

In a membrane model of lipid peroxidation (phosphatidylcholine liposomes), petroleum ether, chloroform and butyl acetate extracts inhibited lipid peroxidation during the propagation phase with IC_{50} values of 5.8, 3.7 and 0.23 µg/ml respectively [Maffei Facino 1997].

Anti-inflammatory activity
A dichloromethane extract (yield 5.5%) and various isolated lignan derivatives showed pronounced activity (>50% inhibition) at concentrations of 10 µg/mL in TNFα-stimulated HEK-293 cells stably transfected with a NF-kB-driven luciferase reporter gene. All compounds reduced NF-kB-dependent luciferase activity in a concentration-dependent manner. The extract (50 µg/mL) inhibited COX-1 by 82.5 ±8.9% and COX-2 by 83.9 ± 5.8%. Four of the lignans (50 µM) inhibited these enzymes to an extent of 57.2% to 83.3%. Moreover, the extract (50 µg/mL) and 3 of the lignans (50 µM) inhibited leukotriene formation by 69.5 ± 4.1% and between 80.2% and 94.6% respectively [Baumgartner 2011a].

Vasoprotective activity
In human umbilical vein endothelial cells (HUVECs) and HUVEC-derived EA.hy926 cells, the isolated compound 2-(2,4-dihydroxyphenyl)-5-(E)-propenylbenzofuran (DPPB) (1–10 µM) increased endothelial nitric oxide synthase (eNOS) activity. The effect was associated with an increase in Ca^{2+}, leading to the activation of eNOS via a signal transduction pathway involving Ca^{2+}/CaM, CaMKKb and AMPK [Ladurner 2012].

Antidiabetic activity
A dichloromethane extract (yield 5.5 %) at concentrations of 3-30 µg/mL concentration-dependently inhibited human recombinant PTP1B and enhanced insulin-stimulated glucose uptake in murine myocytes. The extract at a concentration of 30 µg/mL increased glucose uptake into murine C2C12 myocytes both in the absence and presence of insulin. Ratanhiaphenol III inhibited PTP1B with an IC_{50} of 20.2 µM and at concentrations of 10 and 30 µM concentration-dependently increased insulin receptor phosphorylation as well as insulin-stimulated glucose uptake in cultured myotubes [Heiss 2012].

Antiproliferative activity
An ethanolic extract (not further specified) showed a growth inhibition of Hep3B cells at concentrations of 50 and 100 µg/mL [Carras 2015].

Antimicrobial activity
Ethanol, methanol, hexane and ethyl acetate extracts inhibited the growth of various bacteria including *Escherichia coli* and *Staphylococcus aureus* [Neto 2002]. The MIC of a dry extract (obtained by percolation with acetone 80% and ethanol 80% followed by lyophilization of the combined extracts) against *S. aureus* was 20 µg/ml [Scholz 1989].

Certain neolignans and *nor*-neolignans isolated from rhatany root exhibited antibacterial and antifungal activity, inhibiting the growth of *E. coli*, *Aspergillus niger* and *Saccharomyces cerevisiae* [Arnone 1988; Bombardelli 1995].

No antimicrobial activity against *E. coli*, *S. aureus* or *A. niger* was observed with aqueous extracts [Anesini 1993].

Astringent activity
A tincture and a decoction of powdered rhatany root exhibited astringent activity, attributed mainly to proanthocyanidins with a degree of polymerization from 5-10; both preparations had a relative astringency of 0.3 (determined using freshly haemolyzed human blood) [Scholz 1989].

In vivo experiments

Anti-inflammatory activity
In a mouse ear model, a dichloromethane extract exhibited a dose-dependent inhibition of oedema which ranged from 24% at the lowest dose (30 µg/cm²) to 86% for the highest (300 µg/cm²) with an ID_{50} of 77 µg/cm². Eleven isolated compounds reduced the oedematous response from about 15% (0.1 µmol/cm²) to about 80% (1.0 µmol/cm²) in a dose-dependent manner (ID_{50} 0.31-0.60 µmol/cm²) comparable to the effect of indomethacin (ID_{50} 0.29 µmol/cm²) [Baumgartner 2011a].

Pharmacokinetic properties
No data available.

Preclinical safety data

Acute toxicity
No symptoms of toxicity were evident in rodents after a single dose of a dry extract (from combined acetone 80% and ethanol 80% percolates), administered orally at 300 mg/kg or intraperitoneally at 200 mg/kg [Scholz 1989].

Carcinogenicity
NIH black rats, 15 male and 15 female, 1-2 months old, were subcutaneously injected in the flank, weekly for a maximum of 75 weeks, with a total lyophilized extract (5 mg) or a tannin-containing fraction (2 mg) from rhatany root dissolved in 0.5 ml of saline solution; 30 control animals received saline only. The animals were observed for a period of 2 years. Both the extract and the tannin-containing fraction were shown to be carcinogenic in this experiment [Pradhan 1974]. However, in view of the high dose level and the duration and route of administration, the results do not appear to be relevant to the therapeutic use of rhatany root in humans [Simpson 1991].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

RHAMNI PURSHIANAE CORTEX

Cascara

DEFINITION

Cascara consists of the dried, whole or fragmented bark of *Rhamnus purshianus* D.C. (*Frangula purshiana* (D.C.) A. Gray ex J.C. Cooper). It contains not less than 8.0 per cent of hydroxyanthracene glycosides of which not less than 60 per cent consists of cascarosides, both expressed as cascaroside A ($C_{27}H_{32}O_{14}$; M_r 580.5) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Cascara].

CONSTITUENTS

The active constituents are hydroxyanthracene glycosides (8 – 10%) which can be subdivided into 3 groups [Staesche 2014; Sticher 2014; Manito 1995]:

- The mixed anthrone-C- and O-glycosides or the cascarosides (60 – 70%): cascarosides A - F and 10-hydroxycascaroside A,B,E and F. Cascarosides A and B are the 8-O-β-D-glucosides of 10-(S)-deoxyglucosyl aloe-emodin anthrone and of 10-(R)-deoxyglucosyl aloe-emodin anthrone (aloins A and B) respectively. Cascarosides C and D are the 8-O-β-D-glucosides of 10-(R)(S)-deoxyglucosyl chrysophanol anthrone (chrysaloins A and B); cascarosides E and F are 8-O-β-D-glucosides of 10-(R)(S)-deoxyglucosyl emodin anthrone.
- The pure anthrone-C-glycosides (10 – 30%): aloins A and B, 10-hydroxyaloins A and B together with chrysaloins A and B.
- The anthraquinone-O-glycosides (10-20%) including the monoglucosides of aloe-emodin, chrysophanol, emodin and physcion.

CLINICAL PARTICULARS

Therapeutic indications
For short term use in cases of occasional constipation [Staesche 2014; Veitch 2013; Wichtl 2009].

Posology and method of administration

Dosage
The correct individual dosage is the smallest required to produce a comfortable soft-formed motion.

Adults and children over 12 years
Preparations equivalent to 20-30 mg hydroxyanthracene derivatives, calculated as cascaroside A to be taken once daily at night [Martindale 2015; Staesche 2014; Veitch 2013; Wichtl 2009].

Elderly: dose as for adults.

Not recommended for use in children under 12 years of age.

The pharmaceutical form must allow for lower dosages.

Method of administration
For oral administration.

Duration of administration
Stimulant laxatives should not be used for periods of more than 2 weeks without medical advice. If symptoms persist after intake of the preparation medical advice should be sought [Tack 2011]

Contra-indications
Intestinal obstruction and stenosis, atony, inflammatory diseases of the colon (e.g. Crohn's disease, ulcerative colitis), appendicitis; abdominal pain of unknown origin; severe dehydration states with water and electrolyte depletion [Martindale 2015; Veitch 2013; Wichtl 2009; Pasricha 2006].

Special warnings and special precautions for use
As for all laxatives, cascara should not be given when any undiagnosed acute or persistent abdominal symptoms are present.

Chronic use may cause pigmentation of the colon (pseudomelanosis coli) which is harmless and reversible after drug discontinuation. Abuse with diarrhoea and consequent fluid and electrolyte losses may cause: dependence with possible need for increased dosages; disturbance of the water and electrolyte (mainly hypokalaemia) balance; an atonic colon with impaired function. Intake of anthranoid-containing laxatives for more than a short period of time may result in an aggravation of constipation. Hypokalaemia can result in cardiac and neuromuscular dysfunction, especially if cardiac glycosides, diuretics or corticosteroids are taken. Chronic use may result in albuminuria and haematuria.

If laxatives are needed every day the cause of the constipation should be investigated. Long term use of laxatives should be avoided. Use for more than 2 weeks requires medical supervision. In chronic constipation, stimulant laxatives are not an acceptable alternative to a change in dietary habits, physical activities and training for normal bowel evacuation [Martindale 2015; Veitch 2013; Keller 2011; Wichtl 2009; Pasricha 2006; Müller-Lissner 1993, 2005].

Interaction with other medicaments and other forms of interaction
Hypokalaemia (resulting from long term laxative abuse) potentiates the action of cardiac glycosides and interacts with antiarrhythmic drugs or with drugs which induce reversion to sinus rhythm (e.g. quinidine). Concomitant use with other drugs inducing hypokalaemia (e.g. thiazide diuretics, adrenocorticosteroids and liquorice root) may aggravate electrolyte imbalance [Staesche 2014; Veitch 2013; Wichtl 2009; Schulz 2004].

Pregnancy and lactation

Pregnancy
Not recommended during pregnancy.

Experimental studies as well as many years of experience do not indicate undesirable or damaging effects from anthranoid laxatives during pregnancy or on the foetus when used at the recommended dosage [Schmidt 1955; Westendorf 1993]. However, due to experimental data concerning a genotoxic risk from several anthranoids (e.g. aloe-emodin) a possible risk cannot be eliminated [Wichtl 2009].

Lactation
The use during breastfeeding is not recommended as there are insufficient data on the excretion of metabolites in breast milk. Small amounts of active metabolites (rhein) may appear in breast milk. However, a laxative effect in breast-fed babies has not been reported [Martindale 2015; Faber 1988].

Effects on ability to drive and use machines
None.

Undesirable effects
Abdominal spasms and pain, in particular with irritable colon; yellowish-brown or red (pH dependent) discolouration of urine by metabolites, which is not clinically significant [Martindale 2015; Tack 2011; Pasricha 2006; Schulz 2004; Tedesco 1985; Ewe 1986].

Overdose
The major symptoms are griping and severe diarrhoea with consequent losses of fluid and electrolytes, which should be replaced [Pasricha 2006]. Treatment should be supportive with generous amounts of fluid. Electrolytes, especially potassium, should be monitored; this is particularly important in the elderly and the young.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

Laxative activity
1,8-dihydroxyanthracene derivatives possess a laxative effect. The cascarosides and the anthrone-C-glycosides (aloins A and B, 10-hydroxyaloins A and B and chrysaloins A and B) are precursors which are not split by human digestive enzymes in the upper gut and therefore not absorbed. They are converted by the bacteria of the large intestine into the active metabolites mainly aloe-emodin-9-anthrone.

There are two different mechanisms of action:

(i) stimulation of the motility of the large intestine resulting in accelerated colonic transit and a decreased absorption of water and electrolytes (Na+, Cl-) into the colonic epithelial cells.

(ii) an influence on secretion processes by stimulation of secretion of water and electrolytes and increase of the leakage of the tight junctions resulting in enhanced fluid volume in the colon.

[Fairbairn 1965, 1970; Dreesen 1988; Hattori 1988; Che 1991; Akao 1996; Ishii 1990,1994a,1994b; 1998; Kai 2002; Alves 2004; Wanitschke 2003].

Possible mechanisms at cellular level are: inhibition of the sodium pump (Na^+/K^+-ATPase) [Ishii 1990; Rauwald 1992], Cl^--channels [Hönig 1992] and ATP-production [Rauwald 1992]; increase of NO [Izzo 1997; Park 2009a] and prostaglandins [Capasso 1983]; release of Ca^{2+}, histamine and serotonin [Park 2009a; Schulz 2004; Van Gorkom 1999].

Defaecation takes place after a delay of 6-12 hours due to the time taken for transport to the colon and transformation into the active compound [Staesche 2014; Martindale 2015; Müller-Lissner 2009; Pasricha 2006; Schulz 2004].

Antitumour activity
Aloe-emodin inhibited the growth of human neuroectodermal tumours in tissue cultures (ED_{50} 1-13 µg) and in mice with severe combined immunodeficiency (50 mg/kg b.w./day; $p<0.05$) [Pecere 2000].

Aloe-emodin inhibited cell proliferation in various hepatoma cell lines [Kuo 2002; Shieh 2003] and in Merkel carcinoma cell line [Wassermann 2002].

Furthermore, aloe-emodin demonstrated antiangiogenic activity by inhibiting NF-κB, basic fibroblast growth factors and iNOS [Srinivas 2007].

Other activities
Pretreatment of rats with aloe-emodin (2 x 50 mg/kg b.w. i.p.) significantly reduced acute liver injury induced by carbon tetrachloride ($p<0.05$). The changes in hepatic albumin and TNF-α mRNA were also normalized ($p<0.05$) [Arosio 2000].

Barbaloin and emodin showed a high affinity for phospholipids in different model membranes and exhibited antibacterial activity against *Escherichia coli* (MIC: 2.8 and 2.2 µM respectively) when incorporated into liposomes [Alves 2004].

Pharmacokinetic properties

No pharmacokinetic data have been directly obtained with cascara or its extracts. However, a human pharmacokinetic study using a mixture of aloins and their corresponding 3-rhamnosides (aloinosides A and B) has been reported. In this study, the equivalent of 16.4 mg of hydroxyanthracene derivatives was administered orally for 7 days during which aloe-emodin was detected only sporadically as a metabolite in the plasma, with maximum concentrations of less than 2 ng/mL. In the same study, rhein was detected in the plasma in concentrations ranging from 6-28 ng/mL (median C_{max} 13.5 ng/mL at median t_{max} 16 h) after single dose administration. In the 7-day administration there was no evidence of accumulation of rhein [Schulz 1993].

From another study it was concluded that free anthranoids absorbed systemically in humans are partly excreted in the urine as rhein or as conjugates even when rhein is not present in the administered drug (as in Cascara) [Vyth 1979]. It is not known to what extent aloe-emodin anthrone is absorbed. However, in the case of senna, animal experiments with radio-labelled rheinanthrone administered directly into the caecum show that only a very small proportion (less than 10%) of rhein anthrone is absorbed [De Witte 1988a].

Oral administration of emodin to rabbits at 10 mg/kg b.w. resulted in a very low serum concentration (approximately 2.5 µg/mL). Emodin was found to be highly bound (99.6%) to serum protein [Liang 1995].

An *in vitro* study using human intestinal cells (Caco-2) and the inverted rat gut sac showed an absorption of aloe-emodin of 6.6 to 11.3% at 5 to 50 µM [Park 2009b].

Systemic metabolism of free anthranoids depends upon their ring constituents [De Witte 1988b; Sendelbach 1989]. In the case of aloe-emodin, it was shown in animal experiments that at least 20-25 % of an oral dose will be absorbed. The bioavailability of aloe-emodin is much lower than the absorption, because it is quickly oxidized to rhein and an unknown metabolite, or conjugated. Maximum plasma values of aloe-emodin were reached 1.5-3 h after administration. Maximum concentrations in plasma were about 3 times higher than those in ovaries and 10 times higher than those in testes [Lang 1993].

Elimination of absorbed aglycones occurs via faeces and urine as glucuronides and sulfates [Sticher 2014].

Preclinical safety data

Acute toxicity
No mortality was observed in rats after a single oral administration of cascara at 6 g/kg and of aloin at 7.5 g/kg b.w. [Schmidt 1955]. Single oral doses of aloin at 50-500 mg/kg b.w. induced no toxic effects in rats [Bangel 1975]

Repeated dose toxicity
Cascara at a dose of 600 mg/kg b.w./day and aloin at a dose of 420 mg/kg b.w./day for 3 months showed low toxicity in rats [Schmidt 1955]. Aloin administered to rats at a dose of 200 mg/kg b.w./day, 2 days per week for 6 weeks also showed low toxicity [Bangel 1975]. Aloin at a dose of 100 mg/kg b.w./day for 20 weeks showed no specific toxic effects in mice [Siegers 1993].

Reproductive toxicity
Aloin at a dose of 200 mg/kg b.w. (for 1 day or 4 days during gestation) showed no evidence of any embryolethal, teratogenic or foetotoxic effects in rats [Bangel 1975].

Emodin, administered in feed to timed-mated rats (0, 425, 850 and 1700 ppm) and mice (0, 600, 2500 and 6000 ppm), was evaluated for potential effects on pregnancy outcome. Prenatal mortality, live litter size, foetal sex ratio and morphological development were unaffected in both rats and mice. At the highest dose, average foetal body weight per litter was unaffected in rats but was significantly ($p<0.001$) reduced in mice [Jahnke 2004].

Mutagenicity
No specific data are available for cascara or the cascarosides. Data for aloin derived from aloes indicate no genotoxic risk [Lang 1993; Bootman 1987a-b; CCR 1992a-c; Marquardt 1987]. Aloe-emodin showed positive and negative results *in vitro* but was clearly negative *in vivo* [Heidemann 1993]. Emodin was mutagenic in the Ames test [Brown 1976; Tikkanen 1983] but gave inconsistent results in gene mutation assays (V79 HGPRT) [Westendorf 1990; Bruggeman 1984], positive results in the UDS test with primary rat hepatocytes [Westendorf 1990] but negative results in the SCE assay [Bruggeman 1984].

Carcinogenicity
Data on the carcinogenicity of cascara or of the cascarosides are not available. Aloin fed to male NMRI mice in the diet at a level of 100 mg/kg/day for 20 weeks did not promote dimethylhydrazine-induced colorectal tumours [Siegers 1993].

In a 2-year study, male and female F344/N rats were exposed to 280, 830 or 2500 ppm emodin in the diet, corresponding to an average daily dose of emodin of 110, 320 or 1000 mg/kg b.w. in male rats and 120, 370 or 1100 mg/kg in female rats. No evidence of carcinogenic activity of emodin was observed in male rats. A marginal increase in the incidence of Zymbal's gland carcinoma occurred in the female rats treated with the high dosage but was interpreted as questionable [NTP 1999].

In a further 2-year study on $B6C3F_1$ mice, males were exposed to 160, 312 or 625 ppm emodin (equivalent to an average daily dose of 15, 35 or 70 mg/kg b.w.) and females to 312, 625 or 1250 ppm emodin (equivalent to an average daily dose of 30, 60 and 120 mg/kg b.w.). There was no evidence of carcinogenic activity in female mice. The low incidence of renal tubule neoplasms in exposed males was not considered relevant [NTP 1999].

Clinical safety data
In a case control study with retrospective and prospective evaluation, no causal relationship between anthranoid laxative use and colorectal cancer could be detected [Loew 1994a,1994b].

In one case report, cascara was reported to be associated with the development of cholestatic hepatitis, complicated by portal hypertension, after intake of 425 mg cascara (containing 5% cascarosides) 3 times daily for 3 days, but a causal relationship could not be demonstrated [Nadir 2000].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

RHEI RADIX

Rhubarb

2019

DEFINITION

Rhubarb consists of the whole or cut, dried underground parts of *Rheum palmatum* L. or of *Rheum officinale* Baillon or of hybrids of these two species or of a mixture. The underground parts are often divided; the stem and most of the bark with the rootlets are removed. It contains not less than 2.2% of hydroxyanthracene derivatives, expressed as rhein ($C_{15}H_8O_6$; M_r 284.2), calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Rhubarb].

CONSTITUENTS

The main characteristic constituents are hydroxyanthracene derivatives (3-12%, depending on the method of determination) consisting mainly (60-80%) of mono- and diglucosides of rhein, chrysophanol, aloe-emodin, physcion and emodin, and only small amounts of the respective aglycones. Dianthrone glycosides (sennosides) are also present and small amounts of anthrone glycosides depending on the time of harvesting and the conditions of drying [van Os 1976; Chirikdjian 1983; Engelshowe 1985; Hänsel 1994, 1999].

Other constituents include gallotannins (ca. 5%) [Engelshowe 1985; Weiß 1990; Hänsel 1994, 1999], chromones, phenylbutanones and traces of volatile oil [Hänsel 1994, 1999; Miyazawa 1996].

CLINICAL PARTICULARS

Therapeutic indications
For short-term use in cases of occasional constipation [Weiß 1990; Reynolds 1996; Wichtl 1997; Schilcher 2000].

Although no published clinical data is currently available, the laxative effect of rhubarb is well-known, and is comparable to the other anthranoid containing laxatives.

Posology and method of administration

Dosage

The correct individual dose is the smallest required to produce a comfortable soft-formed motion.

Adults and children over 12 years: drug or preparations equivalent to 15-50 mg of hydroxyanthracene derivatives (calculated as rhein) daily, preferably taken in one dose at night [Hänsel 1994; Wichtl 1997; Schilcher 2000].

Not recommended for use in children under 12 years of age.

The pharmaceutical form must allow lower dosages.

Method of administration
For oral administration.

Duration of use
Stimulant laxatives should not be used for periods of more than 2 weeks without medical advice.

Contraindications
Pregnancy and lactation; children under 10 years of age [Hänsel 1994].

Not to be used in cases of intestinal obstruction and stenosis, atony, inflammatory bowel diseases (e.g. Crohn's disease, ulcerative colitis), appendicitis, abdominal

E/S/C/O/P MONOGRAPHS

pain of unknown origin [Hänsel 1994]; severe dehydration states with electrolyte depletion.

Special warnings and precautions for use
As for all laxatives, rhubarb should not be given when any undiagnosed acute or persistent abdominal symptoms are present.

If laxatives are needed every day the cause of the constipation should be investigated. Long term use of laxatives should be avoided. Use for more than 2 weeks requires medical supervision. Chronic use may cause pigmentation of the colon (pseudomelanosis coli) which is harmless and reversible after drug discontinuation. Abuse, resulting in loss of fluid and electrolytes, may cause [Leng-Peschlow 1992]: dependence with possible need for increased dosages; disturbance of the water and electrolyte (mainly hypokalaemia) balance; an atonic colon with impaired function. Intake of anthranoid-containing laxatives for more than a short period of time may result in aggravation of constipation. Hypokalaemia can result in cardiac and neuromuscular dysfunction, especially if cardiac glycosides, diuretics or corticosteroids are taken. Chronic use may result in albuminuria and haematuria.

In chronic constipation, stimulant laxatives are not an acceptable alternative to a change in diet.

Note: A detailed text with advice concerning changes in dietary habits, physical activities and training for normal bowel evacuation should be included on the package leaflet. An example is given in the booklet "Médicaments à base de plantes" published by the French health authority (Paris: Agence du Médicament).

Interaction with other medicinal products and other forms of interaction
Hypokalaemia (resulting from long term laxative abuse) potentiates the action of cardiac glycosides and interacts with anti-arrhythmic drugs or with drugs which induce reversion to sinus rhythm (e.g. quinidine). Concomitant use with other drugs inducing hypokalaemia (e.g. thiazide diuretics, adrenocorticosteroids and liquorice root) may aggravate electrolyte imbalance.

Pregnancy and lactation

Pregnancy
Not recommended during pregnancy.
There are no reports of undesirable or damaging effects during pregnancy or on the foetus when used in accordance with the recommended dosage schedule. However, experimental data concerning a genotoxic risk from several anthranoids (e.g. emodin) are not counterbalanced by sufficient studies to eliminate a possible risk.

Lactation
Breast-feeding is not recommended as there are insufficient data on the excretion of metabolites in breast milk. Excretion of active principles in breast milk has not been investigated. However, small amounts of active metabolites (e.g. rhein) are known to be excreted in breast milk. A laxative effect in breast-fed babies has not been reported [Faber 1988].

Effects on ability to drive and use machines
None known.

Undesirable effects
Abdominal spasms and pain, in particular in patients with irritable colon; yellow or red-brown (pH dependent) discoloration of urine by metabolites, which is not clinically significant [Cooke 1977; Tedesco 1985; Ewe 1986].

Overdose
The major symptoms are griping and severe diarrhoea with consequent losses of fluid and electrolytes, which should be replaced.

Treatment should be supportive with generous amounts of fluid. Electrolytes, especially potassium, should be monitored; this is particularly important in the elderly and the young.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

1,8-dihydroxyanthracene derivatives possess a laxative effect [Fairbairn 1970; Leng-Peschlow 1992]. The β-linked glucosides in rhubarb are not absorbed in the upper gut; they are converted by the bacteria of the large intestine into active metabolites (anthrones).

Based on experimental studies and studies in humans with Tinnevelly senna pods and isolated sennosides, two distinct mechanisms of action are assumed [Leng-Peschlow 1986]:

i. an influence on the motility of the large intestine (stimulation of peristaltic contractions and inhibition of local contractions) resulting in accelerated colonic transit, thus reducing fluid absorption [Garcia-Villar 1980; Bueno 1980], and

ii. an influence on secretion processes (stimulation of mucus and active chloride secretion) resulting in enhanced fluid secretion [Leng-Peschlow 1986, 1989].

Defecation takes place after a delay of 8-12 hours due to the time taken for transport to the colon and metabolic conversion of hydroxyanthracene glycosides to the active compounds.

In vitro experiments

Antimicrobial activity
In an agar plate assay, strong inhibition of *Helicobacter pylori* was observed with a water extract (MIC < 1 mg) [Bae 1998]. An ethanolic extract inhibited *Helicobacter pylori* growth with a MIC of 17.24 µg/ml; in this test the MICs of anthraquinone compounds isolated from rhubarb were 0.40 µg/ml (emodin), 0.60 µg/ml (rhein), 0.78 µg/ml (chrysophanol) and 0.85 µg/ml (aloe-emodin) [Gou 1997].

Rhein, in combination with ampicillin or oxacillin, had synergistic or partial synergistic effects against methicillin-resistant *Staphylococcus aureus* strains (MRSA). The MIC of the respective antimicrobial agent in combination with rhein, compared to the antimicrobial agent alone, ranged 0.28-1 for ampicillin and 0.18-1 for oxacicillin [Joung 2012].

An ethanolic extract exhibited antiviral activity against *Herpes simplex* by preventing virus attachment and penetration [Hsiang 2001].

The antimycotic activity of an aqueous extract against *Aspergillus fumigatus* and *Candida albicans* was comparable to that of nystatin. The growth of *Geotrichum candidum* and *Rhodotorula rubra* was inhibited to a lesser extent [Blaszcyk 2000].

Rhein isolated from rhubarb showed strong antimicrobial activity against *Candida albicans* and *Bacteroides fragilis* [Cyong 1987].

Anti-proliferative activity
A dried aqueous extract (8:1) had significant ($p<0.001$) dose- and time-dependent growth inhibitory effects on both human lung adenocarcinoma cells and human breast cancer cells with IC_{50} values of 620 ±12.7 and 515 ±10.1 µg/ml respectively [Li 2009].

Rhein inhibited growth of three cancer cell lines in a dose dependent manner. The IC_{50} values against human cervical cancer cells, breast adenocarcinoma cells (MCF-7) and hepatocellular carcinoma cells (HepG2) were 54.28 ± 0.17, 49.35 ± 0.23 and 36.34 ± 0.14 µMol respectively ($p<0.05$) [Al-Fatlawi 2014].

Aloe-emodin induced apoptosis of human nasopharyngeal carcinoma cells via caspase-8-mediated activation of the mitochondrial death pathway [Lin 2010].

Emodin exhibited antiproliferative, antimetastatic and apoptotic effects in human chronic myelocytic leukemia K562 cells, pancreatic cancer cells, cervical cancer hela cells, hepatoma cells, neuroblastoma cells and tongue squamous cancer cells [Chun-Guang 2010, Liu 2011, Yaoxian 2013, Hsu 2010, Huang 2013, Lin 2009].

Several phenolic compounds from rhubarb showed cytotoxicity against human oral squamous cell carcinoma and salivary gland tumour cell lines as well as human gingival fibroblasts [Shi 2001]. Aloe-emodin induced apoptotic cell death in human lung squamous cell carcinoma [Lee 2001].

Bioassay-guided fractionation of an ethyl acetate extract showed emodin to be a selective inhibitor of casein kinase II with an IC_{50} of 2 µM [Yim 1999].

However, methanolic extracts from *Rheum palmatum* and *Rheum officinalis* rhizomes were found to significantly ($p<0.01$) enhance proliferation of the oestrogen-sensitive MCF-7 cell line at concentrations of 100 and 30 µg/ml, respectively. This effect was mainly attributed to emodin and emodin-8-*O*-β-D-glucoside, which bound to human oestrogen receptors α and β [Matsuda 2001].

Other effects
Methanolic extracts from *Rheum palmatum* and *Rheum officinale* showed radical scavenging activity, reducing 40 µM α,α-diphenyl-β-picrylhydrazyl (DPPH) radical by 50% at concentrations of 5.2 and 3.3 µg/ml respectively. IC_{50} values on superoxide anion radical in the xanthine/xanthine oxidase system were 5.0 and 3.8 µg/ml [Matsuda 2001]. Pyrogallol autoxidation and hydroxyl radicals generated via the Fenton reaction were inhibited by anthraquinones from rhubarb [Yuan 1997].

A hot water extract inhibited rat squalene epoxidase, an enzyme that catalyzes a rate-limiting step of cholesterol biosynthesis, by 70% at a concentration of 50 µg/ml; several galloyl compounds isolated from rhubarb were found to be potent inhibitors of the enzyme [Abe 2000].

A 90% hydroethanolic dried extract (3.4:1) was administered intragastrically to normal and CCl_4-treated rats daily for 12 weeks at dosage levels equivalent to 2, 5.4, 14.69 and 40g crude drug/kg b.w. A decrease in the extent of cellular injury was observed in the two lowest dosage groups of CCl_4-treated rats. However, a significant increase in fibrosis indicating rhubarb-induced liver damage was observed in both normal rats at all dosage levels and CCl_4-treated rats at the two highest dosage levels [Wang 2011].

In vivo experiments
In rats with adenine-induced chronic renal failure a hot water extract decreased levels of serum urea nitrogen and creatinine, as well as the hepatic urea concentration, in a dose-dependent manner. The effects were significant at doses of 15 and 35 mg/rat/day ($p<0.01$ to $p<0.05$) and 55 mg/rat/day ($p<0.001$). Hypocalcaemia, hyperphosphataemia and the concentrations of guanidino compounds in the serum, liver and kidney were improved. Proanthocyanidin oligomers were shown to be the active substances [Yokozawa 1984, 1986].

Rats with streptozotocin-induced diabetic nephropathy were treated orally with 125 mg/kg b.w./day of a hot water extract (drug to extract ratio 4:1) over a period of 80 days. At the end of the experimental period treated animals showed decreases in blood glucose levels, serum triglycerides and total cholesterol, and increases in urinary excretion of urea nitrogen and creatinine. All the changes were significant ($p<0.01$) compared to untreated controls [Yokozawa 1997].

A hot water extract was administered orally to rats after subtotal nephrectomy (SN) at a dose of 150 mg/day from day 30 to day 120. The treated animals had significantly less proteinuria ($p<0.05$) compared to untreated SN controls on days 90 and 120 after SN. Renal function was similar in the two groups, but the severity of glomerulosclerosis was significantly ($p<0.5$) reduced by the treatment [Zhang 1996].

Anti-inflammatory activity of rhubarb was demonstrated in 12-*O*-tetradecanoylphorbol-13-acetate (TPA)-induced mouse ear oedema. After single or multiple topical applications of TPA, an extract (50% ethanol, drug to extract ratio 3:1) applied topically at 0.5 mg/ear led to significant inhibition of oedema ($p<0.01$). Increased myeloperoxidase activity in the tissue after multiple applications of TPA was significantly reduced by the extract ($p<0.01$) [Cuéllar 2001].

Mice with streptozocin-induced diabetes were treated with emodin at 1.5 mg/kg i.p., daily for 3 weeks. The serum glucose level in the emodin-treated group was significantly ($p<0.01$) lowered compared to the diabetic control group. After 3 weeks glucose tolerance and insulin sensitivity in the emodin group were significantly ($p<0.05$) improved compared to control [Xue 2010].

In db/db mice treated daily for 2 weeks with either 100 mg/kg b.w. of rhein or emodin by oral gavage, total fat weight was significantly ($p<0.05$) decreased in the rhein group compared to an untreated control, whereas no effects were observed in the emodin group. In a further test, obesity was induced in C57BL/6 mice using a high fat diet. Mice were fed for 8 weeks with either a high fat diet mixed with 0.1% rhein or a high fat diet alone. At the end of treatment, body weight of the rhein-treated mice was significantly lower ($p<0.01$) than that of the high fat diet control group, indicating that rhein could block weight gain despite the amount of food intake in both groups being similar [Zhang 2012].

In mice on a high fat diet treated with rhein at 150 mg/kg b.w. by oral gavage, daily for 4 weeks, the expression of liver X target genes related to adipogenesis in white adipose tissue (regulating cholesterol homeostasis, lipid and energy metabolism) was significantly ($p<0.05$) suppressed compared to a high fat diet control [Sheng 2012].

Three groups of mice (n=10 each) were injected i.p. with myelomonocytic leukemia WEHI-3-cells and 2 weeks later began treatment for 14 days with a daily oral gavage of either 5 mg/kg or 10 mg/kg of emodin in olive oil or olive oil vehicle

only. Two further groups (n= 10 each) served as control (no treatment) or negative control (olive oil administration only). In comparison to the olive oil only treated leukemia mice group, CD19 and CD11b levels were significantly ($p<0.05$) increased in the 10 mg/kg and 5 mg/kg emodin groups respectively, whereas levels of CD3 were unaffected. The activity of peritoneal cavity phagocytes was significantly increased in the 5 mg/g emodin group ($p<0.05$) and in the 10 mg/kg emodin group ($p<0.001$) [Chang 2011].

Three weeks after transfection of nude mice with SW1990 pancreatic tumour cells, four groups (n=12 each) received ten i.p. injections (every three days) of either emodin (40 mg/kg), gemcitabine (125 mg/kg), emodin (40 mg/kg) plus gemcitabine (80 mg/kg) or isotonic saline. One week after the final injection (day 37), the tumour growth inhibition rate (difference of mean tumour volume between end and start of treatment in the treatment group divided by the respective difference in control group) was found to be high in the emodin and gemcitabine groups at 71.3 and 83.3% respectively, but highest in the combination group at 103.7% [Wei 2011].

Five groups of nude mice (n=5 each) were transfected with transplantable tumours induced by chronic myeloid leukemia K562 cells. After 12 days the groups were treated for 12 days with either 25, 50 or 100 mg/kg emodin, or 120 mg/kg hydroxy carbamide as positive control and isotonic saline as negative control. Tumour weight was reduced in the emodin groups, by 61.4% at 50 mg/kg ($p<0.05$) and by 75.6% at 100 mg/kg ($p<0.01$) and also in the positive control group by 78.3% ($p<0.01$) when compared to the negative control [Chun-Guang 2010].

Studies in humans

Although no published clinical data is currently available, the laxative effect of rhubarb is well-known, and is comparable to the other anthranoid containing laxatives.

Pharmacokinetic properties

No systematic data are available on rhubarb. It is assumed that aglycones present in the drug are absorbed in the upper gut, and that (by analogy with sennosides from senna) the β-linked glucosides are neither absorbed in the upper gut nor split by human digestive enzymes. They are converted by the bacteria of the large intestine into aglycones and subsequently to the active compounds, the anthrones [Kobashi 1980].

In rat liver microsomes emodin was metabolized to 6-hydroxy-aloe-emodin and 2-hydroxyemodin, and chrysophanol was converted to aloe-emodin [Mueller 1998].

Preclinical safety data

There are no studies on single dose toxicity, repeated dose toxicity, reproductive toxicity or *in vivo* tests on carcinogenicity of rhubarb or preparations from it. In the *Salmonella* microsome assay an ethanolic extract showed mutagenic effects against *S. typhimurium* strain TA 1537 [Paneitz 1999]. Some isolated anthraquinones (aloe-emodin, emodin, physcion and chrysophanol) gave positive results in *in vitro* genotoxicity studies [Bruggemann 1984; Westendorf 1990; Heidemann 1993, 1996]. All *in vivo* genotoxicity studies were negative [Heidemann 1993, 1996; Mengs 1997]. Sennosides A and B and rhein gave negative results in *in vitro* and *in vivo* mutagenicity tests [Heidemann 1993; Mengs 1993].

In a 2-year study, male and female F344/N rats were exposed to 280, 830 or 2500 ppm of emodin in the diet, corresponding to an average daily dose of emodin of 110, 320 or 1000 mg/kg b.w. in male rats and 120, 370 or 1100 mg/kg b.w. in female rats. No evidence of carcinogenic activity of emodin was observed in male rats. A marginal increase in the incidence of Zymbal's gland carcinoma occurred in female rats treated with the high dosage but was interpreted as questionable [NIH Publication 1999].

In a further 2-year study, on B6C3F1 mice, males were exposed to 160, 312 or 625 ppm of emodin (corresponding to an average daily dose of 15, 35 or 70 mg/kg b.w.) and females to 312, 625 or 1250 ppm of emodin (corresponding to an average daily dose of 30, 60 or 120 mg/kg b.w.). There was no evidence of carcinogenic activity in female mice. A low incidence of renal tubule neoplasms in exposed males was not considered relevant [NIH Publication 1999].

A 90% hydroethanolic dried extract (3.4:1) was administered intragastrically to normal and CCl_4-treated rats daily for 12 weeks at dosage levels equivalent to 2, 5.4, 14.69 and 40g crude drug/kg b.w. Although a decrease in the extent of cellular injury was observed in the two lowest dosage groups of CCl_4-treated rats, a significant increase in fibrosis indicating rhubarb-induced liver damage was observed in both normal rats at all dosage levels and CCl_4-treated rats at the two highest dosage levels [Wang 2011].

Clinical safety data

Despite a lack of formal preclinical data on rhubarb, epidemiological studies suggest that there is no carcinogenic risk to humans from the use of anthranoid laxatives [Siegers 1993; Nusko 1993; Sonnenberg 1993; Kune 1993, 1996; Loew 1996, 1997].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

RIBIS NIGRI FOLIUM 2017

Black Currant Leaf

DEFINITION

Blackcurrant leaf consists of the dried leaf of *Ribes nigrum* L. It contains not less than 1.0 per cent of flavonoids, expressed as isoquercitroside ($C_{21}H_{20}O_{12}$; M_r 464.4) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Blackcurrant leaf].

CONSTITUENTS

Characteristic constituents are: mono- and diglycosides of quercetin, kaempférol and isorhamnetin, mainly isoquercitroside and its malonic acid ester [Vagiri 2012, Vagiri 2015]; a flavanone, sakuranetin [Altkinson 1982]; monomeric flavanols (mainly gallocatechin and epigallocatechin) [Buzun 1978; Tits 1992a; Tits 1992b]; proanthocyanidins [Buzun 1978; Tits 1991; Tits 1992a; Tits 1992b], especially di- and trimeric prodelphinidins [Tits 1991; Tits 1992a; Tits 1992b]; hydroxycinnamic acid derivatives including chlorogenic, caffeic and *p*-coumaric acids [Trajkovski 1974]; phenolic acids as gallic and gentisic acids [Tabart 2011]; and traces of essential oil [Andersson 1963; Seitz 2014].

CLINICAL PARTICULARS

Therapeutic indications

Adjuvant in the treatment of rheumatic conditions [Decaux 1930; Garnier 1961; Cassis 1978; Seitz 2014; Leclerc 1983; Wichtl 2009].

In this indication, the efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adults: Dried leaf as an infusion (20-50 g/litre, infused for 15 minutes), 250-500 ml daily [Cassis 1978; Leclerc 1983; Wichtl 2009]; fluid extract (1:1), 5 ml twice daily, taken before meals [Decaux 1930; Cassis 1978; Leclerc 1983; Wichtl 2009].

Method of administration
For oral administration.

Duration of use
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contra-indications
None known.

Special warnings and precautions for use
None required.

Interaction with other medicinal products and other forms of interaction
None reported.

Pregnancy and lactation
In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Anti-inflammatory effects
A purified flavonoid extract obtained from blackcurrant leaf inhibited the biosynthesis and release of prostaglandins (IC_{30}: 1.03 mg/ml flavonoids) in isolated perfused rabbit heart. The flavonoid extract was 2.2 and 3.6 times more effective than isoquercitroside and rutin respectively [Pham Huu Chanh 1986].

Di- and trimeric prodelphinidins isolated from blackcurrant leaf were investigated for their effects on the metabolism of human chondrocytes and potential inhibition of COX-1 and COX-2. At the end of a 12-day incubation with 10 µg/ml of prodelphinidin, proteoglycans and type II collagen production were significantly increased in human chondrocytes ($p<0.025$ and $p<0.01$). Under the same conditions, inhibition of PGE_2 synthesis was observed in the presence of di- and trimeric prodelphinidins at a dose of 10 µg/ml ($p<0.025$ and $p<0.01$ respectively). An *in vitro* test on purified COX-1 and COX-2 showed a preferential inhibition of COX-2 (53.2±4.0%) compared to COX-1 (8.1±13.9%) at a concentration of 10^{-5} M dimeric procyanidin. However, no effect was observed on COX activity in the whole blood assay [Garbacki 2002].

In human endothelial LT2 cells, pre-treated for 24 h with a proanthocyanidin-enriched fraction from blackcurrant leaf (mixture of catechin, gallocatechin, di- and trimeric prodelphinidins) [Tits 1992 a] and activated with TNF-α, the cell adhesion immunoglobulin was dose dependently and significantly (10, 30 and 60 µg/ml) inhibited ($p<0.05$ or $p<0.01$). The same fraction did not significantly modify expression of IL-8 and vascular endothelial growth factor 165 (mediators involved in inflammatory processes associated with angiogenesis) [Garbacki 2005].

Antioxidant effects
Antioxidant properties of methanolic crude extracts from fresh blackcurrant leaf (2.4 g in 50 ml) of three different varieties were demonstrated by measuring the inhibition of lipid oxidation induced in rat liver microsomes by ferrous sulfate-ADP-ascorbic acid (IC_{50}: 6.44-7.29µl of methanolic extract per ml) or by *t*-butyl hydroperoxide (IC_{50}: 8.63-9.31 µl of methanolic extract per ml) [Costantino 1993].

A dry extract containing 11.9% flavonol glycosides (not further defined) suppressed the oxidation of erythrocyte membrane lipids induced by UV-C (IC_{50}: 22.8-24.2 µg/ml) and 2,2'-azobis (2-amidinopropane) dihydrochloride (IC_{50}: 7.15-7.25 µg/ml). The control substance, Trolox, showed IC_{50} values of 13.3-15.9 µg/ml and 3.6-4.2 µg/ml respectively [Bonarska-Kujawa 2014].

In vivo experiments

Anti-inflammatory effects
A 14%-ethanolic extract from blackcurrant leaf (60 g per litre), administered orally at 1 and 10 ml/kg b.w., produced dose-dependent anti-inflammatory effects corresponding respectively to 30% and 54% reductions in carrageenan-induced rat paw oedema compared to controls. Comparable activities were observed with reference substances: indometacin produced 63% reduction at 2.5 mg/kg and 66% at 5 mg/kg; niflumic acid produced 19% reduction at 25 mg/kg and 70% at 50 mg/kg. A 21-day oral treatment with the extract reduced oedema compared to control animals by 30% at 0.33 ml/kg, 42.5% at 1 ml/kg and 46% at 10 ml/kg, the last being statistically identical with the activities of indometacin at 1.66 mg/kg (49% reduction) and niflumic acid at 12.5 mg/kg (53% reduction). A 21-day oral treatment with a lyophilizate of the 14%-ethanolic extract (1 g of lyophilizate equivalent to 30 ml of extract or 1.8 g of leaf) gave an ED_{50} of 0.67 g/kg for the lyophilizate compared to 0.43 mg/kg for indometacin. The efficacy of the blackcurrant leaf extract was apparent in both the proliferative and exudative phases of inflammation [Declume 1989].

A lyophilizate prepared after maceration of blackcurrant leaf (100 g/litre) in 15% ethanol for 10 days at 20°C and administered intraperitoneally to rats exhibited potent anti-inflammatory activity in comparison with controls [Mongold 1993]. In the carrageenan-induced rat paw oedema test at 50 and 100 mg/kg b.w., the lyophilizate produced dose-dependent inhibition of inflammation ($p<0.01$), its effect at 100 mg/kg (70% inhibition) being similar to that of indometacin at 5 mg/kg (77% inhibition). In the cotton pellet-induced granuloma test, the lyophilizate at 150 mg/kg reduced inflammation by 18.6%, comparable to the 24% reduction with indometacin at 3 mg/kg. In the Freund adjuvant-induced arthritis test, the lyophilizate produced a dose-dependent reduction in inflammation of 18.7% at 150 mg/kg and 34.6% at 300 mg/kg, the latter being statistically identical to the 37.7% reduction obtained with indometacin at 3 mg/kg [Mongold 1993].

Prodelphinidins isolated from blackcurrant leaf, administered intraperitoneally, had a dose-dependent anti-inflammatory effect in the carrageenan-induced rat paw oedema model: 18%, 40% and 55% reductions in inflammation with 5, 10 and 40 mg/kg respectively. In a similar experiment, a crude aqueous extract from blackcurrant leaf produced 57% inhibition at 60 mg/kg, comparable to 44% with indometacin at 4 mg/kg and 47% with aspirin at 200 mg/kg [Tits 1992b].

Treatment of rats with a proanthocyanidin-enriched fraction from blackcurrant leaf [Tits 1992 a] (10, 30, 60 and 100 mg/kg, i.p.) significantly ($p<0.05$) reduced paw oedema induced by carrageenan in a dose and time-dependent (from 0 to 4 h) manner and also dose-dependently significantly inhibited ($p<0.05$) carrageenan-induced pleurisy in rats. The same fraction at 30 mg/kg also significantly lowered ($p<0.05$) TNF-α, IL-1β and nitrite/nitrate levels in pleural exudate [Garbacki 2004].

In rats treated with the same fraction (10, 30 and 60 mg/kg, i.p.) before intrapleural injection of carrageenan, exudate volume was significantly reduced ($p<0.05$ or $p<0.01$) in a dose-dependent manner (31, 37 and 55% respectively) 4 hours after injection. Infiltration of polymorphonuclear leucocytes was also significantly inhibited ($p<0.01$) in a dose-dependent manner (64, 73 and 75% respectively) [Garbacki 2005].

Analgesic effects
A lyophilizate prepared after maceration of blackcurrant leaf (100 g/litre) in 15% ethanol for 10 days exhibited potent analgesic activity, which may be of peripheral origin, in the acetic acid-induced writhing test after single dose i.p. administration to mice. The lyophilizate had an ED_{50} of 61.5 mg/kg and a therapeutic index (LD_{50}/ED_{50}) of 17.7. Paracetamol (acetaminophen) administered to the control group gave a higher ED_{50} of 132 mg/kg and a lower therapeutic index of 3.8 [Mongold 1993].

Diuretic activity
A fluid extract (1:1) of blackcurrant leaf showed a salidiuretic action (diuretic quotient 1.56) in rats when administered orally at a dose equivalent to 1500 mg dried leaf/kg; this was similar

to the effect of furosemide at 50 mg/kg (diuretic quotient 1.52) [Rácz-Kotilla 1977].

The potassium-sodium ratios in blackcurrant leaf and blackcurrant leaf decoction were found to be 128:1 and 242:1 respectively, which may contribute to a diuretic effect [Szentmihályi 1998].

Antihypertensive effects
A fluid extract (1:1) of blackcurrant leaf had an antihypertensive effect on cats, with an antihypertensive quotient of 1.82 at an oral dose equivalent to 400 mg dried leaf/kg, the effect lasting for 15-20 minutes; tolazoline had comparable antihypertensive quotients, 1.69 at 0.75 mg/kg and 2.12 at 1.0 mg/kg, but the effect lasted for only 5 minutes [Rácz-Kotilla 1977].

An infusion of blackcurrant leaf (20 g/litre), administered intravenously to normotensive rats at a dose equivalent to 360 mg dried leaf/kg b.w., produced a rapid fall of 45% in arterial blood pressure and the decrease was still 30% after 30 minutes [Lasserre 1983].

Pharmacokinetic properties
No data available.

Preclinical safety data
A lyophilized 14%-ethanolic extract (1 g of lyophilizate equivalent to 1.8 g of blackcurrant leaf), administered orally to rats at 2 g/kg/day for 21 days or 1.34 g/kg/day for 28 days, revealed no signs of toxicity and no gastric ulceration was observed [Declume 1989].

Rats treated orally for 28 days with a lyophilizate prepared after maceration of blackcurrant leaf (100 g/litre) in 15% ethanol for 10 days had no gastric ulceration. Compared to control animals no changes were apparent in food and fluid consumption or b.w., nor in results from blood analysis and histopathological evaluation of 14 different organs. In an acute toxicity study of the same lyophilizate in mice, the i.p. LD_{50} was 1.09 g/kg; oral doses up to 3 g/kg showed no overt toxicity [Mongold 1993].

The i.p. LD_0 and LD_{50} values of a blackcurrant leaf fluid extract (1:1) in mice were 22 and 49 g/kg respectively [Rácz-Kotilla 1977].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

RUSCI RHIZOMA

2017

Butcher's Broom

DEFINITION

Butcher's Broom consists of the dried, whole or fragmented underground parts of *Ruscus aculeatus* L. It contains not less than 1.0 per cent of total sapogenins, expressed as ruscogenins [a mixture of neoruscogenin ($C_{27}H_{40}O_4$; M_r 428.6) and ruscogenin ($C_{27}M_{42}O_4$; M_r 430.6)] and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Butcher`s Broom].

CONSTITUENTS

The characteristic constituents are steroidal saponins based upon (25*R*)-spirost-5-ene-1β,3β-diol (ruscogenin) and spirosta-5,25(27)-diene-10,3β-diol (neoruscogenin), such as ruscoside, ruscin, deglucoruscoside and deglucoruscin. Minor constituents include flavonoids, anthraquinones, benzofurans, the coumarin esculin, essential oil (mainly monoterpenes) and sterols [Rauwald 1988; Schneider 1990; Mimaki 1998a, 1998b; Mari 2012; Barbic 2013; Sticher 2015].

CLINICAL PARTICULARS

Therapeutic indications
Supportive therapy for symptoms of chronic venous insufficiency, such as painful, tired and heavy legs, tingling and swelling [Vanscheidt 2002; Boyle 2003; Aguilar Peralta 2007; Lascasas Proto 2009; Guex 2010]. Supportive therapy for symptoms of haemorrhoids, such as itching and burning [Anger 1981; Willuhn 2009; Abascal 2005].

Posology and method of administration

Dosage
Adult daily dose: Solid or liquid extracts in amounts corresponding to 7-11 mg of total ruscogenins [Willuhn 2009].

Method of administration
For oral administration.

Duration of administration
No restriction; long-term administration may be advisable. If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

No adverse effects have been reported in mothers or newborn babies when used in late pregnancy [Anger 1981; Baudet 1991].

Effects on ability to drive and use machines
None known.

Undesirable effects
Contact allergy to ruscogenins might occur in rare cases [Elbadir 1998].

E/S/C/O/P
MONOGRAPHS

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In some studies, combinations have been used, consisting of an extract (not further specified) plus hesperidin methyl chalcone as well as in some cases ascorbic acid. In the text, these preparations are indicated by the term "a combination".

In vitro experiments

Vasoconstriction
In rings of saphenous vein from ovariectomized female rabbits, an extract (prepared using DMSO with further dilution in distilled water) (0.001-1 mg/mL) induced dose-dependent contractions. This effect was insensitive to blockade by either prazosin (3×10^{-7} M) or rauwolscine (10^{-7} M), but was partially inhibited by both substances in rings isolated from oestradiol-treated animals [Harker 1988].

A hydroalcoholic extract (not further specified) caused dose-dependent contraction in segments of isolated canine saphenous veins (effective dose: 30 µg/mL and higher). The maximal contraction caused by the extract averaged 80 ± 12% of the response to 10^{-4} M noradrenaline. Prazosin and rauwolscine given alone decreased, and the presence of both substances eliminated, the response to the extract (0.1-1 mg/mL, n = 5 each concentration). Cocaine reduced the contraction evoked by butcher's broom extract suggesting also an indirect sympathomimetic effect of the extract. The contractile response to the extract was also depressed by phentolamine, adenosine, verapamil and by sympathectomy with 6 hydroxydopamine. Tetrodotoxin, atropine, methysergide and indometacin did not significantly influence the effect of butcher's broom extract; acetylcholine enhanced the increase in tension [Marcelon 1983,1984,1988].

Femoral vein rings and coronary arterial rings were isolated from adult female mongrel dogs. An extract (not further specified; 0.001-1 mg/mL) induced dose-dependent contractions of the vein preparations. The effect was modulated by the integrity of the endothelial cells and the hormonal status of the animals. Treatment with prazosin plus rauwolscine reduced the contractions evoked by the extract following progesterone treatment; inhibition of α-adrenergic receptors in veins from oestrogen-treated animals augmented the contractions evoked by the combination [Miller 1991a,b]. In both the venous and arterial rings with endothelium, the extract (4-6 g/mL) relaxed contractions induced by noradrenaline (veins) or prostaglandin F2a (PGF2a; arteries) in a dose-dependent manner. The relaxing effect was inhibited by atropine and by inactivation of the endothelial relaxing factors [Miller 1991a].

An extract (not further specified; 0.001-1 mg/mL) induced dose-dependent contractions in rings from greater saphenous veins and varicose tributaries of patients (3 male, 17 female), who underwent vein stripping for primary varicosity (n = 5-7 for each experiment). Blocking of α- and β-adrenergic receptors with phentolamine and propranolol reduced the maximal tonus induced by butcher's broom extract in each type of vein [Miller 1994].

An extract (not further specified) caused comparable and moderate contraction of human saphenous veins with and without endothelium isolated from healthy volunteers (n = 8; 3 females, 5 males) and patients with primary varicosity (n = 14; 11 female, 3 male). The threshold dose ranged between 0.01 and 0.1 mg/mL. Contractions of the varicose tributaries were about two-fold greater than those of saphenous veins from the same patients. In veins from varicose patients, α_2-blockade with rauwolscine was more effective than α_1-blockade with prazosin in reducing contractions induced by butcher's broom in rings with and without endothelium [Miller 2000].

Maximal contractions induced by an extract (not further specified; 1 mg/mL) in veins taken from women undergoing varicectomy were independent from the oestrogen level during the menstrual cycle. Comparable effects were seen in veins from menopausal women [Marcelon 1988a].

A water-soluble extract (not further specified; 0.01, 0.1 and 1 mg/mL) caused dose-dependent reduction of noradrenaline accumulation in isolated normal and varicose human saphenous veins. The highest concentration caused a reduction of about 50% in the normal vein and reduced the formation of all metabolites of noradrenaline [Branco 1988].

Saponin mixtures and ruscogenin provoked remarkable vasoconstrictive effects in the isolated rabbit ear. The ED_{50} of ruscogenin was 20-25 fold lower than for the saponins [Capra 1972].

Effects on permeability
Damage to isolated pig ear vein induced by ethacrynic acid was diminished by pre-incubation with an extract (not further specified; 0.05%). This effect was related to reduced permeability to both water and protein [Hönig 1989].

Vasoprotection
In the presence of an extract (not further specified), the viability of human umbilical vein endothelial cells exposed to hypoxia increased by up to 60%. A pronounced effect was observed when cells under hypoxia were incubated for 48 hours with concentrations above 330 µg/mL [Baurain 1994]. The extract at 0.05 µg/mL provided only slight protection from the hypoxia-induced decrease in ATP, while 50 µg/mL totally prevented the effect of hypoxia (n=9 for each concentration). Inhibition of phospholipase A2 activation by 50%, observed with the extract at 0.05 µg/mL, increased only slightly with higher concentrations (0.5 µg/mL, 5 µg/mL and 50 µg/mL). The extract also dose-dependently inhibited hypoxia-induced adherence of neutrophils to the endothelial cells: 0% at 0.05 µg/mL and 88% at 50 µg/mL [Bouaziz 1999].

Effects on lymphatic vessels
Noradrenaline (10^{-8} to 10^{-4} M) and a combination (0.01-1 mg/mL) caused dose-dependent contractions in isolated canine lymphatic thoracic duct. The activity of the combination was partially inhibited by prazosin and rauwolscine, whereas phentolamine completely eliminated the contractile response [Marcelon 1988b].

Addition of an extract (not further specified; 30 µg/mL) increased the contraction frequency caused by electrical field stimulation in isolated bovine mesenteric lymphatic vessels (n = 8) by about 50%. Noradrenaline blocked the response to the field stimulation (n = 6) [McHale 1991].

Antioxidant effect
Ruscogenin showed antioxidative effects against Formyl-Met-Leu-Phe (FMLP)-induced extra- and intracellular superoxide generation in mouse bone marrow neutrophils, with IC_{50} values of 1.07 ± 0.32 µM and 1.77 ± 0.46 µM respectively. Phorbol myristate acetate (PMA)-elicited extra- and intracellular superoxide generation were also suppressed by ruscogenin, with IC_{50} values of 1.56 ± 0.46 µM and 1.29 ± 0.49 µM

respectively. Furthermore, it inhibited the membrane translocation of p47phox and p67phox and reduced FMLP-induced phosphorylation of cytosolic phospholipase A2 (cPLA2) and p21-activated kinase (PAK). The cAMP levels and PKA expression were increased by ruscogenin. Ruscogenin inhibited phosphorylation of protein kinase B (Akt), p38 mitogen-activated protein kinase (p38MAPK), extracellular signal-regulated kinase 1 and 2 (ERK1/2), and c-Jun N-terminal kinase (JNK). The inhibitory effects of ruscogenin on superoxide production and the phosphorylation of Akt, p38MAPK, and ERK1/2 were reversed by PKA inhibitor (H89) [Lin 2015].

Anti-inflammatory effect
Ruscogenin significantly suppressed zymosan A-evoked peritoneal total leukocyte migration in mice in a dose-dependent manner (1 and 3 mg/kg), while these concentrations had no effect on PGE2 content in peritoneal exudate. At a concentration of 1μM, ruscogenin also inhibited TNFα-induced over-expression of ICAM-1 both at mRNA and protein levels and considerably suppressed NF-κB activation by decreasing NF-κB p65 translocation and DNA binding activity [Huang 2008].

Elastase activity
Ruscogenins inhibited the activity of porcine pancreatic elastase (IC_{50}: 119 μM; competitive inhibition) [Maffei Facino 1995].

Antimicrobial effect
A dry extract (70% methanol) was active against 8 bacteria and 5 fungi (MIC between 0.2 and 1.00 mg/mL). The antifungal activity against *Trichoderma viride* exceeded the one of the positive controls, ketoconazole [Hadžifejzović 2013].

In vivo experiments

Vasoconstriction
An extract (not further specified) was added to the superfusion solution applied to cheek pouch preparations of male hamsters. The venules constricted with doses above 0.05 mg/mL/min, while arterioles remained unchanged. Venular constriction evoked by the extract at 0.2 mg/mL/min was blocked by prazosin (10^{-9} M), by diltiazem (10^{-9} M) and by high concentrations of rauwolscine (10^{-6} M) [Bouskela 1994a].

The vasoconstrictive effects of an extract (not further specified) applied topically to hamster cheek pouch preparations were found to be temperature-dependent. At 25°C venules and arterioles dilated. At 36.5°C venules constricted, whereas arterioles either dilated with extract concentrations of up to 0.05 mg/mL or remained unchanged even with higher concentrations of the extract. At 40°C constriction of venules was more pronounced than at the lower temperatures, whereas arterioles only constricted with higher concentrations of the extract (above 0.01 mg/mL) [Bouskela 1991].

Intravenous administration of an extract (not further specified) at 5 mg/kg b.w. caused venular constriction in the cheek pouch of male hamsters, but did not affect the arteriolar diameter. Mean arterial pressure was not affected at this dose level [Bouskela 1991].

Oral administration of a solution of an extract (not further specified) at 150 mg/kg b.w. for 28 days resulted in constriction of the venules by 30% and dilatation of the arterioles by 37% in the hamster cheek pouch (n = 6) compared to water-treated controls (n = 6). Arteriolar and venular side branches were not affected [Bouskela 1991].

The vasoconstrictive effects of an extract (not further specified) were investigated in lower leg muscle preparations of 12 anaesthetized young adult cats. Following intra-arterial administration of 0.4 mg/min/kg b.w., arterial, arteriolar and venular resistance increased by 30-35% within 90 seconds, while higher doses (0.8 mg/min/kg and 3 mg/min/kg) produced sustained dilator effects. This pattern of response was consistent in all experiments (n = 24). Intravenous administration of the extract at 1-9 mg/min/kg resulted in a dose-dependent venoconstrictive response (n = 10) [Mellander 1991].

In dogs (n = 4), constant infusion of an extract (not further specified) at 50 μg/hour/kg b.w. for 5 days (total doses: 60-84 mg) had beneficial effects on alterations caused by denervation of the lateral saphenous vein segments, with the increase in smooth muscle cell diameter being completely prevented. The extract increased the O-methylating capacity of the denervated and the non-denervated tissues [Teixeira 1988].

Effect on permeability
Topical application of an extract (not further specified; 0.002-2.0 mg/mL/min) to male hamster cheek pouch preparations dose-dependently inhibited the increase in macromolecular permeability caused by histamine. A concentration of 0.2 mg/mL/min elicited 50% inhibition of the histamine-induced permeability. This effect was blocked by prazosin and by diltiazem, but not by rauwolscine (all applied topically) [Bouskela1994b].

An intravenously administered extract (not further specified) at 5 mg/kg b.w. showed protective effects against leakage of dextran in the hamster cheek pouch after topical administration of various permeability-increasing substances such as bradykinin, leukotriene B_4 or histamine [Bouskela 1993].

Two isolated saponins and esculin were tested for their activity against hyperpermeability in endothelial cells induced by thrombin. The saponins reduced permeability to 41.9% and 42.6% whereas esculin reduced it to 53.3% [Barbic 2013].

Oedema-protective effect
The oedema-protective effects of an extract (containing 2.5% of ruscogenin) and ruscogenin were demonstrated in a perfusion model of the hindleg of anaesthetized cats. Oedema was induced by perfusion with 0.1% of ethacrynic acid for 10 minutes. The extract (200 or 400 mg/kg b.w.) or ruscogenin (20 or 80 mg/kg b.w.) were administered orally 4 hours before induction of oedema. Alternatively, the extract at 10 or 20 mg/kg or ruscogenin at 4 mg/kg were administered intravenously 1 hour prior to oedema induction. Each treatment group comprised 5 or 6 animals and 16 animals served as controls. After an additional 45-minute perfusion with 0.9 % sodium chloride solution, the blood, protein and water contents in the oedema of the skin and muscle were measured. The optimal protective dose of the extract was 20 mg/kg b.w. when administered intravenously, whereas an oral dose 10- to 20-fold higher was necessary. An intravenous dose of ruscogenin at 4 mg/kg b.w. was as effective as an oral dose of 20 mg/kg [Felix 1983].

Anti-inflammatory effect
An extract (not further specified) showed anti-inflammatory activity in rats when administered by the intraperitoneal (100, 200 or 300 mg/kg b.w.) or the rectal route (suppositories, 275 mg/kg b.w.). The effect of 300 mg/kg of the extract (i.p.) was equivalent to 72% of the activity of phenylbutazone (165 mg/kg i.p). Two other purified extracts with higher concentrations of ruscogenins were effective at lower doses [Chevillard 1965].

In rats oedema was induced by injection of dextran, histamine, serotonin or hyaluronidase. Intraperitoneal administration of purified sapogenins from butcher's broom at 20, 40 or 80 mg/

kg b.w. reduced limb oedema; this antiphlogistic activity was suppressed by adrenalectomy. Slight anti-inflammatory activity was observed against granulomas induced by subcutaneous implantation of cotton pellets. When the purified sapogenins were administered orally neither antiphlogistic nor anti-inflammatory activity was observed [Cahn 1965].

Saponins and ruscogenins isolated from butcher's broom showed anti-inflammatory activity in carrageenan- and brewer's yeast-induced rat paw oedema when administered intraperitoneally or intravenously. In the rabbit, only the ruscogenins (80 mg/kg b.w. i.p.) decreased capillary permeability significantly ($p = 0.05$). These substances were not active against capillary fragility [Capra 1972].

Effect on lymph vessels
Intravenous administration of a water-soluble extract (not further specified) at 1, 2 or 5 mg/kg b.w. dose-dependently enhanced flow duration and intensity in isolated lymph vessels of anaesthetized dogs. A similar effect was seen in the veins. The activity of the extract was not influenced by injection of nifedipine [Pouget 1991].

Pharmacological studies in humans
In a randomized, double-blind, crossover, 4-armed study, 20 healthy volunteers (11 men and 9 women aged between 20 and 43 years) took a single oral dose of four different treatments, separated by 1-week wash-out periods: 450 mg of an extract, 450 mg of trimethylhesperidin chalcone (TMHC), a combination of both substances, or a placebo. Venous function, capillary filtration rate, tissue and blood volume were monitored before intake and after 50, 70, 90, 120 and 150 minutes. Compared to placebo, butcher's broom extract significantly decreased venous capacity ($p<0.01$), reduced the blood pool in the lower leg ($p< 0.05$) and reduced tissue volumes in the foot and ankle ($p<0.01$). TMHC did not influence venous capacity and its influence on tissue volume was about 3 times weaker than that of the extract [Rudofsky 1989].

In a double-blind, placebo-controlled study the influence of venous stasis on several microrheological factors and the effects of taking a combination for 30 days were investigated in 25 patients suffering from chronic venous insufficiency (13 verum, 12 placebo). All parameters were also measured in 20 untreated healthy controls. In patients treated with the combination, haematocrit values after stasis did not increase, while they rose in the placebo group. The combination prevented an increase in plasma viscosity after stasis and improved red cell deformability. The red blood cell aggregation index after stasis was similar to that of control subjects, while it increased after stasis in the placebo group [Le Devehat 1991].

Application of 4-6 g of a cream containing 1.6 % of an extract twice daily to the legs of healthy volunteers (n=18) led to constriction of the femoral vein, demonstrated by a decrease in diameter in 8 out of 10 of the verum group by 0.5-3 mm (median=1.25), compared to no change or a dilatation by 0.5 mm (median) in 7 out of 8 of the placebo group (significant between group difference: $p = 0.0139$). In a group of 9 women suffering from pregnancy-related varicosis, application of the preparation to 3 of the women demonstrated that increases in the femoral vein diameter of the painful leg were significantly ($p = 0.047$) lower with treatment with the cream compared to without, and pain in the leg was reduced [Berg 1991].

Clinical studies

Chronic venous insufficiency, varicosis
A meta-analysis of studies using an oral combination to treat chronic venous insufficiency included 20 randomised, placebo-controlled, double blind studies, 5 randomised studies against a positive control, and 6 single arm studies (without placebo) including a total of 10,246 patients. In all studies the response to the preparation was compared to baseline values. On a 4 point symptom severity scale, where 0 corresponds to no symptoms and 3 to severe symptoms, the combination significantly reduced the severity of pain by 0.44 points ($p = 0.02$), cramps by 0.26 ($p = 0.025$), heaviness by 0.53 ($p = 0.001$) and paraesthesia by 0.29 points ($p = 0.031$) compared to placebo. There was also a significant ($p = 0.014$) reduction in venous capacity of 0.7 ml/100 ml with the combination compared to placebo. Non-significant decreases in calf and ankle circumference (0.72 and 1.17 cm respectively) and in the severity of oedema (0.43 points), were found in the treated patients compared to placebo [Boyle 2003].

The efficacy of an orally administered dry extract (15-20:1; methanol 60%) was evaluated in a randomized, double-blind, placebo-controlled study involving 166 women suffering from chronic venous insufficiency (Widmer grades I and II; CEAP 3-4). After a placebo run-in period of 2 weeks, the patients were randomly assigned to either 72-75 mg of the extract or placebo daily for 12 weeks. Data relating to 148 patients (30-89 years, 150-182 cm height, 49-97 kg weight), with mean disease durations of 14.6 years in the extract group ($n = 77$) and 15.1 years in the placebo group ($n = 71$), were eligible for efficacy analysis. Significant differences in favour of the verum treatment were found for reductions in lower leg volume and ankle circumference after 8 and 12 weeks ($p<0.001$), and in leg circumference ($p<0.001$) and the main subjective symptoms ($p<0.05$) after 12 weeks. There was a clear relationship between the changes in lower leg volume and the subjective symptoms "tired, heavy legs", "sensation of tension" and "tingling sensation" ($p<0.05$). Global assessment by the investigators also confirmed the superiority of the extract treatment ($p<0.05$) compared to placebo [Vanscheidt 2002].

In a prospective, multicentre, open clinical study, an oral combination was tested for 8 weeks in 124 patients suffering from chronic venous insufficiency. Initial reports of intensity were 79% for pain, 85% for heaviness, 74% for cramps and 82% for oedema, decreasing within two weeks to 20%, 12%, 8% and 14% respectively. The authors state that symptoms were absent at the end of treatment. Capillaroscopy changes at treatment completion were: 98% to 20% inter-capillary fluid decrease; 80% to 20% efferent loop thickening; 5% to 2% peri-capillary bed, and 5% to 4% mega-capillaries [Aguilar Peralta 2007].

Fifty-two female chronic venous disorder (CVD) patients were allocated consecutively to one of three groups: a combination, elastic compression stockings and no treatment. After 4-weeks treatment, the combination significantly decreased venous diameters (popliteal vein parameters: right $p< 0.04$ and left $p<0.01$) and great saphenous vein diameters (bilaterally $p<0.01$) compared pre-treatment, effects which were comparable to compression stockings [Lascasas Porto 2009].

In an observational, single arm, multicentre, prospective trial, 192 patients suffering from CVD were treated with a combination. Patient profiles, risk factors, clinical symptomatology and quality of life (QoL) assessed by SF-12 and CIVIQ questionnaires were evaluated at inclusion and after 12 weeks of treatment. Clinical symptoms such as feeling of heaviness, pain, swelling of the lower limbs and cramps improved with treatment and ankle circumferences significantly ($p<0.001$) decreased over time. The physical and psychological dimensions of the SF-12 score as well as the CIVIQ score significantly ($p<0.001$) improved over time [Guex 2010].

Haemorrhoids
In observational studies more than 1800 patients (including 26 pregnant women) suffering from haemorrhoids and anorectal complaints have been treated topically with isolated ruscogenins in suppositories (each containing 8 mg) and/or creams (0.8%) for 2 days to 13 weeks. Improvements were reported with respect to symptoms and objective evaluation by the physicians. The efficacy of treatment was estimated as very good or good in 85-93% of cases [Salzmann 1977; Bärmig 1978; Anger 1981].

Retinopathy
In 60 type 2 diabetic patients, oral treatment for 3 months with 37.5 mg of an extract (15-20:1; methanol 60%) twice a day showed an increased amplitude of oscillating potentials by 15% and an increase in visual acuity from 0.83 to 0.93 (not statistically significant results). Furthermore, it led to improvement of the fundus of the eyeball in 23% of the patients (n=20) and prevented progression of retinopathy in all cases [Archimowicz-Cyryłowska 1996].

Pharmacokinetic properties

Pharmacokinetics in animals
The pharmacokinetic characteristics of a radiolabelled extract (not further specified) were investigated in two male Wistar rats. The activity of the extract was 2.8 mCi/mg, with 94% of the total radioactivity bound to saponins. Each animal received 1 mL of extract orally. Radioactivity was detected in the blood 15 minutes after administration. After 2 hours, 39% of the radioactivity was found in the blood samples. After 3.5 hours, in 10 mL samples of blood a maximum radioactivity of 0.41% and 0.45% was observed and was maintained until the end of the 24-hour observation period. The extract was eliminated mainly in the faeces but also renally in a ratio of 2:1, 46% of the administered radioactivity being excreted within 96 hours. Biliary excretion within 24 hours was 8.5 and 10.8% [Chanal 1978].

The bioavailability of a ^{3}H-labelled extract (not further specified) after oral, topical and intravenous administration was studied in rats. Male Wistar rats were treated orally with 1 mL of an aqueous solution containing 0.1 mL of a fluid extract (2% saponins, 70 µCi). Male Atrichi rats were treated topically with 250 mg of a combination of labelled butcher's broom extract, melilotus extract and dextran sulphate, corresponding to 25µCi. By the intravenous route, male Wistar rats received 0.5 mL of an aqueous solution containing 50 mg of the extract (56 µCi). Based on radioactivity in the blood and urine, absorption by the oral route was estimated at 65% and by the local route at 25%. After intravenous administration the existence of an enterohepatic cycle was demonstrated and one-third of the radioactivity was eliminated via the faeces. Following oral administration maximum radioactivity was found in the blood after 2 hours and was maintained for 24 hours. In similar experiments with orally-treated Atrichi rats 80% of the radioactivity was eliminated within 72 hours, with 35% of the dose being detected in the urine [Chanal 1981].

Macaca monkeys (3 females, 3 males) were treated with a tritiated extract (not further specified; 1.5 mCi/kg b.w.) by oral (n = 4) or intravenous (n = 1) routes, or topically in a fixed combination (n = 1). Thin layer chromatography showed that 80-83% of the labelling was fixed in the sapogenin fraction of the extract. Most of the radioactivity was found in the bile, the digestive tract and the urinary tract 2 hours after oral administration, with less in the liver and kidneys. After 7 hours, radioactivity had further increased only in the urinary tract, the bile and the faeces. Radioactivity after 24 hours was markedly lower in all measured tissues. Percutaneous absorption was about 20% compared to absorption after oral administration. Maximum urinary excretion occurred after about 7.5 hours and sapogenins were identified as the major urinary metabolites. A considerable proportion of the radioactivity was excreted in urine (26%, 20% and 4% respectively) and faeces (6.5%, 23% and 9% respectively) within 24 hours after i.v., oral or topical administration [Bernard 1985].

Pharmacokinetics in humans
The presence of butcher's broom saponins in the blood was clearly demonstrated after oral administration of 1 g of butcher's broom extract in three volunteers. Plasma levels of the spirostanol glycosides degluconeoruscin and deglucoruscin were measured by HPLC for 4 hours at 30-minute intervals. The T_{max} for degluconeoruscin was 90-120 minutes after dosing, with a C_{max} of 2.5 µg/mL [Rauwald 1991].

Preclinical safety data

Acute toxicity
The acute toxicity of an ethanolic extract (not further specified) was investigated in dogs and guinea pigs. In 6 male and female dogs death occurred within 1 hour following intravenous infusion of the extract at doses between 0.83 and 1.8 g/kg. By the intraperitoneal route no toxic signs were found in guinea pigs at doses lower than 1.5 g/kg b.w.; animals receiving doses of 2 g/kg b.w. and above died. Toxic and subtoxic doses affected the respiratory function, and lethal doses resulted in hyperventilation followed by fatal apnoea [Moscarella 1953; Caujolle 1953].

Estimation of the oral and intraperitoneal LD_{50} values of a fluid extract (ethanol 50% V/V) in rats and mice revealed differences depending on the harvest time of the plant, the route of administration and the use of roots or rhizomes. The oral LD_{50} of the rhizome extracts was 2.07-2.39 mL/kg b.w. in rats and 24.69-33.73 mL/kg in mice; after intraperitoneal administration the toxicity was 10-20 fold higher. Root extract was found to be more toxic than rhizome extract (1.4-1.8 fold in rats and 4-5 fold in mice). The observed symptoms of intoxication were convulsion, paralysis and gastro-intestinal inflammation with dysentery. Animals died following respiratory failure. Autopsies revealed pronounced irritation of the mucosa and strong visceral congestion [Boucard 1967].

Oral LD_{50} values of ruscogenin and Ruscus saponins were estimated to be greater than 3g/kg b.w. in mice and rats [Capra 1972].

Repeated dose toxicity
An extract (not further specified) was given to male rabbits in their diet for 26 weeks, 17 animals received 2g/kg b.w., 19 received 5g/kg and 16 animals served as controls. Body weights and blood counts did not reveal any differences between treated animals and controls [Roux 1969].

Rats were treated with 300 mg/kg of ruscogenin or *Ruscus* saponins by gavage daily for 8 weeks (10 animals per group, with 10 untreated rats as controls). No toxic signs or differences in body and organ weight were observed. Histological examination did not reveal any pathological changes in any group. Blood glucose and liver function did not differ significantly between the groups. An increase in diuresis and excretion of electrolytes was observed in the ruscogenin group but not in animals treated with saponins [Capra 1972].

Reproductive toxicity
Reproductive toxicity was studied with a combination containing an ethanolic extract (10%), TMHC, citric acid, methyl-4-esculetol

and ascorbic acid; 5 mL of the preparation contained 0.5 mL of the butcher's broom extract. Twenty female Wistar rats received a daily dose of 2.4 mL of the preparation, equivalent to 25 times the recommended dose for humans; 20 untreated animals served as controls. Treatment started one week before conception and continued until delivery. The animals tolerated the drug without any signs of intoxication. The fertility of females in the treatment group was comparable to that in the control group, and the offspring did not show any teratogenic signs [Labie 1984].

Clinical safety data

A dry extract (15-20:1, methanol 60%) taken orally by 77 women at a dosage of 72-75 mg daily for 12 weeks was well tolerated. Overall tolerability was assessed as very good by 76.8% and good by 23.2% of the patients and was comparable to that of placebo treatment. Laboratory data, comparison of vital signs and physical examination before and after treatment did not reveal any treatment-related changes [Vanscheidt 2002].

An early report stated that contact allergy to ruscogenins is a rare adverse effect [Elbadir 1998]. However, this was not confirmed in more recent studies using preparations of ruscogenins, apart from one report of a case of contact dermatitis in a patient using a topical preparation (not further specified) for haemorrhoidal disease. Patch testing revealed positive results for ruscogenins [Ramirez-Hernandez 2006].

In a case report, the development of ketoacidosis in a diabetic patient after consumption of an extract (not further specified) was described. A causal relationship could not be established [Sadarmin 2013].

Combination preparations

Placebo-controlled and open studies with combinations containing butcher's broom extracts have not revealed any specific side effects. Moderate gastric complaints were observed [Monteil-Seurin 1991; Parrodo 1999].

Single cases of diarrhoea and lymphocytic colitis have been reported following the use of combinations containing butcher's broom extract [Beaugerie 1994; Maechel 1992; Rassiat 2001].

In a prospective, multicentre, open study in 124 patients who were treated with a combination containing 300 mg of an extract (not further specified) for 8 weeks, mild headache and vertigo were reported in 24% of the patients during the first week which disappeared in the second week. Mild transient epigastric complaints were reported in 19% of the patients in the fourth week [Aguilar Peralta 2007].

Reproductive toxicity

Ruscogenin-containing suppositories were well tolerated by 30 pregnant women without any apparent effects on the newborn babies [Anger 1981].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

SALICIS CORTEX

Willow Bark

2017

DEFINITION

Willow bark consists of the whole or fragmented dried bark of young branches or whole dried pieces of current year twigs of various species of the genus *Salix* including *S. purpurea* L., *S. daphnoides* Vill. and *S. fragilis* L. The drug contains not less than 1.5 per cent of total salicylic derivatives, expressed as salicin ($C_{13}H_{18}O_7$; M_r 286.3) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Willow Bark].

CONSTITUENTS

The characteristic constituents are derivatives of salicin, mainly salicortin, 2'-*O*-acetylsalicortin and/or tremulacin [Meier 2014]. Young twigs (bark plus wood) contain the same constituents in lower concentrations, when compared to the bark alone. Further constituents, the polyphenols, flavanone and chalcone glycosides, including procyanidins are now also considered to be characteristic of willow bark, as they have been shown to attribute to its beneficial effects [Fiebich 2004; Narstedt2007; Freischmidt 2015].

The bark of *Salix purpurea* L. may contain 6-8.5%, and the bark of *S. fragilis* 4-10%, of total salicin (determined after hydrolysis) [Meier 1985a]. Phenol glucosides present include salicortin (up to 9%), tremulacin (rarely more than 1%) and salireposide (0.1-1.2%), with small amounts of syringin and purpurein (up to 0.4%) [Egloff 1982; Shao 1991; Meier 1985b]. Other constituents include the yellow chalcone isosalipurposide (0.15-2.2%), the flavanones eriodictyol-7-glucoside (0.18-0.4%) and (+)- and (–)-naringenin-5-glucoside (0.4-1.5% each) [Meier 1985b/1988; Freischmidt 2015], approximately 0.5% of (+)-catechin and other polyphenols [Shao 1991], as well as flavan-3-ols and dimeric and trimeric procyanidins [Jürgenliemk 2007; Kaufeld 2014]. Phenolic acids, *p*-hydroxybenzoic, vanillic, cinnamic, *p*-coumaric, ferulic, and caffeic acids were confirmed for the genus of *Salix*. Pyrocatechol (2.25 mg/g) was detected in *S.purpurea* bark [Poblocka 2010]. A lignan, sisymbrifolin, occurred in *S. alba* [Du 2007]. Procyanidin B1 occurs in *S. purpurea* and in *S. alba* clones (0.26-2.24 mg/g) [Poblocka 2008].

The bark of *Salix daphnoides* Villars contains over 4% of total salicin [Meier 1985a]. Phenol glucosides present include salicortin (3-11%), tremulacin (up to 1.5%) and salicin (up to 1%); a small amount of syringin (up to 0.2%) also occurs [Egloff 1982; Julkunen 1989; Shao 1991; Meier 1985b]. Other constituents include the yellow chalcone isosalipurposide (0.2-1.5%), the flavanones (+)- and (–)-naringenin-5-glucoside (0.3-1.0% each) and naringenin-7-glucoside (0.3-1.5%) [Meier 1987/1985b], approximately 0.5% of (+)-catechin and other polyphenols [Shao 1991]. Thirteen characteristic constituents were confirmed in willow bark extracts from commercial products (*S. purpurea x daphnoides*). Picein was only detected in *S. daphnoides* [Kammerer 2005].

CLINICAL PARTICULARS

Therapeutic indications

For the relief of low back pain [Chrubasik 2000a; 2001a; 2001b] and of mild rheumatic conditions [Mayer 1949; Wagner 1995; Schaffner 1997; Meier 1998; Blumenthal 2000; Schmid 2000/2001a; Lardos 2004; Beer 2008; Wichtl 2009; Schilcher 2010].

For the relief of fever associated with common cold and headache [Mayer 1949; Bradley 1992; Wagner 1995; Meier 1998; Kaul 1999; Blumenthal 2000; März 2002; Wichtl 2009; Schilcher 2010]. Efficacy in these indications is plausible on the basis of human experience and long-standing use.

E/S/C/O/P MONOGRAPHS

Posology and method of administration

Dosage
Adult dose, oral use for low back pain and mild rheumatic conditions:
Daily dose of dry hydroalcoholic or aqueous extracts, equivalent to 120-240 mg of total salicin [Schmid 2000/2001a; Chrubasik 2000a; 2001a; 2001b; Lardos 2004; Beer 2008; Wichtl 2009].

Adult dose, oral use for fever, common cold and headache:
Dried bark in decoction, 1-3 g (3-4 times daily);
Liquid extract (1:1, 25% ethanol), 1-3 ml (3-4 times daily);
Tincture (1:5, 25% ethanol), 5-12 ml (3-4 times daily)
[Schaffner 1997; Meier 1998; Blumenthal 2000].

Elderly: dose as for adults.
Children: generally not recommended for children and adolescents under 18 years of age. From age 12 to 17 years the product should not be used without medical advice.

Method of administration
For oral administration.

Duration of use
No restriction. No severe adverse events were reported in investigations of long term treatment with willow bark extracts, including eight clinical studies with a duration of use of 6-8 weeks involving a total of 5871 patients, and a 6 month observational study including 436 patients [Uehleke 2013; Vlachojannis 2014].

Contra-indications
A history of aspirin allergy. In cases of sensitivity to salicylates, the use of willow bark preparations should be avoided [Boullata 2003; Wagner 2003; Clauson 2005; Vasquez 2005].

Special warnings and special precautions for use
The treatment of children with willow bark extracts is not recommended, because of the structural similarity of salicylic derivatives in willow bark to acetylsalicylic acid. The use of synthetic acetylsalicylic acid (aspirin) in children is still associated with the so-called Reye's syndrome, although the number of reported cases appears to be declining with the availability of better diagnostic tools [Clark 2001; McGovern 2001].

Interaction with other medicinal products and other forms of interaction
Following a daily oral dose of willow bark extract, corresponding to 240 mg salicin, patients' platelet aggregation was minimally inhibited, when compared with inhibition by a cardioprotective dose of 100 mg acetylsalicylic acid. Therefore it is possible that willow bark may slightly increase the effects of oral anticoagulants [Krivoy 2001].

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Allergic reactions were attributed to willow bark in 4 patients, including skin rash, swollen eyes and pruritus [Chrubasik 2000a, 2001b].

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties
Recent reviews describe the pharmacological and pharmacokinetic properties of willow bark extracts, and compare the medicinal properties of willow bark with other herbal drugs [Chrubasik 2000b; März 2002; Wagner 2003; Gagnier 2007; Wegener 2009; Vlachojannis 2009].

In vitro experiments

Anti-inflammatory effects and mechanism of action
The hen's egg chorioallantoic membrane test system [Luepke 1985; Luepke 1986] has been used to study the anti-inflammatory effect of the willow bark constituents salicin and tremulacin. Onset of their anti-inflammatory effect is delayed in comparison with saligenin (salicyl alcohol), sodium salicylate and acetylsalicylic acid, indicating that the active principles may be metabolites of salicin and tremulacin [Steineggger 1972].

An extract inhibited LPS-induced COX-2-mediated PGE2 release and weakly inhibited TNFα, IL1β and IL6 release from human monocytes, but had no direct effect on COX-1 or COX-2. The controls, salicin and acetylsalicylic acid, had no effect on any of the parameters [Fiebich 2004].

An extract inhibited LPS-activated monocyte mRNA expression of TNFα, COX-2 and transcription factor NF-kappaB [Bonaterra 2010].

Catechol, a bioactive degradation product of salicortin, reduced TNFα-induced ICAM-1 expression in human endothelial cells [Knuth 2011]. Flavonoids and catechol in a willow bark extract contributed to the reduction of ICAM-1 expression in endothelial cells [Freischmidt 2012].

A purified 2,3-trans procyanidin fraction from willow bark demonstrated redox-sensitive endothelium-dependent relaxation in porcine coronary arteries [Kaufeld 2014].

As flavanone and chalcone glycosides, including procyanidins, in willow bark extracts are considered to contribute to the efficacy of willow bark, as has been demonstrated in various experiments [Fiebich 2004; Narstedt 2007; Vlachojannis 2009; Freischmidt 2012, Kaufeld 2014], a quantitative determination method using hydrolysis of the aglycones, naringenin, eriodictyol and chalconaringenin has been developed for use in willow bark preparations [Freischmidt 2015].

Anti-angiogenesis, apoptotic and cytotoxic activity
In endothelial cells (ECV304) treated with salicin (2-5mM) for 24h, migratory properties were reduced, tubular formation was inhibited and the mRNA expression of vascular endothelial growth factor (VEGF) was decreased. Angiogenesis was suppressed by blocking the reactive oxygen species production and extracellular signal-regulated kinase (ROS-ERK) activation. This indicates that salicin significantly inhibits angiogenic activities of endothelial cells [Kong 2014]. Flavonoids, proanthocyanidins (GI50 at 33-103 µg/ml) and salicyl alcohols (GI50 at 50-243 µg/ml) in willow bark extract fractions, inhibited cancer cell growth and promoted apoptosis of human colon and lung cancer cell lines [Hostanska 2007].

In vivo experiments

Anti-inflammatory effects
Isolated tremulacin, injected subcutaneously at 100 mg/kg b.w., significantly inhibited carrageenan-induced paw oedema ($p<0.001$ in hours 3-6 after carrageenan injection) and peritoneal

leucocyte migration (by 50%, p<0.01) in rats, and croton oil-induced ear oedema (by 43%, p<0.001) and acetic-acid induced writhing (p<0.01 to p<0.001) in mice. Inhibition of leukotriene B_4 biosynthesis in pleural leucocytes (obtained *ex vivo* from rats 4 hours after intra-pleural injection of carrageenan) also supported the activity of tremulacin in acute inflammatory animal models [Cheng 1994].

In the rat 6d air pouch model, a willow bark extract showed a significant increase of reduced glutathione (GSH) levels, *in vitro* and *in vivo*. It also raised superoxide dismutase activity. The extract was more potent than acetylsalicylic acid or celecoxib [Khayyal 2005].

The contribution of polyphenols and flavonoids to the mechanism of action and overall effect of aqueous extracts of *S. purpurea* and *S. daphnoides* has been shown. However, *in vivo* and *in vitro* studies suggest that the clinical efficacy of willow bark cannot be entirely explained by the total salicin fraction alone [Narstedt 2007].

Antipyretic effects
Salicin administered orally to rats at 5 mmol/kg b.w. significantly reduced yeast-induced fever, producing a normal temperature, and completely preventing fever when administered simultaneously with yeast. However, salicin at this dose level did not affect the rectal body temperature of afebrile rats. On the other hand, both sodium salicylate and saligenin at 5 mmol/kg lowered body temperature significantly in afebrile rats [Akao 2002].

Antitumour activity, inhibition of tumour angiogenesis and apoptosis
In a mouse model, salicin at 10 mg/kg/day i.p. significantly inhibited tumour growth. Angiogenesis during tumour growth was reduced by the salicin treatment, as measured by two markers, the level of haemoglobin and the expression of CD31 on endothelial cells. This indicates that salicin might inhibit tumour progression by reducing angiogenesis within the tumour [Kong 2014].

Pharmacological studies in humans

Platelet aggregation
In a randomized, placebo-controlled, double-blind study, patients with acute exacerbations of chronic low back pain were treated with either oral willow bark extract corresponding to 240 mg of salicin (n = 19) or placebo (n = 16) daily for 28 days; a third group of patients suffering from chronic ischaemic heart disease (n = 16) received 100 mg of acetylsalicylic acid daily during the study period. Arachidonic acid-induced platelet aggregation, measured in blood samples drawn from the patients after 28 days of treatment, was minimally inhibited by the willow bark extract, but significantly less when compared to the inhibition by acetylsalicylic acid. The mean percentages of maximal arachidonic acid-induced platelet aggregation were 61%, 78% and 13% in the willow bark extract, placebo and acetylsalicylic acid groups respectively [Krivoy 2001].

Clinical Studies

Controlled studies
In a randomized, double-blind, placebo-controlled pilot study, a total of 21 patients with degenerative rheumatic conditions were treated daily for 14 days, either with a standardized extract of willow bark (n = 11, 240 mg salicin/d) or with placebo (n = 10). Pain intensity was decreased in 8/10 patients in the willow bark group and in 5/10 patients in the placebo group. No severe adverse reactions were reported in 10 of 11 patients receiving willow bark; 1 patient dropped out due to stomach ache, which appeared to be unrelated to taking the preparation. A similar number of slight adverse events (tiredness, stomach ache, head ache) were reported in both groups [Schaffner 1997].

A standardized willow bark extract in coated tablets was evaluated in patients with osteoarthritis in a randomized, double-blind, placebo-controlled study at an oral dosage corresponding to 240 mg of salicin (n = 39) or placebo (n = 39) daily for 2 weeks following a washout phase with placebo for 4-6 days. Efficacy was assessed by means of the WOMAC Osteoarthritis Index. The WOMAC pain score in the willow bark group decreased significantly (-14%, p<0.047) compared to that of the placebo group (+ 2%). The final overall assessments showed significant superiority of the willow bark extract over placebo (physicians' assessment, p=0.0073; patients' assessment, p=0.0002) and demonstrated a moderate analgesic effect in osteoarthritis [Schmid 2000 / 2001a].

In a randomized, double-blind, placebo-controlled, three-arm study, patients with an exacerbation of chronic low back pain were assigned to one of three treatments: a standardized willow bark extract in coated tablets corresponding to either 2 × 120 mg of salicin (n = 70) or 2 × 60 mg of salicin (n = 70), or placebo (n = 70), daily for 4 weeks. Efficacy was assessed using the Arhus Low Back Pain Index, and the opioid analgesic tramadol was the sole rescue medication. From intention-to-treat analysis, the number of pain-free patients without rescue medication (responders) in the last week of the study was significantly higher (p<0.001) in the verum groups and also dose-dependent: 27 out of 70 (39%) in the 240 mg group and 15 out of 70 (21%) in the 120 mg group, compared to 4 out of 70 (6%) in the placebo group. Significantly more patients in the placebo group required tramadol (p<0.001) during each week of the study. Willow bark extract thus appeared to be a useful and safe treatment for low back pain [Chrubasik 2000a].

Two randomized, placebo-controlled clinical trials, one in hip or knee osteoarthritis and the other in active rheumatoid arthritis, were conducted for 6 weeks, comparing a standardized willow bark extract (240 mg salicin/d), with placebo, and in one of the studies also with diclofenac. Neither study found significant efficacy for willow bark extract when compared with placebo. However, as was expected, the difference between placebo and diclofenac was highly significant (p=0.0002) [Biegert 2004].

In a randomized, double-blind, parallel group trial, the efficacy and tolerability of 2 doses of willow bark extract (90 or 180 mg salicin/d) were compared to diclofenac sodium (150 mg/d) for 3 weeks in patients with knee or hip osteoarthritis. No other NSAIDs were allowed. Analgesic activity and pain intensity of both groups treated with the extract were statistically comparable to that of the diclofenac sodium group. Tolerance of the extract was considered as good [Lardos 2004].

Open studies
An older, open, uncontrolled clinical study for various acute and chronic rheumatic conditions and respiratory tract infections (n = unknown), reported anti-rheumatic, anti-neuralgic and anti-pyretic activity in 70% of the treated cases [Mayer 1949].

In an open, randomized, controlled, post-marketing study, patients with acute exacerbations of low back pain were assigned to treatment with a willow bark extract (corresponding to 240 mg of salicin, n = 114) or the synthetic anti-rheumatic rofecoxib, a selective COX-2 inhibitor (12.5 mg, n = 114) daily for 4 weeks. All patients were free to use additional conventional treatments if necessary. About 20 patients were pain-free (visual analogue

Table 1. Summary of clinical studies with willow bark extract

Lit. reference First Author Year	Clinical study design ** No. patients n = verum: placebo: positive control	Diagnosis	Verum medication Placebo and/or Reference therapy Duration of treatment	Outcome Safety
Controlled studies				
Schaffner 1997	Pilot study R / D-B / P-C n = 11:10	Painful arthritis (degenerative disease)	Extract (240 mg salicin/d) 2 weeks	*n.s. Better pain reduction for the extract ADE: 30:30
Schmid 2000/2001a	R / D-B / P-C n = 39:39	Osteoarthritis	Extract (240 mg salicin/d) 2 weeks	*** Sign. decrease of WOMAC-score ($p<0.047$)
Chrubasik 2000a	R / D-B / P-C n = 70:70:70	Exacerbation of chronic lower back pain	Extract (120 mg salicin/d) Extract (240 mg salicin/d) Placebo 4 weeks Rescue medication, tramadol, allowed for all groups.	*** Sign. Number of responders to the extract requiring no rescue medication was significantly higher than with placebo ($p<0.001$). Sign. more use of tramadol in the placebo-group ($p<0.001$).
Biegert 2004 (first trial)	R / D-B / P-C / P-R-C n = 43:43:41	Cox- or gonarthrosis (hip or knee)	Extract (240 mg salicin/d) Diclofenac (100 mg/d) Placebo 6 weeks	*n.s. decrease of WOMAC score for extract vs. placebo. Significant for diclofenac vs. placebo ($p=0.0002$).

* n.s. = data for willow bark are not significant;
** R = randomized; D-B = double-blind; P-C = placebo-controlled; P-R-C = positive-reference-controlled; C = controlled.
*** Sign. = data for willow bark are significantly better than placebo or comparable to a positive reference.
ADE = Adverse drug event; sign. = significant; pos. ref. = positive reference drug.

scale score < 2) in each group after 4 weeks of treatment. About 60% of patients in each group responded well to treatment, as judged by improvement of ≥ 30% in the Total Pain Index. Only a few patients resorted to additional conventional treatment options. The incidence of adverse events was similar in the two groups and there was no significant difference in efficacy between willow bark extract and rofecoxib [Chrubasik 2001a].

In an open, non-randomized, controlled post-marketing study, groups of patients with acute exacerbations of low back pain received willow bark extract corresponding to either 120 mg (n = 115) or 240 mg (n = 112) of salicin daily or, as controls, no treatment with willow bark (n = 224). All patients had access to conventional treatments according to the budget of the general practitioner. Better pain relief and less reliance on supplementary conventional treatments was evident in the group treated with 240 mg of salicin, compared to the group treated with 120 mg. A cost reduction of 14-40% was reported for the willow bark groups [Chrubasik 2001b].

An open, multi-centre, observational study was conducted in patients with gonarthrosis and coxarthrosis. They were treated for 6 weeks with a standardized willow bark extract (dose equivalent to 120-240 mg salicin/d; n=88) or with standard reference medications (n=40; positive control). The WOMAC score was used for evaluation. Willow bark treatment was comparable to that of standard therapies in mild or fairly severe cases of gonarthrosis and coxarthrosis, and had fewer side effects [Beer 2008]. Further open, uncontrolled studies [Werner 2004; Saller 2008; Uehleke 2013], are presented in table 1.

Pharmacokinetic properties

Pharmacokinetics in vitro

Hydrolysis of salicin
Salicin was stable under acidic conditions (0.5% hydrochloric acid, with or without pepsin) and produced no saligenin (salicyl alcohol), even after incubation with human saliva at pH 7.2 [Steinegger 1972; Fötsch 1989a].

Hydrolysis of salicortin
Salicortin was unchanged after 1 hour of incubation in artificial gastric juice (pH 1.0). After 6 hours of incubation with artificial intestinal juice (pH 7.4-7.6 at 37°C) salicortin was degraded to salicin at $t_{0.5}$ = 4.02 hours [Meier 1987; Meier 1990].

Enzymatic hydrolysis and esterification
Both β-glucosidase extracted from almonds (EC 3.2.1.21) and β-glucosidase derived from guinea pig liver, converted salicin and salicortin to saligenin [Julkunen 1992; Gopalan 1992]. However, salicin derivatives acetylated on the sugar moiety (2'-*O*-acetylsalicin and 2'-*O*-acetylsalicortin) and tremulacin were not decomposed by β-glucosidase. Non-specific esterases (EC 3.1.1.1) from rabbit and porcine liver transformed salicortin to salicin (98.1%), acetylsalicortin to acetylsalicin (75.5%) and tremulacin to tremuloidin (63.9%) [Julkunen 1992]. Pancreatic proteases degraded salicortin to salicin and tremulacin to tremuloidin [Wutzke 1991].

Erythrocyte membrane permeability and protein binding
Transport of salicin and saligenin into erythrocytes was rapid for saligenin (1 minute to saturation) and delayed for salicin (4 hours to saturation). The process was reversible, release being rapid for saligenin and slower for salicin. Saligenin and salicin both bind to human serum albumin but saligenin has a significantly higher affinity [Matsumoto 1993].

Metabolic transformation by homogenized kidney, liver and lung
Saligenin was transformed into salicylic acid by homogenized liver, kidney and lung. Gentisic acid was qualitatively detectable in homogenized liver after incubation with saligenin [Fötsch 1989a]. Salicin was partially metabolised to saligenin and salicylic acid after incubation with homogenized kidney from rats [Adamkiewicz 1961].

Intestinal metabolism
Salicin injected into an isolated, closed-off section of the male rat intestine, appendix and colon was hydrolysed by intestinal bacteria to its main metabolite saligenin [Fötsch 1989b].

Transport through intestinal wall
Transport of salicin and saligenin through the isolated intestinal wall was confirmed using the closed-off posterior section of the male rat intestine. When salicin and saligenin were injected into the closed intestine, both passed the ileum wall unchanged. Saligenin appeared to penetrate the intestinal wall faster than salicin [Adamkiewicz 1961].

Pharmacokinetics in animals

Serum concentration-time curve and metabolism in rats
After oral administration of salicin to 4 male Wistar rats at 1 mmol/kg (0.268 g/kg) the urinary metabolites were: unchanged salicin (ca. 15% of the dose), saligenin (ca. 0.1%), salicylic acid (ca. 30%), conjugated salicylic acid (ca. 5%) and gentisic acid (ca. 2%). After oral administration of a total of 2.5 g of salicin in successive daily doses of 1 mmol/kg, only unchanged salicin was identified in the faeces [Fötsch 1989a].

The concentration of the metabolite salicylic acid was determined in the serum of rats after oral administration of salicin (400 mg/kg) or sodium salicylate (29 mg/kg). With salicin, no salicylic acid appeared during the first 2 hours but then it appeared in the serum, gradually increased and peaked at 5 hours with C_{max} = 82.4 µg/ml. After administration of sodium salicylate, salicylic acid appeared rapidly and reached a maximum concentration at 1.5 hours with C_{max} = 104.2 µg/ml. Elimination was slower after administration of sodium salicylate than after salicin. The relative bioavailability of salicylic acid from salicin was only 3.25% of that from sodium salicylate [Fötsch 1990].

Plasma levels of salicin, saligenin and salicylic acid were measured and compared to sodium salicylate after oral administration of each compound to rats at 1, 2.5 and 5 mmol/kg. Salicin appeared to be a prodrug, which was gradually transported to the lower part of the intestine, hydrolysed to saligenin by intestinal bacteria and converted to salicylic acid after absorption. Salicin absorption is slow compared to that of saligenin or salicylic acid [Akao 2002].

In rats administered 100 mg/kg of oral salicortin, catechol and salicylic acid were detected in serum, after serum processing with metabolizing enzymes. The predominant metabolite was catechol sulfate. Unconjugated catechol could not be detected [Knuth 2013].

Metabolism of radioactively-labelled salicin in mice
^{14}C-labelled salicin (8.9 mg/mouse) was rapidly and completely metabolised after oral administration to mice. Free salicylic acid was detected in the blood. Elimination was mainly by the renal route. Salicortin (4 mg/mouse) and tremulacin (11 mg/mouse) were partially metabolised. The metabolite gentisic acid was transiently detected in the small intestine [Wutzke 1991].

Pharmacokinetics in humans

Absorption, distribution, metabolism and elimination
Salicin (4.0 g, corresponding to 1730 mg of saligenin) and, in a separate experiment, 2.0 g of sodium salicylate were taken as self-medication by the investigator to study and compare the kinetics. The maximum plasma concentration of free salicylates was reached about 2 hours after administration of salicin with C_{max} = 100 µg/ml. In comparison, sodium salicylate yielded C_{max} = 150 µg/ml, also after about 2 hours. Metabolites equivalent to more than 86% of the administered salicin were recovered in 24-hour urine: salicyluric acid (51%), salicyl glucuronide (14%), salicylic acid (12%), gentisic acid (5%) and saligenin (4%), together with a small amount of unchanged salicin [Steinegger 1972]. The urinary metabolite spectrum of oral acetylsalicylic acid in man [Dinnendahl 1982] is very similar to that of salicin taken orally [Meier 1990]. Populin (6'-*O*-benzoyl salicin) is not metabolised after oral administration in man [Steinegger 1972].

Absorption and metabolism of willow bark extract
Twelve male volunteers took 3 tablets containing willow bark extract (standardized to provide a total dose of 55 mg salicin) and cola nut extract. The plasma C_{max} of salicylic acid was 130 ng/ml, reached 3 hours after administration, and the plasma half-life was calculated as 2.5 hours. An exceptional increase in the plasma level of salicylic acid observed in one volunteer 4-6 hours after administration was attributed to the effects of eating lunch during this period. Administration of a second dose of 3 tablets four hours after the first dose produced a C_{max} of 311 ng/ml six hours after the first dose. This level was not increased further by a third dose of 3 tablets eight hours after the first dose [Pentz 1989].

A standardized willow bark extract preparation corresponding to 240 mg of salicin was administered to 10 healthy volunteers in two equal doses at 0 and 3 hours. Urine and serum collected over a 24-hour period showed that salicylic acid was the major metabolite in serum (86% of total salicylates). Peak levels of salicylic acid were reached after 2 hours (1.2 mg/L) and the area under the curve (AUC) was equivalent to that expected from an intake of 87 mg of acetylsalicylic acid. From this study it was concluded that willow bark extract leads to much lower serum salicylate levels than observed after analgesic doses of synthetic salicylates. The formation of salicylic acid alone does not therefore explain the analgesic or anti-rheumatic effects of willow bark [Schmid 2001b].

Quantities of gentisic, salicyluric and salicylic acids found in human plasma, from persons not taking aspirin drugs, were assumed to be derived from vegetarian food containing salicylic acid-derived compounds, such as can be found in cucumber, melon, cherry and others [Pirker 2004].

Eight healthy volunteers received a single oral dose of 4 tablets of willow bark extract, corresponding to 240 mg salicin (2 controls did not receive willow bark). Catechol and salicylic acid were detected in serum, after processing with the metabolizing enzymes glucuronidase and sulphatase. The predominant metabolite was catechol sulfate. Unconjugated catechol did not occur in serum [Knuth 2013].

Preclinical safety data

Acute toxicity
A hydroethanolic (30%) willow bark extract, administered to mice, yielded an LD_{50} of 28 ml/kg. With a dry extract of willow bark the LD_{50} could not be reached [Leslie 1978; März 2002].

Repeated dose, chronic and reproductive toxicity
A hydroethanolic (30%) extract of willow bark (35% of a combination product, including primula root extract and a plasmolysate of *Candida utilis*) was administered by gavage to rats for 13 weeks, at a dose of 1.6 ml/kg. No adverse events were reported during this period, and there was no negative effect on reproduction in female rats. Teratogenic effects were not observed in rabbits during this period [Leslie 1979; März 2002].

Mutagenicity and carcinogenicity
No data available.

Induction of gastric lesions
Oral administration of salicin did not induce gastric lesions in rats even at a dose of 5 mmol/kg. However, saligenin and sodium salicylate did induce severe gastric lesions in a dose-dependent manner in the range of 1-5 mmol/kg [Akao 2002].

Prediction of adverse events
Using an *in vivo* screening tool in rats (gene expression profiling) to predict possible adverse events due to herbal medicinal products containing salicylates and the antidepressant imipramine, it was found that imipramine crossed the threshold level for adverse events several times, whereas the willow

bark extract reached the threshold level only once [Ulrich-Merzenich 2012].

Clinical safety data
In studies involving 6993 patients and healthy volunteers treated with various preparations containing willow bark extracts, only mild adverse events were reported [Mayer 1949; Pentz 1989; Schaffner 1997; Krivoy 2001; Schmid 2000/2001a; Chrubasik 2000a; 2001a; 2001b; Biegert 2004; Lardos 2004; Werner 2004; Beer 2008; Saller 2008; Knuth 2013; Uehleke 2013].

No significant adverse reactions were reported in 10 out of 11 patients treated daily for 14 days with a standardized extract of willow bark (240 mg salicin/d). One patient dropped out due to stomach ache, which appeared to be unrelated to taking the preparation [Schaffner 1997].

In a 2-week randomized study involving osteoarthritis patients, the number of patients experiencing adverse events was the same in the placebo group (16 out of 39) as in those treated with willow bark extract corresponding to 240 mg of salicin per day (16 out of 39). However, more adverse events were reported in the placebo group (28) than in the verum group (17), the most frequent being allergic skin reactions and gastrointestinal upsets. The most important adverse event in the verum group was a skin rash starting on day 10, however the patient did have a medical history of frequent allergic reactions [Schmid 2000; 2001a].

In a 4-week randomized, three-arm study in patients with low back pain (three groups of 70), an allergic reaction (skin rash, swollen eyes, pruritus) reported by 1 patient receiving low-dose willow bark extract (equivalent to 2 × 60 mg of salicin / d) was attributed to the extract; dizziness reported by 2 patients taking the extract at the higher dose (2 × 120 mg of salicin/d) was attributed to tramadol rescue medication. In the placebo group, 3 patients reported dizziness and other symptoms attributed to tramadol, and 3 reported mild gastrointestinal ailments [Chrubasik 2000a].

In 227 patients treated with willow bark extract (corresponding to 120 or 240 mg of salicin daily), occasional mild adverse events occurred as well as 3 cases of allergy which could be attributed to the willow bark [Chrubasik 2001b].

During a 2-day treatment of 12 male volunteers with 12 tablets, containing a combination of willow bark extract (166.6 mg, standardized to 11% total salicin) and a dry extract of cola nut (38 mg, standardized to 25% caffeine), no adverse events were reported [Pentz 1989].

In a 2-month double-blind placebo-controlled study involving 41 patients with chronic arthritic pain, treated daily with 2 tablets of a combination product containing 200 mg of powdered willow bark and four other herbs, 3 adverse events were reported, that could not be directly related to willow bark: one of dyspeptic symptoms, one of diarrhoea and one of headache [Mills 1996].

An extensive review of willow bark studies supported the hypothesis that the extract is less prone to cause adverse reactions in the stomach than are known to be caused by acetylsalicylic acid. This appears to be because willow bark does not inhibit cyclooxygenase in the stomach wall, since its active metabolites are generated in the intestine after passing through the stomach as intact glycosides; the development of stomach lesions is therefore unlikely [Kaul 1999; März 2002]. Another review of the safety of willow bark extract treatments concluded that the incidence of adverse effects is low [Chrubasik 2000b].

Peak levels of salicylic acid in the serum of 10 healthy volunteers who received a willow bark extract corresponding to 240 mg of salicin per day were approximately 1.4 mg/L. In contrast, peak levels of 35-50 mg/L have been reported after the intake of 500 mg of acetylsalicylic acid. Therefore, the observed analgesic effect of willow bark may not be attributed to salicylic acid alone. It can be postulated that other constituents (e.g. polyphenols, tannins, flavonoids, salicin, salicin esters or others) may contribute to the overall effects of willow bark [Schmid 2000/2001a; Narstedt 2007]; and it may consequently be considered to have a broader mechanism of action and to be safer, than aspirin [Chrubasik 2000a; Akao 2002; Fiebich 2005; Clauson 2005; Narstedt 2007; Vlachojannis 2011].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein

SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

SALVIAE FOLIUM

2020

Sage Leaf

DEFINITION

Sage leaf consists of the whole or cut dried leaves of *Salvia officinalis* L. The whole drug contains not less than 12 mL/kg of essential oil and the cut drug not less than 10 mL/kg of essential oil, both calculated with reference to the anhydrous drug.

The material complies with the monograph of the European Pharmacopoeia [European Pharmacopoeia].

Fresh material may also be used, provided that when dried it complies with the monograph of the European Pharmacopoeia.

CONSTITUENTS

Essential oil, up to 2.5% [Sticher 2015], containing monoterpenes such as α- and β-thujone (up to 63% and 13%, respectively), camphor, 1,8-cineol, borneol and manool [Müller 1992; Lawrence 1998; Nicolella 2014]. Monoterpene glycosides [Croteau 1984; van den Dries 1989]. Diterpenoids such as carnosic acid and its derivatives, e.g. carnosol [Brieskorn 1969; Rutherford 1992], and a quinone methide [Tada 1997]. Triterpenoids including ursolic acid, oleanolic acid and their derivatives [Brieskorn 1980,1991]. Flavonoids, e.g. hispidulin, 5-methoxysalvigenin [Brieskorn 1971,1979; Kavvadias 2003]. Phenolic compounds, e.g. rosmarinic acid and derivatives [Gracza 1984; Lu 1999a], a caffeic acid trimer [Lu 1999b], and flavonoid and phenolic glycosides [Lu 2000; Wang 1999,2000].

CLINICAL PARTICULARS

Therapeutic Indications

Dyspeptic complaints such as heartburn and bloating [Schilcher 2016; Blaschek 2016], hyperhidrosis [Rösing 1989; Brieskorn 1991; Weiss 2000; Blaschek 2016], hot flushes [Bommer 2011], supportive treatment of hyperglycaemia and hyperlipidaemia [Sà 2009; Kianbakht 2011, 2013, 2016].
Inflammations and infections of the mouth and throat such as stomatitis, gingivitis and pharyngitis [Brieskorn 1991; Weiss 2000; Hubbert 2006].

Posology and method of administration

Dosage

Oral use

Dyspeptic complaints
1 - 2.5 g cut herbal drug as an infusion, up to 3 times daily [Van Hellemont 1988, Bradley 2006; Schilcher 2010; Blaschek 2016].

Liquid extract (ethanol 50%, 1:4-5) 30 drops 3-5 times daily or liquid extract (ethanol 96%, 1:4-6) 10-15 drops several times daily [Schilcher 2016].

Hyperhidrosis
2 - 4.5 g cut herbal drug as a cooled tea in the evening [Rösing 1989; Blaschek 2016].

Dried aqueous extract (4-7:1) 80 – 160 mg 3 times daily after a meal. For treatment of nocturnal sweating 160 – 320 mg before bedtime [Rösing 1989; Schilcher 2016].

Hot Flushes
Thujone-free soft extract 280 mg (equivalent to 3400 mg tincture of fresh leaves, DER 1:17) once daily [Bommer 2011].

E/S/C/O/P MONOGRAPHS

Supportive treatment of hyperglycaemia and hyperlipidaemia
4 g cut herbal drug twice daily as an infusion [Sà 2009].
Dry extract (4:1; ethanol 80%) 500 mg 3 times daily [Kianbakht 2011, 2013, 2016].

Topical use

Inflammation of the mouth or throat
2.5 – 3 g cut herbal drug as an infusion for a mouthwash or gargle 3 times daily [Van Hellemont 1988; Blaschek 2016; Schilcher 2016].

Extract (1:1, ethanol 70%) as a spray 3 times daily [Hubbert 2006].

Extract (1:4-5; ethanol 50%): 1-2 teaspoons in 150 mL warm water, gargle for 1 minute every 2 hours [Schilcher 2016].

Extract (1:4-6; ethanol 96%): dilute ½ teaspoon in 150 mL warm water, gargle several times daily [Schilcher 2016].

1% hydroethanolic mouthwash applied for 60 seconds twice daily [Behesthi-Rouy 2015].

Method of administration
For oral administration or topical application.

Duration of administration
If the symptoms persist or worsen, medical advice should be sought. In hyperhidrosis, treatment for 2-4 weeks, using an aqueous preparation, is recommended [Rösing 1989].

Contra-indications
None known.

Special warnings and special precautions for use
The daily dose of 6.0 mg thujone should not be exceeded [EMA 2012].

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
Due to the potential toxicity of some constituents of the essential oil [von Skramlik 1959; Pinto-Scognamiglio 1967; Gessner 1974; Millet 1979], the use of sage leaf is not recommended during pregnancy or lactation.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No effects are to be expected at a daily dose up to 6.0 mg thujone [EMA 2012].

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antimicrobial effects
An extract enriched in diterpene phenols (35% w/w) was tested against various aerobic bacteria and Candida species in an agar dilution test. The extract had an effect against *Corynebacterium pseudodiptheric*um (MIC = 10 µg/mL, MBC = 20 µg/mL) and *B. subtilis* (MIC = 20 µg/mL, MBC = 20 µg/mL). Carnosic acid was effective against *C. pseudodiphtericum* (MIC = 32 µg/mL, MBC = 128 µg/mL) and *S. aureus* (MIC = 64 µg/mL, MBC = 64 µg/mL) [Weckesser 2006].

An extract (acetone 70%, not further specified) showed activity against vancomycin-resistant Enterococci. Oleanolic acid and ursolic acid were identified as the active compounds with MICs of 8 and 4 µg/mL respectively. The MICs against MRSA were 32 and 16 µg/mL respectively, and against *S. pneumoniae* 16 and 8 µg/mL respectively. There was no effect against gram negative bacteria such as *S. marcescens* [Horiuchi 2007].

The anti-herpetic effect of extracts (ethanol 20, 40, 60 or 80% V/V) of plants from two different locations was investigated in RC-37 cells (African green monkey kidney cells). Either cells were pretreated with extracts before viral infections, or viruses were treated with extracts before cell infection, or the extract was applied after the virus had penetrated the cell. All extracts showed a high virucidal activity against HSV-1 and 2 as measured by plaque reduction. The extracts of the sample of origin 1 resulted in dose-dependent IC_{50} values ranging from 0.03-7.5 µg/mL for HSV-1 and 0.02 to 0.75 µg/ml for HSV-2, the extracts of the sample of origin 2 from 0.12-11.18µg/mL for HSV-1 and 0.21-3.20 µg/mL for HSV-2. The antiviral activity of extracts prepared with higher ethanol concentrations was more pronounced. Pretreatment of HSV-1 and 2 with the extracts also reduced plaque formation. The extracts were not able to reduce plaque formation in cells already infected with the virus [Schnitzler 2008].

The antibacterial activities of two dilutions (1:25 and 1:100) of an extract (1:2, ethanol 60%) were examined on *Helicobacter pylori* and *Campylobacter jejuni*. Both dilutions showed >99% inhibition of bacterial growth for both species at both concentrations [Cwikla 2010].

The activity of different extracts and synergistic effects with antibiotics were tested against *Staphylococcus aureus*, *Escherichia coli*, *Pseudomonas aeruginosa*, *Bacillus subtilis*, *Enterobacter cloacae*, *Klebsiella pneumoniae* and *Proteus mirabilis*. An acetone dry extract from 30 g leaves was most effective with MIC values between 0.019 mg/mL and 1.25 mg/mL. The combination with amoxicillin showed a higher synergistic capacity in comparison to a combination with chloramphenicol. This was shown by an increased activity from 2- to 10-fold depending on bacterial strain (mean fractional inhibitory concentration FIC 0.35 to 1.37) [Stefanovic 2012].

A dried extract (80% methanol) showed significant ($p<0.001$) inhibitory effects against leishmanial promastigotes (IC_{50} =184.32 µg/mL) and amastigotes. A 60% lethality of parasites internalised in macrophages was shown [Nikmehr 2014].

Sage oil exhibited bactericidal and fungicidal properties against Gram-positive and Gram-negative bacteria, filamentous fungi and yeasts, e.g. *Candida albicans* [Jalsenjak 1987; Janssen 1989]. An aqueous and a 50%-ethanolic extract of sage leaf exhibited strong inhibitory effects on the collagenolytic activity of *Porphyromonas gingivalis* [Osawa 1991]. Aerial parts of sage contain diterpenes with activity against vesicular stomatitis virus [Tada 1990; Chiba 1992; Tada 1994].

The essential oil exhibited activity against *E. coli*, *B. subtilis*, *Micrococcus luteus*, *S. aureus*, *P. aeruginosa*, *Enterobacter aerogenes*, *K. pneumoniae* and *Salmonella spp.* The undiluted oil showed the strongest effects against *M. luteus* and *E. aerogenes*.

Dilutions of the oil (1/2, 1/5, 1/10, 1/20 and 1/100) were less effective, indicating a dose-dependent effect [Fadil 2015].

Synergistic effects of the essential oils of young and old leaves with the antibiotics ceftriaxone, ciprofloxacin and gentamicin against MRSA were assessed. The essential oil of young leaves intensified the antibiotic activity of ceftriaxone and ciprofloxacin more than the oil of old leaves [Milenkovic 2015].

The effect of the essential oil in 50% ethanol (V/V) at a final concentration of 10 mg/mL was examined on six fungal strains (*Aspergillus niger*, *Aspergillus flavus*, *Botrytis cinerea*, *Rhizoctonia solani*, *Fusarium oxysporum*, and *Alternaria alternata*), using amphotericin B (20 µg/well) as a positive control. *Fusarium oxysporum* was the most sensitive strain with an MIC value of 0.156 mg/mL [Khedher 2017].

The essential oil reduced biofilm formation of *Streptococcus pyogenes* in a concentration-dependent manner, significant ($p \leq 0.05$) for all strains at 0.5 mg/mL. Growth inhibition of *S. pyogenes* resulted in an MIC of 0.5 mg/mL [Wijesundara 2018].

Antioxidant effects
A 50%-methanolic extract from aerial parts of sage considerably inhibited lipid peroxidation in both enzyme-dependent and enzyme-independent test systems [Hohmann 1999; Zupkó 2001].

The effects of an extract (85% ethanol, not further specified) on the antioxidant system including CAT, SOD, GST and GSH were investigated by determining the reduction capability on the DPPH radical. The extract (3, 10, 30, 100 and 300 µg) prevented the increase of GST, SOD and CAT, but did not prevent a decrease in GSH levels [Mayer 2009].

An aqueous and an 80% methanolic extract, at concentrations of 0.5 and 0.033% respectively, showed significant ($p<0.05$) antioxidant activity including free radical scavenging activity, reducing power, β-carotene bleaching inhibition and lipid peroxidation inhibition in brain cell homogenates. The methanolic extract exhibited greater activity than the aqueous extract [Martins 2015].

Anti-inflammatory effects
The anti-inflammatory effect of a dried ethyl acetate extract (94 g drug/600 mL; containing 4.3 % carnosol, 20.1% carnosic acid) was investigated in a cell-free mPGES-1 activity assay. Carnosol and carnosic acid were the main active constituents in inhibiting mPGES-1. Carnosol did not show any effect in LPS-stimulated human whole blood, while carnosic acid (1, 3 and 30 µM) inhibited PGE_2 formation (IC_{50} = 9.3 µM). The formation of 6-keto $PGF_{1\alpha}$, 12-HHT, PGH_2 and thromboxane B_2 was not affected [Bauer 2012].

Sage infusion (1.5 g dried leaves/150 mL), fractions thereof (aqueous distillate and non-volatile dry matter) as well as several isolated compounds (at concentrations corresponding to the infusion) were examined for their anti-inflammatory effects using human gingival fibroblasts. A significant ($p<0.05$) inhibition of PMA/I-induced IL-8 and IL-6 release was demonstrated for the infusion (99.2 ± 0.1% and 98.5 ± 0.1% respectively) as well as for the fractions. A significant ($p<0.05$) more than 50% mean inhibition of both IL-8 and IL-6 release was demonstrated for 1,8-cineole, borneol, camphor and thujone [Ehrnhöfer-Ressler 2013].

Carnosic acid dose-dependently (2.5-20 µM) suppressed the LPS-induced inflammatory response in RAW264.7 macrophages and reduced the LPS-elicited overexpression through restraining transcript levels and gene expression of Nos2, TNF-α, COX2 and monocyte chemotactic protein (MCP-1). It was shown by western blot analysis that carnosic acid downregulates the MAPK pathway by blocking the phosphorylation of ERK ½, JNK and p38. LPS-induced IKKβ/IκB-α/NF-κB pathway activation was also inhibited by carnosic acid, based on decreasing phosphorylation of IKKβ, IκB-α and NF-κB p65 subunit and hence preventing nuclear translocation. Carnosic acid suppressed the FoxO pathway by blocking the nuclear translocation of FoxO1 and 3 in a concentration-dependent (5-20 µM) manner. The FoxO pathway regulates pro-inflammatory genes and mediators such as IL6, TNF-α and MCP-1 [Wang 2018].

Antigenotoxic effects
An extract (ethanol 40%) inhibited H_2O_2- and 2,3-dimethoxy-1,4-naphthoquinone (DMNQ)-induced DNA damage in HepG2 cells at concentrations of 0.01-100 mg/mL. Concentrations of 1 and 2 mg/mL significantly ($p<0.001$) decreased the damage, assessed as the amount of DNA strand breaks. The extract significantly ($p<0.001$) increased GPx, decreased SOD and had no effect on iGSH [Kozics 2013].

Two extracts (ethanol 95%, yield 1.73%; and acetone 75%, yield 3.87%) showed dose- and time-dependent inhibitory effects on the viability of HepG2 cells and WRL-68 cells. The ethanolic extract exhibited a higher activity towards HepG2 cells and provoked a significant ($p<0.001$) increase in LDH at 50 and 150 µg/mL, significantly ($p<0.001$) decreased ATP in a dose-dependent manner and changed the morphology of HepG2 cells [Jiang 2017].

Hypoglycaemic effects
Carnosol and carnosic acid, as well as an extract (ethanol 80%, DER 1:10), selectively activated Gal4-PPARγ fusion receptor in a concentration-dependent manner (EC_{50} = 41.2 ± 5.9µM, 19.6 ± 2.0µM and 33.7 ± 7.3mg/L, respectively). PPARα and δ were not affected [Rau 2006].

Several compounds were tested for PPARγ-activating properties at three concentrations (0.1, 1.0, 10 µM). Carnosol, carnosic acid, oleanolic acid, α-linolenic acid and 12-O-methyl carnosic acid at 10 µM provoked PPARγ-activation. 20-hydroxyferruginol did not activate PPARγ [Christensen 2010].

Other effects
The influence of a dried ethanol extract (55.8 mg/mL) on the activity of CYP2D6 was investigated by measuring the reaction rate of dextromethorphan-O-demethylation from dextromethorphan to dextrorphan at concentrations of 815, 81.5 and 8.15 µg/mL in the incubation medium. The extract resulted in an inhibition of CYP2D6 with an IC_{50} of 800 µg/mL [Hellum 2007].

Reaction mixtures containing 300 µg of gastric vesicular protein, 1 mM ATP, 20 mM $MgCl_2$ and 50mM Tris-HCl (pH 7.4) with and without hydroethanolic extract (0.03, 0.1 and 0.3 mg/mL) were used for colorimetric determination of the release of inorganic phosphate from ATP as an indicator for ATPase activity, with 0.2 mg/mL omeprazole as positive control. An extract (85% ethanol) inhibited the activity of the ATPase by 46-66% and dose-dependently showed higher results than omeprazole (49%) [Mayer 2009].

An extract (ethanol 70%, not further specified) inhibited angiogenesis in HUVEC and rat aorta models at 300 µg/mL and higher concentrations, it also induced wound repair by endothelial cells at 100-200 µg/mL in a dose-dependent manner. The hexane fraction showed an angiogenesis-inhibiting activity at concentrations above 50 µg/mL (HUVEC) and 50-100 µg/mL (wound repair) [Keshavarz 2010].

In isolated tracheal preparations, a dry extract (methanol 70%, yield 15%) at 1-10 mg/kg dose-dependently inhibited K^+ (25 mM)-induced contractions. Pretreatment of the tissues with 4-aminopyridine reversed the inhibitory effect of the extract against K^+, whereas glibenclamide did not show any effect. When tested against carbachol-induced pre-contractions the extract showed a dose-dependent (0.03-0.1 mg/mL) inhibitory effect and shifted the inhibitory concentration response curves of isoprenaline to the left, similar to that of papaverine [Gilani 2015].

Cells from twelve immature female mice were grown to measure the oestradiol and progesterone concentration under the influence of varioust concentrations (0, 10, 50, 100, 500 and 1000 mg/mL) of an extract (70% ethanol, yield 17%) using radioimmunoassay (RIA) for oestradiol and immunoradiometric assays (IRMA) for progesterone determination. Oestradiol and progesterone concentrations, as well as ALP activity, increased significantly ($p<0.001$) at high concentrations (500 and 100 mg/mL) of the extract. The *in vitro* maturation of oocytes (obtained from 25-35 days old Balb/C female mice after i.p. injection of 17 IU pregnant mare serum gonadotropin and 17 IU human chorionic gonadotropin) was investigated in seven experimental groups with various extract concentrations (5, 10, 50, 100, 250, 500 and 1000 mg/mL) and one control group. Cell viability assays showed that at higher concentrations the percentage of living cells decreased. At 500 and 1000 mg/mL of extract the amount of granulosa cells was reduced significantly ($p=0.02$, $p=0.01$, respectively), while at a concentration of 100 mg/mL of the extract the cell cultures showed an early stage of apoptosis. Lower doses had no effect on the growth of granulosa cells or on function and maturation of oocytes [Monsefi 2017].

An aqueous extract (not further specified) demonstrated a cytoprotective and renoprotective effect against CCl_4-induced nephrotoxicity using Vero cells in an MTT and biosensor assay. After extract exposure, the LC_{50} of CCl_4 increased from 6.06 mM to 8.08 mM [Flampouri 2017].

The essential oil showed cytoprotective activity against UMSCC1 cells with an IC_{50} of 135 µg/mL [Sertel 2011].

The effects of isolated phenolic diterpenes on melanin biosynthesis in B16 melanoma cell lines as well as on AChE were examined. Isorosmanol showed a melanin-inhibiting activity comparable to arbutin. At 500 µM, 7α-methoxyrosmanol and isorosmanol inhibited AChE activity by 50% and 65% respectively [Sallam 2016].

In vivo experiments

Antinociceptive and anti-inflammatory effects

Topical application of various extracts (n-hexane, chloroform, methanol) and essential oil were investigated in Croton oil-induced ear oedema in mice. Chloroform extracts exhibited the strongest effect (ID_{50} = 105.9 µg), followed by n-hexane extracts (ID_{50} = 683.2 µg). The methanolic extract had a weaker effect (ID_{50} > 1000 µg). The essential oil showed no effect. The anti-inflammatory activity of ursolic acid, the main component of the chloroform extract, was evaluated in comparison to oleanolic acid and indomethacin. The oedema-inhibiting effect of ursolic acid was in a comparable range with indomethacin and higher than oleanolic acid [Baricevic 2001].

A tincture (ethanol 70%, 1:10) adminstered intraperitoneally to male rats (no information on dosage) showed anti-inflammatory effects on acute inflammation induced by turpentine oil. The tincture reduced total leukocyte count, differential leukocyte count ($p<0.0001$) and nitrite levels ($p<0.05$) [Oniga 2007].

An aqueous extract (yield 15%; 10, 31.6, 100, 316, 1000 mg/kg) and a butanol fraction (10, 31.6, 100, 316 mg/kg) demonstrated analgesic effects in rats after i.p. administration in the hot-plate and the formalin-induced paw licking tests. The effect was inhibited by the opioid-receptor-antagonist naloxone (5 mg/kg). The extract and the fraction exhibited dose-dependent anti-inflammatory activity by reducing the degree of swelling in carrageenan-induced paw oedema as well as of cotton pellet granuloma. The butanol fraction (ED_{50} 29 ± 4 mg/kg) showed greater activity than the aqueous extract (ED_{50} 90 ± 5 mg/kg) [Qnais 2010].

In the acetic acid model in mice, an extract (ethanol 85%, not further specified) at doses of 10, 30 and 100 mg/kg b.w. p.o. reduced writhing, total leukocytes and plasma extravasation. Mice treated orally with the extract, carnosol (10 mg/kg b.w.), ursolic or oleanolic acid (each 30 mg/kg b.w.) one hour before formalin injection, exhibited a reduction of neurogenic and inflammatory responses. Pretreatment with naloxone (1 mg) reversed the antinociceptive effect of the extract at 100 mg/kg. Administration of the extract one hour before injection of glutamate into the paw reduced oedema and demonstrated antinociceptive activity at each dose [Rodrigues 2012].

The effects of an extract (approx. 20:1; ethanol 80%) on nociception and on prevention of morphine-induced tolerance and dependence were studied in rats using the tail-flick and naloxone precipitation withdrawal tests. Intragastric (i.g.) administration of 600 and 800 mg/kg of extract exhibited a significantly ($p<0.001$) greater antinociceptive effect than vehicle alone, while 400 mg/kg demonstrated a non-significant benefit. Morphine tolerance and dependence respectively were induced by injection of morphine (10 mg/kg, s.c.) twice a day for 7 days or escalating doses of morphine (2.5 mg/kg s.c. on days 1 and 2, followed by an increased dose each day up to 5, 10, 20, 40 and 50 mg/kg) twice daily for 7 days, followed by administration of naloxone (3 mg/kg s.c.) after the last injection of morphine on day 7. The extract was given at doses of 400, 600 or 800 mg/kg i.g. 30 minutes before each dose of morphine in both experiments. The highest dose of extract prevented development of significant tolerance to the antinociceptive activity of morphine while the lowest dose did not. In the morphine dependence experiment, the extract at 600 and 800 mg/kg attenuated most of the naloxone-induced withdrawal signs including weight loss, jumping, penis licking, teeth chattering, wet dog shakes, rearing, standing, sniffing, face grooming and paw tremor and increased sleep duration. Furthermore, the extract at the highest dose significantly ($p<0.001$) increased pentobarbital-induced sleeping time and decreased sleep latency ($p<0.05$) [Hasanein 2015].

The effects of an extract (5:1, ethanol 80%; 100 and 200 mg/kg, p.o.) as well as rosmarinic acid (10 and 20 mg/kg, i.p.) and caffeic acids (30 and 40 mg/kg, i.p.) on peripheral neuropathic pain after chronic constriction injury were investigated in mice. These substances, as well as clomipramine (5 mg/kg, i.p.) as positive control, were administered on days 0, 1, 7, 14 and 21 following surgery. All treatments significantly ($p<0.05$) increased mechanical sensitivity, cold and thermal withdrawal latency ($p<0.001$) and enhanced functional recovery of the injured sciatic nerve. The same treatments ameliorated haematological parameters and did not alter biochemical levels. Histopathological findings revealed a protective effect of the extract, rosmarinic acid and caffeic acids against the induced damage [El Gabbas 2019].

Larvicidal effect

An extract (ethanol 80%, yield 12.3 ± 1.2%) demonstrated larvicidal activity against *Culex pipiens*, transmitting diseases

like Japanese encephalitis and Yellow fever, resulting in an LC_{50}, LC_{90} and LC_{100} of 287, 487 and 600 ppm respectively [Abdelhakim 2016].

Hypoglycaemic effects
In streptozotocin-induced diabetic rats, administration of a methanolic extract (1:5; 100, 250, 400 and 500 mg/kg b.w., i.p.) produced a slight decrease in serum glucose. No effect was observed in healthy fasted rats [Eidi 2005].

Oral administration of an ethanolic extract (1:5, yield 16%; 0.1, 0.2 and 0.4 g/kg) for 14 days demonstrated a hypoglycaemic effect and also significantly ($p<0.001$) reduced triglycerides, total cholesterol, urea, uric acid, creatinine, AST and ALT in streptozotocin-induced diabetic rats as compared to 600 µg/kg glibenclamide [Eidi 2009].

An extract (methanol 80%, yield: 23%; 250 mg/kg p.o. for 21 days) showed an increase in SOD activity (33%) as well as a decrease in triglycerides (40%, $p<0.0001$), LDL- (30%, $p<0.001$) and VLDL cholesterol (22%, $p<0.001$) in alloxan-induced diabetic rats [Sani 2012].

The effects of an extract (ethanol 80%, 1:10) on learning and memory in streptozocin-induced diabetic rats, as well as on the antioxidant capability and hypoglycaemic properties, were evaluated after administration of 400, 600 and 800 mg/kg p.o. for 30 days. In the passive avoidance learning test the higher doses (600 and 800 mg/kg) improved learning and memory deficits in diabetic rats and also cognition of healthy rats. Significant hypoglycaemic activity ($p<0.001$), lipid peroxidation inhibition and enhanced activity of antioxidant enzymes such as SOD ($p<0.05$) and catalase ($p<0.05$) were observed [Hasanein 2016].

Obese mice (n=32; on a high fat diet) were treated for five weeks with a high (400 mg/kg/day) or a low (100 mg/kg/day) dose of an extract (methanol 80%, not further specified). An oral glucose tolerance test (OGTT) resulted in significantly lowered blood glucose levels 30 minutes after the glucose load ($p<0.05$ and $p<0.001$ after high and low doses respectively). The effect was similar to that of rosiglitazone (3 mg/kg/day; positive control). Insulin sensitivity improved, as demonstrated by a reduction in fasting plasma insulin levels and a reduced insulin sensitivity index by 39% and 60% respectively. The low dose significantly decreased concentrations of plasma insulin, triglycerides and non-esterified fatty acid levels ($p<0.05$). Anti-inflammatory cytokines (IL-2, IL-4 and IL-10) increased ($p=0.003$, $p=0.036$, $p=0.006$, respectively), while pro-inflammatory cytokines (TNF-α, KC/GRO and IL-12) decreased ($p=0.030$, $p=0.004$, $p=0.034$, respectively) [Khedher 2018].

Lipid-lowering effects
The inhibitory effect of single doses of a methanolic extract (yield: 30.4%; 500 and1000 mg/kg p.o.), carnosol (200 mg/kg) and carnosic acid (5, 10 and 20 mg/kg) on serum triglyceride elevation was investigated in olive oil-loaded mice. The extract significantly ($p<0.01$) suppressed triglyceride elevation at both doses. Carnosic acid exhibited an effect equivalent to that of the pancreatic lipase inhibitor orlistat, while carnisol had no significant effect. Carnosic acid was subsequently administered to mice on a high fat diet at 5, 10 and 20 mg/kg/day p.o. for 14 days. Carnosic acid at 20 mg/kg significantly ($p<0.05$) reduced body weight gain compared to the high fat diet control mice and at all doses significantly ($p<0.01$) suppressed the increase of the epididymal fat pad [Ninomiya 2004].

The effects of the essential oil and simvastatin were studied in hyperlipidaemic mice. Animals were randomly divided into four groups which received a standard diet (control), a high fat diet or a high fat diet combined either with simvastatin (2.5 mg/kg b.w./day) or with the essential oil (4 mg/kg b.w./day) for 8 weeks. The essential oil and simvastatin reduced body weight gain, hyperlipidaemia, disruption of liver and renal functions and reactive oxygen species production in mice on the high-fat diet. Total cholesterol, triglycerides, total lipids and LDL cholesterol levels as well as aspartate transaminase, alanine transaminase, GGTP and LDH activities were reduced, while faecal lipids increased compared to those of high fat diet only mice. The reductions in triglycerides, LDL and VLDL were significantly ($p<0.01$) greater for the essential oil than simvastatin [Koubaa-Ghorbel 2020].

Gastroprotective effects
The gastroprotective effect of 30, 100, 300 and 1000 mg/kg of an extract (85% ethanol) was investigated in rats. Omeprazole (40 mg/kg) was used as positive control. Gastric lesions were induced by oral administration of 0.5 ml 80% ethanol per animal one hour after the administration of the test substances. The extract decreased the area of gastric lesions in a dose-dependent manner, with an ED_{50} of 84.0 mg/kg.

Acetic acid (20%) was used to induce chronic gastric ulcers in a further group of rats. Seven days after the induction procedure, rats were treated orally for a further 7 days with either vehicle, 20 mg/kg omeprazole or 10, 30 or 100 mg/kg of the extract. The extract dose-dependently reduced ulcer volume by 59, 66 and 76% respectively, as compared to 75% by omeprazole.

In a futher group of rats, either vehicle (control), 40 mg/kg omeprazole or 300, 600 or 1000 mg/kg of the extract were administered after pylorus ligature, 4 h later the rats were killed and gastric secretions collected. The extract at the highest dose reduced the volume of gastric juice from 6.4 to 3.2 mL ($p<0.001$) and the total acidity [mEq[H^+]/L] from 47.9 to 13.7 ($p<0.001$) compared to control, while omeprazole decreased the volume to 4.9 mL ($p<0.05$) and the total acidity to 15.6 mEq[H^+]/L ($p<0.001$) [Mayer 2009].

Memory-improving effects
An ethanolic extract (1:5; 80% ethanol; 5, 10, 50, 100 mg/kg i.p.) demonstrated significantly ($p<0.001$) increased memory retention in rats in a passive avoidance test. The extract at 50 mg/kg significantly ($p<0.0001$) potentiated the memory retaining effects of nicotine and pilocarpine. While the the nicotinic receptor antagonist mecamylamine and the muscarinic receptor antagonist scopolamine significantly ($p<0.0001$) attenuated the response [Eidi 2006].

Antimutagenic effects
Acute (24h), chronic (48h) and two combined treatments (one acute, one chronic) with an infusion (15 mg/mL; 200mL) and/or the mutagen MMS were analysed in the somatic mutation and recombination test on *Drosophila melanogaster*. The infusion reduced the frequency of mutations indicated by a decreased number of large, small, single and twin spots on the chapped wings of D. melanogaster but did not lower the mutagenic effect to the level of spontaneous mutagenesis [Patenkovic 2009].

The chemoprotective properties of an aqueous extract (13.3 g/L boiling water) were investigated in 3-week-old rats. Azoxymethane (AOM; 15 mg/kg) was used as a mutagen. Two groups received the extract with their drinking water for two weeks before the administration of AOM or vehicle, two groups for 4 weeks after the application of AOM or vehicle, two control groups received water and water+AOM respectively. The extract significantly ($p<0.05$) decreased the number of aberrant crypt foci when administered two weeks before AOM but showed no effect when applied for 4 weeks after AOM [Pedro 2016].

Oral treatment of mice with 1 mg/kg of mitomycin C followed

by 25, 50 or 100 µL/kg of the essential oil resulted in a dose-dependent decrease of aberrations induced by mitomycin C. The concentrations of 25 and 50 µL/kg significantly ($p<0.001$) reduced the frequency of metaphases [Vujosevic 2004].

Wound healing effects
Topical application of a hydroethanolic extract (150 g leaves/600 mL; 1, 3 and 5% in an ointment consisting of 25% eucerin and 75% vaseline) demonstrated wound healing properties in rats. Wound contraction was significantly ($p<0.05$) and dose-dependently increased on days 12, 15, 18 and 21 as compared to placebo and untreated controls. Duration of re-epithelialisation ($p<0.05$), new vessel formation and fibroblast distribution ($p<0.05$) were significantly improved [Karimzadeh 2017].

Antioxidative effects
An extract (ethanol 40%) increased the resistance to oxidative stress and reduced H_2O_2- and 2,3-dimethoxy-1,4-naphthoquinone-generated DNA damage in liver cells of rats. Administration of 3.33, 6.67 and 13.33 mg/kg p.o. for 14 days provoked a significant increase in glutathione peroxidase (GPx) ($p<0.05$, $p<0.01$ and $p<0.001$ respectively) and in GSH ($p=0.01$) in rat hepatocytes. A change in SOD activity was not observed [Horváthová 2016].

To investigate the effect of an aqueous extract (not further specified) on bleomycin-induced lung fibrosis, male Wistar rats were given a single dose of bleomycin (4 mg/kg, intratracheal) followed by the extract (50, 100 and 150 mg/kg, i.p.) 3 days later for 4 weeks. The extract at 150 mg/kg normalized increased lipid peroxidation and decreased SOD as well as CAT levels. The fibrosis score was significantly decreased by the extract at 100 mg/kg (2.8 ± 0.34 vs. 3.9 ± 0.3; $p<0.05$) and 150 mg/kg (1.9 ± 0.27 vs. 3.9 ± 0.3; $p<0.01$) as compared to the bleomycin group [Bahri 2019].

Antiulcerogenic effects
Male Wistars rats were treated with 50, 75, 100 or 150 µg/kg b.w. of an ethanolic extract or received distilled water or omeprazole (30 mg/kg) one hour before ulcer induction with ethanol. The total area of lesion (mm^2) was significantly reduced to 109.14, 35.25, 29.66 and 29.55 in all groups receiving the extract (all $p<0.05$) compared to negative control (151.4) and omeprazole (50.76). All extract doses and omeprazole reduced the ulcerative lesion index significantly ($p<0.05$ or <0.001 respectively). Omeprazole ($p<0.01$) and the extract at doses of 50 µg/kg and 75 µg/kg (both $p<0.05$) as well as at 100 µg/kg and 150 µg/kg (both $p<0.001$) led to a significant increase in the curative ratio [Fiorentin 2013].

Other effects
The locomotor activity of mice assessed in an open-field test was not affected by single oral doses of 10, 30 and 100 mg/kg of an ethanolic extract (85% ethanol, not further specified) [Rodrigues 2012].

A dry extract (methanol 70%, yield 15%) at 1-10 mg/kg dose-dependently inhibited carbachol-induced bronchospasms in anaesthetized rats with three-fold greater potency than aminophylline at 3-30 mg/kg [Gilani 2015].

The essential oil and thujone (89.5% α- and 10.5% β-thujone) were examined in the light/dark (L/D) test in rats providing an estimation of the degree of animal anxiety. Thujone at 5, 10 and 25 mg/kg b.w. as well as the oil at 10, 25 and 50 mg/kg b.w. significantly ($p<0.001$) increased the time that the animals spent in the illuminated part of the apparatus and the number of transitions between the light and dark compartments, in a similar manner to diazepam (2 mg/kg b.w.). Diazepam-induced sleeping time was significantly ($p<0.001$) prolonged by the higher doses of thujone and of the oil [Radulović 2017].

α- or β-thujone (78 nmol injected intracerebrally) affected the open field behaviour of three-day old chicks, inducing anxiogenic behaviour as shown by the reduction of locomotor activity and an increase in latency. Moreover, α-thujone eliminated the stress-induced flunitrazepam sensitive $GABA_A$-receptor recruitment [Rivera 2014].

Pharmacological studies in humans
In a randomized, placebo-controlled, double-blind, five-period crossover study, the effects of a dried ethanolic extract (7.5:1; ethanol 70%) on cognitive performance in twenty healthy adults (65 to 90 years, mean age 72.95) were assessed using the Cognitive Drug Research computerised assessment battery. Volunteers attended six laboratory visits, one practice session and five subsequent visits when they received a single dose each of either placebo or extract at 167, 333, 666 and 1332 mg with a 7 day washout period between each visit. Cognitive performance was assessed before each treatment and at 1, 2.5, 4 and 6 h post treatment. Secondary memory performance was significantly enhanced by the extract at 333 mg at all testing sessions, by the 167 mg dose at 2.5 and 4 h and by the 1332 mg dose only at 4h compared to placebo. Accuracy of attention was significantly improved by the 333 mg dose at 1, 4 and 6h and by the two highest doses at 4h, when compared to placebo. There were no significant effects on speed of memory and speed of attention. Working memory was significantly improved at 1h with the 333 mg dose [Scholey 2008].

A non-randomized crossover trial with six healthy female volunteers (40-50 years) for four weeks showed that consumption of a tea (4 g leaves/300 mL twice a day) improved lipid profiles and antioxidant defences. LDL cholesterol and TC levels decreased by 12.4% and 5.4% respectively, while HDL values increased by 50.6%. An increase in SOD and CAT activities indicated antioxidant activity. Hsp72, an endogenous stress modulator, was increased (its reduction correlates with reduced insulin sensitivity in type 2 diabetes) [Sà 2009].

Clinical studies

Antihidrotic effects
In an open study, patients with idiopathic hyperhidrosis were treated daily for 4 weeks with either 440 mg of a dry aqueous extract corresponding to 2.6 g of leaf (n=40) or an infusion from 4.5 g of leaf (n=40). The achieved reduction in sweat secretion (less than 50%) was comparable in the two groups, although slightly greater in the group treated with extract [Rösing 1989].

Antimicrobial and anti-inflammatory effects
A randomized, double-blind, placebo-controlled, parallel group study with adaptive two-stage design and interim analysis assessed the efficacy and tolerability of a spray containing an extract (1:1, ethanol 70%) in patients with pharyngitis (n=82 per group). Throat pain intensity was evaluated using a VAS before treatment and at intervals of 15 minutes for the first 2 hours after the first spray application. The treatments continued with two more applications on treatment day one, three applications on day two and the last application on day three in the morning before the final visit. The patients took three puffs (140 µl/puff) per single application. Significant ($p<0.001$) pain reduction was observed in the verum group as compared to placebo [Hubbert 2006].

In a randomized, double-blind, placebo controlled clinical trial, the antibacterial activity of a 5% mouthwash (0.5 g ethanolic extract (48%) in 100 ml distilled water) against *Streptococcus*

mutans in dental plaque was investigated in 70 female children (11-14 years, n=35 per group) for three weeks. In the verum group (rinsing for 60 seconds twice a day, with continued usual oral hygiene measures) a significant (p=0.001) reduction in colony count from 3900 to 600 units was observed. The use of placebo mouthwash resulted in a non-signficant decrease from 4071 to 3174 colonies only [Beheshti-Rouy 2015].

In a controlled trial, patients (aged 20 to 40 years) suffering from minor aphthous ulceration (n=15) or gingivitis (n=15) applied a mouthwash (1 tsp of dried herb steeped for 20 mins in 1 cup of boiling water) for 60 seconds twice daily for 6 days, while the control group (n =15 for both complaints) used a saline mouthwash. Gingival index scores decreased from 2.05±0.5 to 0.82±0.2 ($p<0.05$) in the sage group and from 2.02±0.7 to 1.35±0.6 ($p<0.05$) in the saline group after 6 days. The patients with aphthous ulceration underwent observation of the ulcer on days 1, 3 and 6. Significant reduction in pain intensity (p=0.001 to p=0.005) was observed in the sage group, and complete healing of ulceration was seen in three patients (p=0.02) on day 6 after treatment with the sage mouthwash [Fawzi 2017].

Hypoglycaemic and lipid-lowering properties
The efficacy of 500 mg of an extract (yield 23%; not further specified) given three times daily for two months was investigated in a randomized, double-blind, placebo-controlled study including female and male patients with newly diagnosed primary hyperlipidaemia (hypercholesterolaemia, hypertriglyceridaemia or both, triglyceride and/or total cholesterol levels between 240-300 mg/dL). The extract (n=34) significantly lowered blood levels of TC (19.6%, $p<0.001$), triglycerides (22.8%, $p<0.001$), LDL (19.7%, p=0.004) and VLDL (13.3%, p=0.001) and increased HDL (20.2%, p=0.001) as compared to placebo (n=33), but had no significant effect on SGOT, SGPT and creatinine [Kianbakht 2011].

In a randomised, double-blind, placebo-controlled study, 80 type II diabetic patients who had not reached ideal control of the disease received either tablets containing 150 mg of an extract (not further specified) or placebo three times daily day for three months. Fasting blood sugar and 2-hours postprandial glucose levels were checked at the beginning and every two weeks. Glycosylated haemoglobin (HbA1c), lipid profile, liver and kidney function were tested at the beginning and at the end of the trial. After 12 weeks, the 2-hours postprandial glucose levels were significantly ($p<0.05$) decreased from 222.0 ± 58.4 mg/dL to 174.5 ± 21.0 mg/dL in the verum group compared to a decrease from 214.6 ± 42.8 mg/dL to 207.7 ± 49.2 mg/dL in the placebo group. The fasting blood sugar levels decreased from 144.2 ± 43.6 mg/dL to 115.0 ± 45.9 mg/dL in the verum group and from 142.9 ± 34.7 mg/dL to 143.4 ±39.5 mg/dL in the placebo group. No differences were observed in any other parameters [Behradmanesh 2013].

In a randomized, triple-blind, placebo-controlled trial, type 2 diabetic patients aged 40 to 60 years (fasting glucose 150-200 mg/dL, HbA1c 7-9%, LDL 100-150 mg/dL, triglycerides 200-300 mg/dL; medication: 2 x 5 mg glyburide and 2 x 500 mg metformin per day), received additional treatment with either placebo (n=40) or 500 mg of an extract (4:1, ethanol 80%; n=40) 3 times a day for 3 months. The extract signficantly (all $p<0.05$) lowered levels of fasting glucose (25.8%), HbA1c (14.4%), total cholesterol (17.7%), triglycerides (32.2%) and LDL (19.2%) and increased HDL (34.8%) when compared to placebo [Kianbakht 2013].

In a randomized, double-blind, placebo-controlled clinical trial including hypercholesterolaemic type 2 diabetes patients (n=50 per group; 40 to 60 years, HbA1c < 8%, LDL 100-130 mg/dL; medication: 15 mg glyburide, 2000 mg metformin and 10 mg atorvastatin), the effects of 500 mg extract (4:1; ethanol 80%) three times a day as add-on therapy for two weeks were evaluated. Fasting glucose, 2 h postprandial glucose, HbA1c, TC, LDL and triglycerides decreased, while HDL increased, when compared to placebo ($p<0.05$) [Kianbakht 2016].

Effect on postmenopausal symptoms
The effect of an extract on postmenopausal women (n=69; aged 50 to 65 years (mean age 56.4 ± 4.7), at least 12 months since last menstruation) experiencing at least five flushes daily was investigated in an open, multicentre trial using the Menopause Rating Scale (MRS), the change in intensity and frequency of hot flushes and the total score of the mean number of intensity rated hot flushes (TSIRHF). Each patient received 280 mg thujone-free spissum extract (equivalent to 3400 mg tincture of fresh leaves, DER 1:17) daily for 8 weeks, to be taken before their strongest flush of the day. The TSIRHF decreased significantly (p=0.0001) from 9.3±12.2 to 4.8±3.6 (48%) after 4 weeks, and to 3.8±3.5 (64%) after 8 weeks. The mean number of mild, moderate, severe and very severe flushes showed reductions of 46% ($p>0.05$), 62% (p=0.0001), 79% (p=0.0001) and 100% ($p<0.05$) respectively at week 8. The mean global MRS score and all subscales decreased: MRS (43%, $p<0.0001$), somato-vegetative subscale (43%, $p<0.0001$), psychological subscale (47%, $p<0.0001$) and urogenital subscale (20%, $p<0.01$). A positive effect was seen for MRS symptoms such as heart discomfort, irritability, anxiety, physical and mental exhaustion, joint and muscular discomfort and especially hot flushes and sleep problems [Bommer 2011].

In a randomized, double-blind, placebo-controlled trial postmenopausal women with hot flushes and nocturnal sweating (n=50 per group) received 3 x 100 mg sage tablets (not further specified) per day or placebo for 8 weeks. Menopasual symptoms were evaluated using the MRS 1 week before treatment and after 8 weeks, while duration, frequency and intensity of hot flushes and night sweats were evaluated every week during the trial. The mean duration of hot flushes in the verum group (3.6±1.6 at baseline), declined each week and was reduced to 1.4±0.7 at week eight ($p<0.001$). The mean number of hot flushes significantly ($p<0.001$) decreased from 5.7±2.6 to 2.3±0.8 in the verum group at the end of the intervention, and the mean severity of hot flushes from 2.35 to 1, with the latter remaining almost unchanged in the placebo group. The number of nocturnal sweats was significantly ($p<0.001$) reduced in the verum group. The MRS total score was significantly ($p<0.001$) reduced by 25% after eight weeksin the verum group. No significant differences were observed between the groups with regard to oestradiol levels, although the verum group's oestradiol levels did significantly (p=0.014) increase [Forouhari 2016].

In a randomized, double-blind, placebo-controlled clinical trial, 66 postmenopausal women suffering from menopausal symptoms received either 300 mg extract (not further specified) daily for 3 months or placebo. Menopause Rating Scale (MRS) and Pittsburgh Sleep Quality Index (PSQI) questionnaires were completed at the beginning and at the end of the study. The checklists for hot flushes and night sweats were completed at weeks 0, 2, 4, 6, 8, 10 and 12. In the verum group, the mean score of flushing, palpitation, sleeping disorders, muscle and joint aches, depression, nervousness, anxiety and sexual desire and satisfaction significantly decreased by 1.6, 0.4, 1.6, 2.1, 1.4, 1.2, 1.6, and 0.8 units, respectively, in the verum group compared to the placebo group ($p<0.001$). The mean score of PSQI significantly ($p<0.05$) decreased by 3.8 units in the verum group (9.4 ± 3.7 vs 5.6 ± 1.9) while no change was observed in the placebo group (Zeidabadi 2020).

Effects on premenstrual syndrome
In a randomized, triple-blind, placebo-controlled clinical trial, 110 women aged 18 to 35 years with premenstrual syndrome (PMS) received either 500 mg of an extract (20:1; ethanol 96%; n=47) or placebo (n=43) daily from day 21 of their cycle until day 4 of the next cycle, for two consecutive months. Data were collected from 90 subjects who completed the study, using a demographic and menstrual cycle history questionnaire as well as a reporting form for daily PMS symptoms, containing a checklist of 20 physical items as well as mood and behavioural symptoms. The severity of symptoms decreased significantly ($p<0.001$) in the verum group during the first and second month of treatment by 19.8% and 23.4% respectively. Physical symptoms of PMS such as breast tenderness, oedema, bloating and fatigue as well as psychological symptoms including tension, irritability and depressive mood also decreased significantly ($p<0.001$) in the verum group compared to placebo [Abdnezhad 2019].

Effects on cognition
The effect of an extract (ethanol 45%, 1:1) on the cognition of patients with mild to moderate Alzheimer's disease was examined in a randomized, double-blind, placebo-controlled trial involving forty patients aged between 65 and 80 years with a score of ≥12 on the cognitive subscale of Alzheimer's Disease Assessment Scale (ADAS-cog) and ≤2 on the Clinical Dementia Rating (CDR). Each patient was given 60 drops/day of the extract or placebo for 16 weeks. The ADAS-cog ($p<0.0001$) and CDR ($p<0.0001$) values were significantly improved compared to placebo after 16 weeks. Patients in the placebo group showed increased agitation compared to verum [Akhondzadeh 2003].

Pharmacokinetic properties

Absorption
In single-dose toxicokinetic studies in rats and mice, α-thujone was rapidly absorbed without any species or sex difference and rapidly distributed into tissues including the brain. Females showed a higher brain-plasma ratio and had a higher sensitivity to thujone-induced toxicity [NTP 2011, Waidyanatha 2013].

Metabolism
α-Thujone incubated with rabbit liver cytosol in the presence of NADPH gave thujol and neothujol in low yield. On incubation with mouse liver cytosol alone, α-thujone was stable, but in the presence of NADPH it was rapidly metabolized, the major product being 7-hydroxy-α-thujone together with 4-hydroxy-α-thujone, 4-hydroxy-β-thujone and other minor metabolites [Höld 2000].

In mice treated intraperitoneally with α-thujone, the brain levels of α-thujone and 7-hydroxy-α-thujone were dose- and time-dependent, but α-thujone appeared at much lower levels and was less persistent than 7-hydroxy-α-thujone [Höld 2000].

Human liver microsomes produced two major (7- and 4-hydroxy-thujone) and two minor (2-hydroxy-thujone and carvacrol) metabolites. Glutathione and cysteine conjugates were detected in human liver homogenates. No glucuronide or sulphate conjugates were detected. Major hydroxylations accounted for more than 90% of the primary microsomal metabolism of α-thujone [Abass 2011].

After consumption of 900 mL of an infusion from 6 g sage (containing 0.64 mg/L α-thujone corresponding to 4.6–14.3 µg/kg b.w.), the α-thujone metabolites 2-hydroxythujone, 4-hydroxythujone and 7-hydroxythujone were found in the urine. After consumption of 575 µg α-thujone, 4-hydroxythujone and 7-hydroxythujone were detected in the urine of the volunteers. 2-Hydroxythujone was not detected in any of the samples. α-Thujone was found in a low amount, with a maximum concentration of 94 ng/L for the volunteer with the highest dose of 14.3 µg/kg b.w. [Thamm et al 2018].

Bioavailability
After single administration by gavage of 25 mg/kg (rats) or 40 mg/kg (mice) of α-thujone and 50 mg/kg (rats) or 80 mg/kg (mice) of α,β-thujone, the bioavailability in rats was generally higher than in mice [NTP 2011, Waidyanatha 2013].

Preclinical safety data

Acute toxicity
The oral LD_{50} of the essential oil in rats was 2.6 g/kg [von Skramlik 1959]. After i.p. administration to rats, cortical phenomena remained subclinical below 0.3 g/kg whereas convulsions appeared above 0.5 g/kg and became lethal above 3.2 g/kg [Millet 1979].

In rats, the oral LD_{50} of thujone (α + β) was 192 mg/kg. I.p. administration led to both convulsant and lethal effects at a dose of 180 mg/kg b.w. [Pinto-Scognamiglio 1967].

The i.p. LD_{50} of α-thujone in mice was 45 mg/kg b.w. [Höld 2000]. It is a reversible modulator of the γ-aminobutyric acid (GABA) type A receptor, but it is rapidly metabolized and detoxified to 7-hydroxy-α-thujone and other metabolites [Höld 2000]. The i.v. LD_{50} for α-thujone in rats was 0.031 mg/kg b.w. [NTP 2011].

The subcutaneous LD_{50} values in mice were determined as 87.5 mg/kg b.w. for α-thujone and 442.4 mg/kg for β-thujone [Rice 1976, Lawrence 1998, Höld 2000].

Subchronic toxicity
In subchronic toxicity tests in rats, oral administration at 10 mg/kg/day produced convulsions in only 1 out of 20 animals by the 38th day [Pinto-Scognamiglio 1967].

Administration of α-thujone and α,β-thujone by gavage to B6C3F1 mice and to Fischer 344 rats at doses of 0, 1, 3, 10, 30 or 100 mg/kg for 14 days produced increased mortality in the group receiving the highest dose associated with neurotoxic effects such as hyperactivity, tremors or tonic seizures [NTP 2011].

Chronic toxicity
α,β-thujone was administered by gavage to B6C3F1 mice at doses of 0, 3, 6, 12, and 25 mg/kg b.w./day and to Fischer 344 rats at doses of 0, 12.5, 25, and 50 mg/kg b.w./day for 2 years. In both species, increased mortality was observed in the group receiving the highest dose and in rats also in the 25 mg/kg group. Clonic and tonic seizures were observed with the middle and the highest dose in rats and with the highest dose in mice. A small increase in clonic seizures was also observed in rats receiving 12.5 mg/kg. The administration of α,β-thujone resulted in increased incidences of non-neoplastic lesions in the brain and spleen of male and female rats, the kidney of male rats and the pituitary gland of female rats, usually at the two highest dose levels. In the rat, the NOAEL value was 12.5 mg/kg for mortality and tonic seizures (no NOAEL for clonic seizures). In the mouse, the NOAEL was 12 mg/kg b.w. for seizures and mortality [NTP 2011].

Mutagenicity
A sage leaf tincture at doses up to 200 µl/plate showed no mutagenic activity in the Ames test using *Salmonella typhimurium* strains TA98 and TA100 with or without S9 metabolic activation [Schimmer 1994]. Sage oil showed no

mutagenic or DNA-damaging potential in the Ames test or *Bacillus subtilis* rec-assay [Zani 1991].

Clinical safety data
In a non-randomized, crossover trial involving six healthy female volunteers, consumption of a tea (4 g/ 300 mL twice a day) for four weeks did not cause any hepatotoxicity or other adverse effects [Sà 2009].

In an open, multicentre trial involving 69 menopausal women given 280 mg thujone-free spissum extract (equivalent to 3.4 g tincture of fresh leaves, DER 1:17, thujone < 10 ppm) for 8 weeks, only mild adverse effects (mild abdominal pain and mild diarrhoea in one patient) were reported. Tolerability was rated as very good by 90% of physicians and patients. A high degree of safety was observed regarding haematological parameters including leukocyte, erythrocyte and thrombocyte counts, as well as creatinine and bilirubin levels [Bommer 2011].

In a randomized, triple-blind, placebo-controlled trial involving 86 women and men with type 2 diabetes taking 500 mg of an extract (4:1; ethanol 80%) every 8h for 3 months, no significant ($p>0.05$) effects on hepatic and renal function parameters compared to the placebo group were reported [Kianbakht 2013].

In a randomized, triple-blind clinical trial, 90 volunteers received either 500 mg of an extract (20:1; ethanol 96%) or placebo daily, from day 21 of their cycle until day 4 of the next cycle, for two consecutive months. A questionnaire to assess side effects included 9 items and revealed increased bleeding and skin allergy in one case in the verum group as well as one case of allergy and gastrointestinal problems in the placebo group [Abdnezhad 2019].

Two cases of intoxication in children due to accidental use of sage oil have been reported: Shortly after accidental topical exposure, a 33-day-old boy showed recurrent generalized tonic-clonic convulsion, nystagmus, hyperreflexia and irritability. After the second day of hospitalisation seizures stopped. No sustained or irreversible neurologic effect were observed. A 5 ½ year-old girl manifested tonic-clonic seizures that lasted 10 minutes shortly after accidental intake of approximately 5 mL of sage oil [Halicioglu 2011, Lachenmeier 2012].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)

SALVIAE TRILOBAE FOLIUM

2014

Sage Leaf, Three-lobed

DEFINITION

Three-lobed sage leaf consists of the whole or cut, dried leaves of *Salvia fruticosa* Mill. [syn. *S. triloba* L.fil.]. It contains not less than 18 ml/kg of essential oil in the whole drug, and not less than 12 ml/kg of essential oil in the cut drug, both calculated with reference to the dried material.

The material complies with the monograph of the European Pharmacopoeia [Sage leaf, three-lobed].

CONSTITUENTS

1.5-3.5% of essential oil consisting mainly of terpenes with cineole (40-67%), α- and β-thujone (2-6%), camphor (1-24%), camphene (0.3-5%), borneol (1%), β-caryophyllene, α- and β-pinene, bornyl acetate, limonene, linalyl acetate and viridoflorol [Länger 1996; Stahl-Biskup 2008; Pitarokili 2003; Brand 2008; Papageorgiou 2008].

Other characteristic constituents include phenolic acids (1-4%) such as 3,4-dihydroxybenzoic, rosmarinic and caffeic acids [Brand 2008; Papageorgiou 2008]; flavonoids such as salvigenin, glucosides and glucuronides of apigenin, chrysoeriol, hispidulin, luteolin, 6-methoxyluteolin and jaceosidin [Abdalla 1983; Brand 2008]; diterpenes such as carnosol and triterpenes such as ursolic and oleanolic acids (< 8%) [Stahl-Biskup 2008; Brand 2008].

CLINICAL PARTICULARS

Therapeutic indications

Inflammations and infections of the mouth and throat such as stomatitis, gingivitis and pharyngitis [Stahl-Biskup 2008; Benedum 2006]; digestive disorders such as dyspepsia [Benedum 2006].

Efficacy for these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Topical use
Adult daily dose: An infusion of 3 g of dried drug in 125 ml of water as a mouthwash or gargle [Stahl-Biskup 2008; Böhme 2010].

Oral use
Adult dose: 1-1.5 g of dried drug as an infusion in 150 ml of water, once or several times daily [Stahl-Biskup 2008; Böhme 2010].

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported [Williamson 2009].

E/S/C/O/P MONOGRAPHS

Pregnancy and lactation
No data available. In accordance with normal medical practice, three-lobed sage leaf should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Data relating to the essential oil and lipophilic extracts are included below for completeness, although their components are present to only a minor extent in aqueous preparations such as those recommended under Dosage.

Pharmacodynamic properties

In vitro experiments

Antioxidant and radical-scavenging activity
An aqueous extract (0.25 g/10 ml, 1.4% polyphenols) showed antioxidant activity of 53.5 µmol trolox equivalents per g of dry plant material and an 80% methanolic extract (0.25 g/10 ml, 2.4% polyphenols) 175 µmol trolox equivalents per g of dry plant material in the 2,2'-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid) diammonium salt (ABTS) radical cation decolourisation test [Tawaha 2007].

In the deoxyribose assay an infusion (1 g/25 ml) exhibited antioxidant activity in the presence or absence of digestive enzymes and bile salts. The amount of total dialysable iron was increased compared to the Fe(III) control under simulated gastric conditions [Matsingou 2000].

An acidic aqueous methanolic dry extract (30% V/V, 3.4-5.2:1) had an IC_{50} value of 0.021-0.046 g/litre in the DPPH assay and was also active in the ABTS cation decolourisation assay. The free radical scavenging activity in both assays was correlated with the total phenolic content (6.4-14.4%) determined by a colorimetric method [Papageorgiou 2008].

An ethanolic dry extract (1.6:1) and an acetone dry extract (4.2:1) reduced DPPH by 98.5% and 97.6% respectively. Antioxidant activity of these extracts was also observed in the phosphatidylcholine liposome assay. The protective effect of the extracts against oxidation of sunflower oil under accelerated conditions (120°C) was evaluated in a Rancimat apparatus using 0.02% (w/w) of extract in bulk oil; the ethanolic and acetone extracts protected the oil by factors of 1.7 and 2.2 compared to a blank control [Exarchou 2002]. In another study using the Rancimat method a methanolic dry extract (3.8:1) protected sunflower oil from oxidation by a factor of 1.08 at 0.02% and 3.03 at 1% [Bozan 2002].

Free radical scavenging activity of the essential oil of three-lobed sage leaf harvested during different seasons, and some of its components, was determined in the DPPH assay. IC_{50} values of the essential oils were between 2.4 and 5.2 g/litre, while that of β-caryophyllene was 18.6 g/litre, and 1,8-cineole and α-pinene were inactive; IC_{50} values of the positive controls, ascorbic acid and butylated hydroxytoluene, were 0.06 g/litre and 0.08 g/litre respectively. A positive correlation was found between free radical scavenging activity and concentrations of oxygenated sesqui- and diterpenes [Papageorgiou 2008].

Acetyl- and butyrylcholinesterase inhibitory activity
A dichloromethane dry extract (13.4:1) inhibited acetylcholinesterase activity by 27% at 25 µg/ml and 51% at 100 µg/ml [Senol 2010].

In another study, a 75%-hydroethanolic dry extract (1 g/60 ml; 1% total phenols) inhibited acetylcholinesterase activity with an IC_{50} of 0.71 mg/ml [Orhan 2009].

An ethyl acetate dry extract (1 g/20 ml) slightly inhibited acetylcholinesterase activity, by 28% at 1.0 mg/ml and 11% at 0.25 mg/ml, while a dry aqueous extract (1 g/20 ml) was inactive [Salah 2005].

In an assessment of the inhibition of human cholinesterases by three-lobed sage leaf essential oil, contradictory results were obtained in the case of butyrylcholinesterase, whereas IC_{50} values of 0.04-0.06 mg/ml were reported for inhibition of acetylcholinesterase. The most pronounced acetylcholinesterase inhibition by individual components of the oil was observed for 1,8-cineole (IC_{50}: 0.06 mg/ml), β-caryophyllene (IC_{50}: 0.03 mg/ml), α-pinene (IC_{50}: 0.1 mg/ml) and β-pinene (IC_{50}: 0.2 mg/ml); α-thujone and camphor at 0.5 mg/ml inhibited the enzyme by 37% and 13% respectively. No or only low butyrylcholinesterase inhibition was observed with all tested compounds [Savelev 2004].

Cytotoxic activity
An aqueous dry extract (2 g/150 ml, 71.5 µg/ml rosmarinic acid, 28.6 µg/ml 6-hydroxyluteolin-7-glucoside, 29.4 µg/ml other phenolic compounds, lyophilised) at 50 µg/ml significantly inhibited cell proliferation in the human colon cancer cell line HCT15 (from 26.2% in the control to 4.7%, $p \leq 0.001$). No significant effect was observed in CO115 cells; rosmarinic acid at 10-100 µg/ml was inactive in both cell lines. The extract and rosmarinic acid induced apoptosis in a concentration-dependent manner. In HCT15 cells the extract increased the proportion of apoptotic cells from 0.4% in the control to 6.6% at 50 µg/ml, rosmarinic acid increased numbers to 2.5% ($p \leq 0.001$). In CO115 cells, the proportion of apoptotic cells increased from 1.8% in the control to 6.8% after treatment with the extract and to 3.6% by rosmarinic acid at the same concentrations. No cleaved caspase-9 and caspase-3 were observed 24 hours after treatment.

Both the extract and rosmarinic acid inhibited the mitogen-activated protein kinase / extracellular signal-regulated kinase (MAPK/ERK) pathway in HCT15 cells by 50% ($p \leq 0.001$) and had no effects in CO115 cells. No inhibition on Akt (a serine/threonine kinase) phosphorylation was observed. Both pathways are commonly altered in colorectal carcinoma, and lead to increased proliferation and inhibition of apoptosis [Xavier 2009].

Three-lobed sage leaf essential oil and its main components exhibited cytotoxic activity against African green monkey kidney (Vero) cells. The essential oil caused complete cell death within 24 hours of exposure at a dilution of 1/500 (V/V) and within 48 hours at 1/1000. At 1/2000 a transient decrease in cell viability was initially observed, but this had been overcome after 48 hours. Among the main components at dilutions of 1/1000 (i.e. 0.10%), thujone was the most cytotoxic causing 95% reduction in viability, and camphor showed moderate activity (40% reduction), whereas 1,8-cineole was less active (5% reduction) [Sivropoulou 1997].

In another evaluation of cytotoxic activity, the IC_{50} values for

an undefined dichloromethane-methanol dry extract were 180 µg/ml in mouse fibrosarcoma cells, 250 µg/ml in a benign human breast carcinoma cell line and 290 µg/ml in a metastatic human breast carcinoma cell line [Kaileh 2007].

Spasmolytic activity
A decoction and an infusion from three-lobed sage leaf, and corresponding fractions obtained by partitioning these between benzene and water, as well as a fluid extract (1:2, 70% ethanol), had varying effects on the tone and phasic contractile activity of isolated segments from guinea pig ileum. The decoction, and the aqueous fraction of the infusion, caused contraction of the smooth muscle preparation without affecting phasic contractions, the aqueous fraction of the decoction decreased the tone and caused relaxation, while the fluid extract potentiated phasic activity but did not affect the tone. The infusion caused contraction of the intestinal segments and intensified phasic contractions. All the extracts inhibited contractions induced by acetylcholine (10^{-7} M), barium chloride (10^{-4} M), histamine (10^{-5} M) and serotonin (10^{-5} M) by 20-90% [Todorov 1984].

Antimicrobial and antiviral activity of the essential oil
The essential oil of three-lobed sage leaf exhibited slight inhibitory activity against growth of *Fusarium moniliforme*, *Rhizoctonia solani*, *Phytophthora capsici* [Müller-Riebau 1997], *Botrytis cinerea*, *Fusarium solani* var. *coeruleum* [Daferera 2003], *Trichophyton rubrum* and *Trichosporon beigelii* [Adam 1998]. In tests of the antifungal activity of the essential oil, 1,8-cineole and camphor against 13 other fungal species (type cultures and isolates), such as *Aspergillus* sp., *Penicillium* sp., *Phomopsis*, *Alternaria*, *Microsporum* and *Epidermophyton* sp., minimium inhibitory concentrations (MIC) and minimum fungicidal concentrations (MFC) respectively were found to be: 5.0-15.0 µl/ml and 5.0-20.0 µl/ml for the essential oil, 4.0-9.0 µl/ml and 5.0-15.0 µl/ml for 1,8-cineole, and 3.0-5.0 µl/ml and 3.0-10.0 µl/ml for camphor [Sokovic 2002].

Three-lobed sage leaf essential oil exhibited low activity against *Erwinia herbicola* (MIC: 2 mg/ml) and was inactive against *Pseudomonas syringae*, whereas leaf surface phenolics extracted with dichloromethane inhibited both bacterial strains. Camphor, with an MIC and MBC (minimum bactericidal concentration) of 2 mg/ml, was more effective than 1,8-cineole (both values ≥ 2 mg/ml) [Karamanoli 2000].

Essential oil of three-lobed sage leaf cultivated in Brazil inhibited the growth of *Escherichia coli*, *Proteus mirabilis*, *Salmonella typhimurium*, *Aeromonas* sp., *Klebsiella oxytoca*, *Citrobacter* sp., *Serratia marcescens*, *Bacillus* sp., *Pseudomonas* sp. and *Staphylococcus* sp. The MICs (0.1 to 10 mg/ml) and MBCs (0.1 to >10 mg/ml) indicated that the essential oil of *Salvia triloba* was generally more effective than that of *S. officinalis* against these bacterial strains. The activity was more pronounced against Gram-negative bacteria [Delamare 2007].

In the disk diffusion assay the essential oil, 1,8-cineole and thujone showed moderate activity against a selection of eight bacteria, *Salmonella typhimurium* being the most resistant and *Pseudomonas aeruginosa* being the most sensitive, while camphor was almost inactive. The essential oil was bactericidal against *Staphylococcus aureus* at 1/4000 dilution, while dilutions up to 1/10000 caused a considerable decrease in bacterial growth rates [Sivropoulou 1997].

Hydrosols of three-lobed sage leaf (the aqueous phases obtained by 1 hour of steam distillation) were inactive against fifteen bacterial strains such as *E. coli* or *S. aureus* [Sagdic 2003].

The virucidal activity of three-lobed sage leaf essential oil and its main components was evaluated against HSV-1, an ubiquitous human pathogen. At a concentration of 0.2% the essential oil inactivated 80% of infectious virus within 30 minutes and thujone at 0.1% inactivated 95%, whereas 1,8-cineole and camphor at 0.1% inactivated 35% and 0% respectively [Sivropoulou 1997].

Other effects
Pretreatment of murine fibrosarcoma cells with a dichloromethane-methanol dry extract at 62.5 µg/ml revealed a weak inhibitory effect on the IL-6 promoter and the recombinant NFκB promoter construct [Kaileh 2007].

An ethanolic extract showed moderate binding affinity at the $GABA_A$-benzodiazepine receptor site [Salah 2005].

In vivo experiments

Antidiabetic activity
The hypoglycaemic activity of a 10% infusion was evaluated in normoglycaemic rabbits and rabbits with alloxan-induced diabetes. A single oral dose of 2.5 ml/kg b.w. (corresponding to 0.25 g/kg of dried leaf) had no acute effect on blood glucose levels in either group. Repeated oral administration at 2.5 ml/kg/day over a period of 7 days produced a significant reduction of blood glucose levels in hyperglycaemic rabbits but had no effect in normoglycaemic animals. Compared to hyperglycaemic control animals, blood glucose levels in treated hyperglycaemic rabbits were 20.2% lower 60 minutes after the last administration of infusion ($p<0.05$), 24.9% lower after 90 minutes ($p<0.01$) and 25.7% lower after 120 minutes ($p<0.01$).

After oral glucose loading at 1 g/kg, administration of a single oral dose of the infusion at 0.25 ml/kg significantly reduced blood glucose levels in both normo- and hyperglycaemic animals, the effect being more evident in the latter. In treated hyperglycaemic rabbits the increase in blood glucose was only 19.2% ($p<0.05$), 7.8% ($p<0.01$) and 7.1% ($p<0.01$) after 60, 90 and 120 minutes, compared to 78.2%, 73.1% and 55.5% in hyperglycaemic control animals receiving water only.

A single oral administration of the infusion had no significant effects on plasma insulin levels in any group of rabbits following oral glucose loading, nor on blood glucose levels in normoglycaemic animals after intravenous glucose loading. The results suggested that three-lobed sage leaf does not influence glucose metabolism; the hypoglycaemic activity might be due to inhibition of intestinal absorption of glucose [Perfumi 1991].

In another study, the effect of an infusion (5:1) in streptozotocin (STZ)-induced diabetic rats was investigated. One week after i.p. injection of a single dose of 45 mg/kg b.w. STZ, the glucose level was 311 ± 25 mg/dL in diabetic rats (n=12) compared to 119 ± 4 mg/dL in healthy rats (n=12). In water drinking STZ-diabetic animals (n=6), plasma glucose levels continued to increase throughout the 14-day experimental period but remained stable in STZ-diabetic animals (n=6) drinking the infusion (0.28% w/v, ad libidum) ($p<0.01$ on day 14). In non-diabetic animals glucose levels were not influenced by drinking the infusion (n=6). The administration of the infusion did not significantly change the liver glycogen content or induce liver toxicity or increase the regeneration of β-cell mass. The increase in intestinal Na^+/glucose cotransporter-1 (SGLT1), localized to the enterocyte brush-border membrane, was significantly abrogated by treatment with the infusion (30% compared to untreated animals, $p<0.01$) without changes in total cellular transporter protein levels. Comparable results were obtained in rats with high carbohydrate diet-induced diabetes (n=6) drinking the infusion (32%, $p<0.05$) when compared to a water drinking group (n=6). Rosmarinic acid (0.58 mg/mL) in the drinking water inhibited SGTL1 to 50% ($p<0.01$). No effects

were observed on glucose transporter 2, Na^+/K^+-ATPase or glucagon-like peptide-1 levels by the treatment [Azevedo 2011].

Antihypertensive activity
A dry decoction, administered intraperitoneally to nembutal-anaesthetized, spontaneously hypertensive rats as a single dose of 50 mg/kg b.w., reduced blood pressure by 31% compared to saline controls after 120 minutes [Todorov 1984].

Anti-inflammatory activity
Three-lobed sage leaf was successively extracted with chloroform (dry yield: 6.75%), ethanol (4%), butanol (1%) and water (> 20%, viscous extract). Oral administration of the chloroform fraction at 25 mg/kg b.w. significantly inhibited carrageenan-induced rat paw oedema by 17% ($p<0.01$) compared to 47% by diclofenac at 10 mg/kg as positive control ($p<0.01$); the other fractions were less effective. In the cotton pellet granuloma assay the chloroform fraction inhibited chronic mean gain in pellet weight by 18 mg compared to 29 mg by diclofenac ($p<0.01$) [El-Sayed 2006].

Central effects
A dry decoction and the dry benzene fraction from an infusion, administered subcutaneously to mice at 100 mg/kg b.w. 10 minutes before administration of hexobarbital (80 mg/kg b.w.), delayed the onset of sleep [Todorov 1984].

In another study, a 75%-hydroethanolic dry extract (1g/60 ml; total phenolic content: 10.9 mg/g, expressed as gallic acid equivalent) exerted dose-dependent anti-amnesic activity in mice. A passive avoidance apparatus (step-through type) was used to investigate long-term memory; amnesia was induced by scopolamine (1 mg/kg, given intraperitoneally 30 minutes after oral administration of the extract) and donezepil was used as a positive control. The extract had a relative memory-enhancing effect of 57.1 and 71.4% at 200 and 400 mg/kg b.w. respectively (control group 0%, donezepil group set to 100%) [Orhan 2009].

Clinical studies
No clinical studies have been published on mono-preparations of three-lobed sage leaf.

Pharmacokinetic properties
No data available.

Preclinical safety data

Mutagenicity
An aqueous dry extract (1 g/100 ml, extracted at 50°C) at 40 and 80 µg per plate showed no mutagenic potential in the Ames test using *Salmonella typhimurium* strains TA98 and TA100 with and without metabolic activation. In the alkaline single cell gel electrophoresis (COMET) assay in human lymphocytes treatment with 40 µg of the aqueous dry extract produced a significant increase in COMET tail moments when compared to the positive control, 4 mM hydrogen peroxide (22.0 vs 13.2, $p<0.01$) [Basaran 1996].

Essential oil of three-lobed sage leaf at concentrations of 250-2000 ppm did not exhibit any mutagenic activity in the Ames test using *S. typhimurium* strains TA97, TA98, TA100 and TA102 in [Adam 1998].

Effects on fertility
Ingestion of an aqueous dry extract by female rats at 200, 400 and 800 mg/kg b.w. from days 1 to day 6 of pregnancy had no significant effects on the number of pregnancies, implantations, viable fetuses or resorptions when compared to the control. Intragastric administration of a 95%-ethanolic dry extract at 400 mg/kg also had no effect on the number of pregnancies or implantations; however, the number of viable fetuses decreased ($p<0.005$) and the number of resorptions increased ($p<0.005$).

In contrast, intragastric administration of the aqueous dry extract at 800 mg/kg or the ethanolic dry extract at 400 mg/kg to adult female rats for 30 consecutive days had no effect on the occurrence of pregnancy, but the number of implantations ($p<0.05$) and viable fetuses ($p<0.01$) decreased and the number of resorptions increased ($p<0.01$ for aqueous dry extract, $p<0.005$ for ethanolic dry extract). Ingestion of the same extracts at the same dosage levels for 30 consecutive days by adult male rats had no effect on the final proportion of pregnant females impregnated by these males; however the number of implantations and viable fetuses were reduced in such females ($p<0.01$ for aqueous dry extract, $p<0.001$ for ethanolic dry extract), whereas the number of resorptions increased ($p<0.005$). Prenatal exposure of male and female rat offspring to the ethanolic dry extract at 400 mg/kg had no effect on the timing of testicular descent or vaginal opening [Al-Hamood 1998].

Ulcerogenicity
Three-lobed sage leaf was successively extracted with chloroform (dry yield: 6.75%), ethanol (4%), butanol (1%) and water (> 20%, viscous extract), and each fraction was orally administered to rats at 25 mg/kg b.w. The ulcer indices were 0 for the ethanol fraction, 1.2 for the water fraction ($p<0.01$) and 1.3 for the chloroform fraction ($p<0.01$), compared to 12.3 for acetylsalicylic acid at 1 mg/kg ($p<0.01$) [El-Sayed 2006].

Toxicity of thujone
Although α-thujone is present in the essential oil of three-lobed sage leaf, the proportion is far less than in essential oils of *Salvia officinalis* or *Artemisia absinthium*; aqueous preparations are unlikely to contain toxic amounts of α-thujone.

Clinical safety data
No data available.

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

SAMBUCI FLOS

2013

Elder Flower

DEFINITION

Elder flower consists of the dried flowers of *Sambucus nigra* L. It contains not less than 0.8% of flavonoids, expressed as isoquercitrin ($C_{21}H_{20}O_{12}$; M_r 464.4) and calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Elder flower].

CONSTITUENTS

The characteristic constituents are flavonoids (0.7-3.5%) such as rutin, isoquercitrin, hyperoside, astragalin and glycosides of isorhamnetin [Dawidowicz 2006, Leifertova 1971, Lin 2007, Males 1999, Petitjean-Freytet 1991]; about 3% of phenolic acids (chlorogenic, ferulic and $_p$-coumaric acids) and their glycosides [Leifertova 1971, Lin 2007, Males1999, Petitjean-Freytet 1991]; and 0.1-0.3% of essential oil consisting mainly of monoterpenes such as linalool and its oxides, citronellol and hotrienol [Eberhardt 1985a, Eberhardt 1985b, Jørgensen 2000, Kaack 2006, Velísek 1981].

Other constituents include fatty acids and alkanes [Richter 1974, Toulemonde 1983], triterpenes such as α- and β-amyrin and ursolic acid, sterols [Makarova 1997, Willuhn 1977], *N*-phenylpropenoyl-L-amino acid amides (0.01%) such as N-(*E*)-caffeoyl-L-aspartic acid amide [Hensel 2007], and about 2% of potassium [Szentmihályi 1998].

CLINICAL PARTICULARS

Therapeutic indications

As a diaphoretic in the treatment of common cold, fever and chills [Bradley 1992, Hiermann 1994, Willuhn 2002].

Efficacy is plausible for this indication on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Adult dose, three times daily: 3-5 g of dried flowers as an infusion; 3-5 ml of liquid extract (1:1, ethanol 25% V/V); 10-25 ml of tincture (1:5, ethanol 25% V/V) [Bradley 1992, Hiermann 1994, Willuhn 2002].

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with normal medical practice, elder flower should not be used during pregnancy and lactation without medical advice.

E/S/C/O/P MONOGRAPHS

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antioxidant and radical scavenging activity
Free radical scavenging and antioxidant activities of hydroethanolic (80% V/V) extracts of elder flower obtained by pressurized liquid extraction at varying temperatures (20-200°C) were determined in the DPPH assay. The extract obtained at 20°C (1.4% flavonoids) reduced DPPH by 92% after 120 minutes, and the extract obtained at 100°C (2.1% flavonoids) by 94% [Dawidowicz 2006].

Antiadhesive activity
Preincubation of *Helicobacter pylori* with N-(*E*)-caffeoyl-L-aspartic acid amide (1 mg/ml) led to strong and reproducible inhibition of adhesion of the bacteria to sections of human stomach mucosa. No bactericidal or bacteriostatic activities were observed [Hensel 2007].

Anti-inflammatory activity
A dry aqueous extract of elder flower (0.25 mg/ml) inhibited PAF-induced exocytosis of elastase from human neutrophils by 57% in a spectrophotometric assay compared to distilled water as a blank. The positive control (ginkgolide B) inhibited exocytosis by 60% [Tunon 1995].

A dry methanolic extract of elder flower (30 µg/ml in DMSO) inhibited release of the cytokines IL-1α, IL-1β and TNF-α from human peripheral mononuclear cells by 44, 49 and 50% respectively, compared to a solvent blank. A dry hexane fraction (38, 45 and 31% inhibition respectively) and a dry chloroform fraction (31, 44 and 57% inhibition respectively) from the methanolic extract showed comparable activity, whereas a dry *n*-butanol fraction and the residual water showed lower or no activity at this concentration [Yesilada 1997].

An infusion of elder flower (≥0.005 g/100 ml) significantly inhibited induction of TNF-α release ($p<0.05$) from LPS- and fimbriae-stimulated human monocytic THP-1 cells (cells differentiated into macrophages). Complete inhibition was achieved at 0.16 g/100 ml. Release of the pro-inflammatory cytokines TNF-α, IL-1β and IL-6 using additional bacterial stimuli was also potently inhibited in the monocytic THP-1 cells, as well as in mouse macrophages, at the same concentrations. In contrast, release of the anti-inflammatory cytokine IL-10 was only moderately inhibited. The infusion significantly inhibited activation of NF-κB, a central factor in pro-inflammatory gene expression, by several stimuli ($p<0.05$) at 0.08 g/100 ml in both human and mouse macrophages. Bacterial activation (by *Porphyromonas gingivalis*) of integrin, a possible effector of pathological inflammation, in human neutrophils was significantly suppressed by the same infusion ($p<0.05$ at 0.08-0.3 g/100 ml). The greatest inhibition of 73-76%, observed at a dilution of 0.3 g/100 ml, was at least as effective as a positive control. The oxidative burst of PMA- and bacteria-activated human neutrophils, monitored by a dichlorofluorescein assay, were significantly and concentration-dependently inhibited by the same elder flower infusion ($p<0.05$). Almost complete inhibition was observed at 0.16 and 0.3 g/100 ml respectively [Harokopakis 2006].

N-(*E*)-caffeoyl-L-aspartic acid amide (10 µg/ml) significantly increased mitochondrial dehydrogenase activity ($p<0.05$) in HepG2 human liver cells by 52%, estimated by the MTT assay after 48 hours. In human keratinocytes, mitochondrial activity and the mitotic cell proliferation rate both increased by about 55% after 60 hours of incubation ($p<0.01$) at 10 µg/ml. In HepG2 cells proliferation was slightly enhanced. No necrotic cell toxicity was observed [Hensel 2007].

Antidiabetic activity
An aqueous extract of elder flower (1 g/litre) increased glucose uptake by 70% ($p<0.05$), glucose oxidation by 50% ($p<0.01$) and glycogenesis by 70% ($p<0.05$) in the absence of insulin in an isolated insulin-sensitive mouse abdominal muscle preparation, but did not significantly alter the insulin stimulus. The extract (0.25-1 g/litre) exerted a significant stimulatory effect on insulin secretion from clonal pancreatic β-cells in a concentration-dependent manner (4.5 pmol insulin/million cells after 20 minutes at 1 g/litre, $p<0.01$). This insulin-releasing effect was significantly potentiated in the presence of 16.7 mM glucose ($p<0.001$). The activity decreased by 41% after the removal of constituents of MW < 2000 Da. Consecutive extraction of elder flower with *n*-hexane, ethyl acetate, methanol and water showed that only the methanol and water extracts increased insulin release ($p<0.001$). Known elder flower constituents such as rutin, lupeol and β-sitosterol had no effect on insulin release [Gray 2000].

In vivo experiments

Diuretic activity
A dry aqueous elder flower extract (approximately 5:1), administered intraperitoneally in saline to rats as a single dose of 50 mg/kg b.w., significantly increased urinary volumes compared to a saline control in the period from 2 to 24 hours after administration (after 2 hours, 2.4 ml urine/100 g vs. 1.6 ml urine/100 g, $p<0.05$; after 24 hours, 7.5 ml urine/100 g vs. 5.8 ml urine/100 g, $p<0.01$). Urinary volumes obtained with hydrochlorothiazide (10 mg/kg) were 2.8 ml/100 g after 2 hours and 7.1 ml/100 g after 24 hours ($p<0.05$). Increases in urinary excretion of sodium and potassium were observed after 8 hours, while the pH remained unchanged (pH 8.4-8.8). The saline overload was eliminated within 5.0 hours in the case of the elder flower extract and within 5.3 hours in the case of hydrochlorothiazide [Beaux 1999].

Anti-inflammatory activity
Intragastric administration of an elder flower dry extract (ethanol 80% V/V) at 100 mg/kg b.w. inhibited carrageenan-induced rat paw oedema by 27% ($p<0.01$) compared to 45% by indomethacin at 5 mg/kg [Mascolo 1987].

In another study, intraperitoneal administration of an unsaponifiable fraction of elder flower to mice at 0.5 ml/animal moderately enhanced phagocytosis [Delaveau 1980].

Secretolytic activity
Daily intragastric administration of a hydroethanolic extract (19% V/V, corresponding to 0.6 g elder flower/100 ml) to rabbits at 6.5 ml/kg b.w. for 3 days significantly increased bronchial secretion by 43% compared to the control (19% V/V ethanol) and by 111% compared to physiological saline ($p<0.01$) [Chibanguza 1984].

Pharmacokinetic properties
No data available.

Preclinical safety data

Acute toxicity
After daily intragastric administration of a hydroethanolic extract (19% V/V, corresponding to 0.6 g elder flower/100 ml) to rabbits at 6.5 ml/kg b.w. for 3 days, no significant changes in breathing and pulse rates, number of erythrocytes or sodium, calcium and potassium concentrations were observed, compared to the control (19% V/V ethanol) [Chibanguza 1984].

Clinical safety data
No data available.

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

Front cover
Title page
Verso
Foreword and Preface
Notes for the Reader
Abbreviations
The monograph text
Back cover

Information on the member organizations and people involved in ESCOP's activities can be found on the website (www.escop.com):

Members of ESCOP

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

SERPYLLI HERBA

2014

Wild Thyme

DEFINITION

Serpylli herba consists of the whole or cut, dried, flowering aerial parts of *Thymus serpyllum* L.s.l. It contains not less than 3.0 mL/kg of essential oil (dried drug).

The material complies with the European Pharmacopoeia [Wild thyme].

CONSTITUENTS

Essential oil: 0.1 to 0.6% with carvacrol as major compound and variable amounts of thymol, linalool, linalyl acetate, borneol, 1,8-cineole, germacrene D, p-cymene, γ-terpinene, myrcene, β-caryophyllene [Loziene 1998; Mockute 2004; Raal 2004; Sefidkon 2004; Stahl-Biskup 2007; Paaver 2008; Cavar 2009, Schilcher 2010, Nedorostova 2011, Hussain 2013]. The composition depends largely on the species, genotype, ontogenic development, origin and growth conditions [Rasooli 2002].

Triterpenoids such as ursolic acid (0.9 to 1.4%) and oleanolic acid (0.37 to 0.48%), and low amounts of 3β-hydroxyolean-12-en-28-oic acid and dihydroursolic acid [Janicsak 2006; Aziz 2008; Stahl-Biskup 2009].

Hydroxycinnamic acids (1.3 to 6.8%) with rosmarinic acid (0.76 to 2.44%) and lithospermic acid (0.31 to 4.28%) as main components [Ziakova 2003; Kulisic 2007; Stahl-Biskup 2007; Fecka 2008, Boros 2010].

Flavonoids (0.95 to 2.99%) such as luteolin-7-O-glucuronide, luteolin-7-O-glucoside, luteolin-7-O-rutinoside, eriocitrin or scutellarin-7-O-β-D-glucopyranosyl(1→4)-O-α-L-rhamnopyranoside [Washington 1986; Kulisic 2007; Fecka 2008, Miron 2011].

Tannins (3.4 to 7.4 %) [Stahl-Biskup 2009, Komes 2011]; amino acids [Mazulin 2002].

CLINICAL PARTICULARS

Therapeutic indications

Internal use:
Catarrh of the upper respiratory tract [Jänicke 2003; Schilcher 2010; Stahl-Biskup 2007; Stahl-Biskup 2009].

External use:
As a bath additive in the supportive treatment of acute or chronic diseases of the respiratory tract [Jänicke 2003; Stahl-Biskup 2007].

Efficacy in these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Internal use:
Adult daily dose: 4-6 g of the drug [Jänicke 2003; Schilcher 2010; Stahl-Biskup 2007; Stahl-Biskup 2009].
As an infusion, 2 g (1 - 2 teaspoons) in 150 mL of water, 1 cup before meals 2 to 3 times daily [Jänicke 2003; Stahl-Biskup 2007; Stahl-Biskup 2009].

External use:
Decoction: 1 g of the drug per litre of water [Jänicke 2003].

Method of administration
For oral administration and local application.

E/S/C/O/P MONOGRAPHS

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antioxidant activity
An extract (80% methanol; 5:1) exhibited antioxidant activity in the ferrylmyoglobin/$ABTS^{\bullet+}$ assay with a Trolox equivalent antioxidant capacity of 14.7 mM/g dry weight. The effect correlated with the content of total phenolics [Alzoreky 2001].

A ferric reducing/antioxidant power (FRAP) of 10.9 mmol/L was determined for an infusion (3 g/200 mL); this correlated with the total phenol content; a phenol antioxidant coefficient (FRAP/ total phenolics) of 3.7 was found [Katalinic 2006].

In a broad screening for antioxidant activity, an infusion (15 g/150 mL dried and residue redissolved to 60 g/L) had an IC_{50} of 0.45 g/L in the diphenylpicrylhydrazyl (DPPH) assay and an antioxidant activity index of 1.90 in the Rancimat assay. The activity in the carotene bleaching assay was low and the infusion remained without effect in the TBARS assay [Kulisic 2006].

An infusion (2 g/200 mL) showed antioxidant activity in the ABTS assay (equivalent to 2.44 mM Trolox after 5 min extraction). After 15 min extraction the activity was equivalent to approximately 3.6 mM Trolox and after hydrolysis of the extract to approximately 4.8 mM Trolox. In the FRAP assay the capacity was equivalent to 7.48 mM Fe(II) after 5 min extraction, 6.49 mM Fe(II) after 15 min extraction and approximately 16 mM Fe(II) after hydrolysis [Komes 2011].

In the carotene/linoleic acid assay extracts from wild thyme inhibited lipid peroxidation with IC_{50} values of 261 µg/mL (water extract), 41.2 µg/mL (ethanolic extract) and 96.9 µg/mL (essential oil), whereas the IC_{50} of butylated hydroxytoluene (BHT) as positive control was 12 µg/mL. The IC_{50} values in the DPPH assay were 31.6 µg/mL for the water extract, 13.2 µg/mL for the ethanolic extract and 15.7 µg/mL for BHT [Mata 2007].

Copper-induced LDL oxidation was inhibited by an infusion as well as by the essential oil of wild thyme at concentrations of 0.02 g/L [Kulisic2007].

The relative inhibition of copper-catalyzed oxidation of human LDL by the essential oil was 45.5% [Teissedre 2000].

In the DPPH assay the essential oil showed a radical scavenging activity equivalent to 87% of the activity of BHT [Topal 2008].

Antimicrobial activity

In a disc diffusion assay the essential oil showed strong bactericidal activity against *Staphylococcus aureus* and *Bacillus subtilis* [Rasooli 2002].

S. aureus, Yersinia enterocolitica and two strains of *E. coli* were inhibited by the essential oil as shown in a disc diffusion assay and by serial dilution method [Sagdic 2003].

Wild thyme essential oil was in the group with the highest inhibitory activity against infectious vaginal microorganisms such as *Candida albicans, Streptococcus agalactiae* and *Enterococcus faecalis* [Arnal-Schnebelen 2004].

In an agar dilution test the essential oil was found to have MICs of <0.05 to <0.2% and maximal tolerated concentrations of <0.006 to <0.05% (v/v) against *E. coli*, *Salmonella typhimurium*, *S. aureus* and *Listeria monocytogenes* [Oussalah 2007].

The antibacterial activity of the essential oil against different strains of *S. aureus* was also tested in the vapour phase. MICs for two methicillin-sensitive strains were 33 µL/L, for MRSA 260 µL/L and for several clinical isolates of *S. aureus* between 66 and 130 µL/L [Nedorostova 2012].

In another study using the agar diffusion method, the essential oil of wild thyme was the most active against *E. coli, S. aureus, Klebsiella pneumoniae* and *Staphylococcus epidermidis* as compared to 18 other essential oils [Bulut 2009].

Spore germination and mycelial growth of different *Aspergillus* species were inhibited by the essential oil in a dose-dependent manner. The inhibition of sporulation was less pronounced [Rahman 2003].

In a box vapour assay for antifungal activity the essential oil was tested and showed high potency against *Trichophyton mentagrophytes*. The activity was attributed to the content of carvacrol. The results correlated with those of an agar diffusion assay [Inouye 2006].

Acetylcholinesterase inhibitory activity
The essential oil of wild thyme showed the strongest inhibition of acetylcholinesterase (IC_{50} 190 µg/mL) as compared to an ethanolic (IC_{50} 252 µg/mL) and an aqueous extract (IC_{50} 348 µg/mL) of the same plant material [Mata 2007].

Antiproliferative effects
A methanolic dry extract (not further specified) showed cytotoxic activity against MCF-7 and MDA-MB-231 breast cancer cells with IC_{50} values of 509 and 276 µg/mL. The extract induced apoptosis as shown via analysis of DNA fragmentation and caspase 3/7 activity. The activities of DNA methyltransferase and histonedeacetylase were significantly reduced by 250 and 500 µg/mL of the extract ($p<0.05$) [Bozkurt 2012].

The essential oil exhibited an antiproliferative activity in MCF-7 cells (IC_{50} 95.8 µg/mL), LN-CaP prostate cancer cells (IC_{50}

105.0 µg/mL) and NIH-3T3 fibroblasts (IC_{50} 105.0 µg/mL) [Hussain 2013].

In vivo experiments
Administration of a freeze dried aqueous extract of wild thyme to euthyroid rats (2.5 mg/100 g b.w. i.v.) decreased serum thyroid stimulating hormone (TSH) concentration by about 50% within 3 hours compared to the control group. The pituitary TSH concentration was significantly reduced to approximately 40% of control ($p<0.005$-0.001). The concentrations of thyroxine (T4) remained unchanged while triiodothyronine (T3) was slightly decreased. After a high dose of 40 mg/100 g b.w. the serum TSH level and thyroidal secretions decreased rapidly and remained suppressed during the 12 hours observation period. There was also a significant reduction ($p<0.005$-0.001) in the T4 and T3 levels at 3 and 6 hours post-injection. Serum prolactin levels were significantly increased after the low dose (2.5mg/100g; $p<0.05$); but significantly decreased after the high dose (40mg/100g; $p<0.005$-0.001), this effect vanished between 6 and 12 hours after injection. In goitrous rats, a 70% ethanolic extract (5 mg/kg b.w. i.v.) led to a significant decrease ($p<0.05$-0.01) in the serum TSH concentration. However, the pituitary TSH concentration was increased significantly ($p<0.05$) only by an ethanolic extract oxidized with KMnO4 [Sourgens 1982].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

SOLIDAGINIS VIRGAUREAE HERBA 2018

European Goldenrod

DEFINITION

European Goldenrod consists of the whole or fragmented, dried, flowering aerial parts of *Solidago virgaurea* L. It contains minimum 0.5 per cent and maximum 1.5 per cent of flavonoids, expressed as hyperoside ($C_{21}H_{20}O_{12}$; M_r 464.4) (dried drug).

The material complies with the monograph of the European Pharmacopoeia [Goldenrod, European].

CONSTITUENTS

Flavonoids (approx. 1.5%) including astragalin, hyperoside, isoquercitrin, nicotiflorin, quercitrin and rutin; triterpene saponins of the oleanane type (0.2 – 0.3%) mainly bisdesmosidic glycosides of polygalacic acid; phenol diglucosides (0.2-1%) leiocarposide and virgaureoside A; caffeic acid derivatives, predominantly 3,5-di-*O*-caffeoylquinic acid (2.8%) and chlorogenic acid (1.1%); phenolic acids such as salicylic and caffeic acid; essential oil (0.4 – 0.6%) [Hiller 1975, 1979, 1985, 1986; 1991; Bader 1990a, 1991, 1992, 1995, 1999; Bradley 2006; Fötsch 1988, Inose 1991, 1992; Kalemba 1992, Miyase 1994; Poetsch 1997; Wittig 1999; Starks 2010].

CLINICAL PARTICULARS

Therapeutic indications
Irrigation of the urinary tract, especially in cases of inflammation and renal gravel, and as an adjuvant in the treatment of bacterial infections of the urinary tract [Schilcher 1990, 1992, 2001; Schmitt 1996; Laszig 1999a, 1999b; Weiß 1999, Bader 2008].

Posology and method of administration

Dosage

Adults: An infusion of 3-5 g of comminuted herbal substance in 150 ml of water, 2-4 times daily. Dry extract: 350-450 mg, 3 times daily [Weiß 1999; Schilcher 2000; Edwards 2015; Volk 2015].

Children: 1-4 years of age, 1-2 g of dried herb daily as an infusion; 4-10 years of age, 2-5 g; 10-16 years of age: 4-8 g [Dorsch 1998].

Method of administration
For oral administration.

Duration of administration
No restriction.

Contra-indications
Known hypersensitivity to plants of the Asteraceae (Compositae) [Lundh 2006; Mills 2005; Schätzle 1998; Zeller 1985].

Special warnings and special precautions for use
European golden rod should not be used in patients with oedema due to impaired heart or kidney function [Mills 2005].

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

E/S/C/O/P
MONOGRAPHS

Effects on ability to drive and use machines
None known.

Undesirable effects
Rare cases of minor gastrointestinal complaints [Mills 2005].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties
European goldenrod has shown diuretic, anti-inflammatory, antimicrobial, antispasmodic and analgesic properties.

In vitro experiments

Spasmolytic activity
A 60% hydroethanolic extract inhibited acetylcholine-induced spasms in isolated guinea pig ileum with 15% of the activity of papaverine [Westendorf 1981]. The extract also inhibited acetylcholine-induced spasms in isolated rat bladder [Westendorf 1983].

An aqueous leaf extract (not further specified) inhibited muscarinic M2 and M3 receptor-mediated contraction of rat and human urinary bladder muscle strips. Radioligand binding and inositol phosphate accumulation showed that the extract at a concentration of 0.01% inhibited muscle contraction through a non-competitive muscarinic receptor antagonism, whereas at a concentration of 0.1% a non-specific inhibitory effect was observed [Borchert 2004].

Diuretic activity
Acylated triterpenoid saponins (especially virgaureasaponin B) transiently changed the cell membrane permeability and induced alterations in ionic homeostasis with enhanced permeability between the intracellular and extracellular compartments [Melzig 2001].

Quercetin and its derivatives inhibited neutral endopeptidase, which regulates the formation of urine via the excretion of sodium ions [Apati 2003].

A flavonoid fraction from a methanolic extract increased urinary calcium excretion [Chodera 1991].

Anti-inflammatory activity
A hydroethanolic extract (containing 0.52 mg/mL of rutin, 0.64 mg/mL of flavonoids and 45.6%V/V of ethanol) at concentrations from 0.01 to 5% inhibited biochemical model reactions (including xanthine oxidase, diaphorase in the presence of the auto-oxidizable quinone juglone, lipoxygenase, dihydrofolate reductase) and photodynamic reactions driven by riboflavin or rose bengal, representing inflammatory situations [Meyer 1990, 1995; Strehl 1995].

A tincture (70% v/v ethanol) and an infusion (1/40) showed *in vitro* radical scavenging activity at 1 mg/mL; as well as inhibition of hydrogen-donating ability and elevated reducing power [Apáti 2003]. A hydromethanolic (50% v/v) extract dose-dependently increased glutathione-S-transferase (GST) activity. Isolated rutin and quercitrin (250 mM) increased dose-dependent GST activity, by 50% and 24.5% respectively, while the aglycone quercetin inhibited the enzyme by 30% at 250 mM. Fractions containing flavonoids showed activating effects while those containing caffeic acid derivatives were inhibitory [Apáti 2006]. The compounds 2'-methoxybenzyl-2-methoxy-6-hydroxy-benzoate and 2'-methoxy-benzyl-2,6-dimethoxybenzoate isolated from a 90% ethanolic extract inhibited the release of TNF-α and IL-6 release from LPS-induced RAW264.7 murine monocytes [Li 2014].

Antibacterial activity
A methanolic extract was active against *Staphylococcus aureus*, *Enterobacter faecalis*, *Escherichia coli* and *Bacillus cereus*. The MIC value against bacteria was 50 µg/mL) [Demir 2009].

Nine clerodane diterpenes, solidagoic acids C-I, cleroda-3,13(14)-dien-16,15:18,19-diolide and cleroda-3,13(14)-dien-15,16:18,19-diolide displayed moderate antibacterial activity against *Staphylococcus aureus* with a MIC from 20 to 60 µg/mL [Starks 2010].

Antifungal activity
Deacylated triterpenoid saponins (virgaureasaponins 1, 2 and 3), showed higher activity against several Candida species (*C. albicans*, *C. tropicalis*, *C. krusei*, *C. parapsilosis*, *C. pseudotropicalis*, *C. guilliermondi*, *C. glabrata*) and *Cryptococcus neoformans* than a mixture of genuine ester saponins [Bader 1990b].

A 75% ethanolic extract (1:1) showed antimycotic activity against dermatophytes, especially against *Trichophyton mentagrophytes*, *Microsporum gypseum* and *Microsporum canis* [Pepeljnjak 1998].

An aqueous extract containing 0.7 mg/mL saponins did not inhibit the growth of *Candida albicans* but did decrease the yeast-hyphal transition, biofilm formation and pre-formed biofilms which are key virulence factors of *Candida albicans* [Chevalier 2012].

A hydromethanolic (50%) extract revealed activity against *Candida albicans* hyphae, the pathogenic form of this yeast. In an activity-guided fractionation from an active saponin fraction six oleanane-type triterpenoid saponins were isolated, of which four showed significant ($p<0.05$) inhibition of *C. albicans* yeast-hyphal conversion [Laurençon 2013].

Immunobiological activity
Mitogenic effects on murine spleen and thymus cells as well as on human mononuclear cells were demonstrated for triterpenoid saponins from European goldenrod. The activity of murine bone marrow macrophages was stimulated and induction of cytotoxic macrophages and TNF-α release from murine macrophages were observed [Plohmann 1997].

Treatment of mouse peritoneal macrophages with isolated 2-methoxybenzyl-2-hydroxybenzoate and benzyl-2-hydroxy-6-methoxybenzoate at concentrations from 1 to 100 µg/mL resulted in a stimulation of macrophage function and TNF-α production [Choi 2005].

Cytotoxic activity
Aqueous and ethanolic extracts exhibited cytotoxic activity on various tumour cell lines, including human prostate (PC3), breast (MDA435), melanoma (C8161) and small cell lung carcinoma (H520) [Gross 2002].

Isolated terpenoids and phenolics showed cytotoxicity against human tumour cell lines (A549-non small cell lung adenocarcinoma, SK-OV-3-ovarian, SK-MEL-2 - skin melanoma, XF498 - CNS and HCT15 - colon). The ED_{50} values ranged from 1.52 to 18.57 µg/mL [Choi 2004].

Erythrodiol-3-acetate, α-tocopherol-quinone and trans-phytol,

isolated from the n-hexane fraction demonstrated cytotoxicity against 5 human cell lines (A-549-lung carcinoma, XF498-CNS carcinoma, SK-MEL-2-melanoma, SH-VO-3-ovarian adenocarcinoma and HCT15 colon adenocarcinoma) [Sung 1999].

In vivo experiments

Diuretic activity
Significant increases ($p<0.01$) in diuresis and excretion of sodium, potassium and chloride were demonstrated in rats after oral administration of an aqueous infusion of European goldenrod containing 0.3% of flavonoids at 4.64 and 10.0 mL/kg b.w.. The increases in urinary sodium, potassium and chloride were considered to be due to the electrolyte content of the administered extracts. The increase in urine volume was more pronounced at the lower dose level [Schilcher 1988].

Isolated leiocarposide had a diuretic effect (20% weaker than that of furosemide at 6 mg/kg) after oral or intraperitoneal administration to rats at 25 mg/kg b.w., but did not influence urinary mineral excretion [Chodera 1985, 1986, 1988; Budzianowski 1999]. Furthermore, leiocarposide had an inhibitory effect on the growth of human urinary calculi implanted into the rat bladder. The growth of renal calculi was significantly decreased after 6 weeks of leiocarposide (25 mg/kg p.o.) administration [Chodera 1988].

A flavonoid fraction from European goldenrod administered to rats resulted in an increase of diuresis (88% after 24h), a decrease of overnight excretion of urine potassium and sodium and an increase of excretion of calcium [Chodera 1991].

Several fractions from a methanol/water extract (70:30) showed significant diuretic and saluretic activity in Sprague Dawley rats. The hydroxycinnamic acid fraction (100 mg/kg p.o.) significantly increased sodium and potassium excretion in urine comparably to furosemide at 10 mg/kg. There was no influence on calcium ion excretion in either the hydroxycinnamic acid or furosemide groups. The flavonoid fraction (100 mg/kg p.o.) did not elevate urine volume or ion excretion. The saponin fraction (25 mg/kg – 100 mg/kg p.o.) increased urine volume and saluretic activity for sodium and potassium ions, comparable to furosemide at 10 mg/kg [Kaspers 1998].

Anti-inflammatory and analgesic activity
Anti-inflammatory and analgesic effects of a hydroalcoholic extract have been demonstrated in various models of inflammation. The activity of the extract was similar to that of salicyl alcohol and indomethacin [Okpanyi 1989].

In Freund's adjuvant-induced arthritis of rat paw, a 46%-ethanolic extract, administered orally at 5 mL/kg on days 15-21 after injection of the adjuvant, significantly ($p<0.05$) reduced the intensity of inflammation to nearly 40% of the control value on day 21 [El-Ghazaly 1992].

A terpene fraction and its components exhibited antiulcer activity in HCl/ethanol induced gastric lesions in Swiss albino mice. At 100 mg/kg p.o., solidagenone demonstrated a significant gastroprotective effect ($p<0.05$) comparable to lansoprazole at 20 mg/kg. Solidagen-6β-ol and 3α-hydroxysolidagenone showed higher activity than solidagenone, while its epimers were inactive [Schmeda-Hirschmann 2002].

Leiocarposide showed anti-inflammatory and analgesic effects after subcutaneous administration to rodents. It inhibited carrageenan-induced rat paw oedema by 20% at 100 mg/kg and 27% at 200 mg/kg ($p<0.05$) after 5 hours, compared to 54% by phenylbutazone at 50 mg/kg. The analgesic effect of leiocarposide at 200 mg/kg in the hot plate test in mice was similar to that of aminophenazone at 50 mg/kg after 0.5 and 1 hour, but considerably weaker after 2 hours [Metzner 1984]. A mixture of saponins from European goldenrod, administered i.v. at 1.25-2.5 mg/kg b.w., had an inhibitory effect on sodium nucleinate-induced rat paw oedema [Jacker 1982].

Antitumour activity
A fraction of an aqueous extract was administered i.p. or s.c. every third day for 25 days in an experimental prostatic tumour model in mice. The growth of the tumours was inhibited at 5 mg/kg b.w. without any apparent side effects [Gross 2002].

Virgaureasaponin E (1 mg/kg/day) showed antitumour activity in the allogeneic sarcoma 180 tumour model and in the syngeneic DBA/2-MC.SC-1 fibrosarcoma tumour model. In mice treated with virgaureasaponin E, phagocytosis of bone marrow cells and proliferation of spleen and bone marrow cells were stimulated in an ex vivo assay; the TNF-α concentration in blood increased considerably compared to the control group [Bader 1996, 1998; Plohmann 1997, 1999].

Other effects
Hypotensive and sedative effects of extracts have been demonstrated in rats (180 and 360 mg/kg of a 2% aqueous extract administered i.v.) [Lasserre 1983] and in dogs (150 mg/kg of a non-specified extract of the leaves) [Ràcz-Kotilla 1977].

A significant increase in ACE activity and serum lactate dehydrogenase, creatine phospokinase, ALT, AST, TC, triglycerides, free fatty acids, cardiac MDA and NO levels, and a significant decrease in levels of GSH and SOD in cardiac tissue ($p < 0.05$) was provoked by s.c. injection of isoproterenol (30 mg/kg; twice at an interval of 24 h, for two consecutive days) in albino rats, when compared to a normal control group. Pretreatment with a methanolic extract (not further specified) for 5 weeks at a dose of 250 mg/kg significantly ($p<0.05$) prevented these observed changes [El-Tantawy 2014].

Pharmacological studies in humans
In a double-blind, crossover study with 22 healthy volunteers, a single oral dose of 5 mL of a tincture (65% ethanol) made from fresh plants (0.57 g per g of tincture) produced a 30% rise in the amount of urine compared to placebo [Brühwiler 1992].

Clinical studies
In an open study in 53 patients suffering from urinary tract inflammation, symptoms disappeared in 70-73% of cases after treatment with a daily dose of 5 mL of a tincture (65% ethanol) made from fresh plants [Brühwiler 1992].

In an open, post-marketing study, 745 patients with irritable bladder were treated daily with 3 x 380 mg of a dry extract (5.4:1). After 2 weeks of treatment, micturition frequency had decreased, and symptom-related responder rates were between 69 and 85% [Schmitt 1996].

The efficacy of a dry extract (5.0-7.1:1, ethanol 30% m/m; 3 × 425 mg of extract daily for 4 weeks on average) was investigated in an open, multi-centre, post-marketing study involving a total of 1487 patients, with subgroups for urinary tract infections, irritable bladder and urinary calculi/renal gravel. For patients with recurrent urinary tract infections (n = 555) the extract alone was as effective as when combined with initial antibiotic treatment [Laszig 1999a, b]. In patients suffering from chronic or recurrent irritable bladder symptoms (n = 512), even incontinence could be improved or eliminated in 2 out of 3 cases. The subgroup with "urinary calculi/renal gravel" comprised 427 patients

(32% of whom had additional urinary tract infections and 11% had additional symptoms of irritable bladder); for the typical symptoms, responder rates of 81% (feeling of pressure in the region of the bladder) to 98% (colics) were determined. Global improvement (CGI-scale) under treatment was evaluated by the physicians as "very much or much better" in 79% of the cases [Laszig 1999b].

In a subgroup analysis of the above study, a subgroup of 512 patients with chronic recurrent irritable bladder condition (aged 13 - 96 years, 77% female) was treated for five weeks with 425 mg of a dry extract (5.0-7.1:1) 3 times per day. 96% of the patients showed improvement recorded by the CGI scale, and in 80% of patients' estimations, effectiveness was good or very good [Pfannkuch 2002].

Case reports on 10 patients treated with the above extract during extracorporeal shock wave lithotripsy in hospital and during 4-week after-care indicated a positive spasmolytic effect from treatment with the extract: no colics occurred and additional spasmolytic drugs were unnecessary [Laszig 1999b].

Pharmacokinetic properties

A 60% ethanolic extract (100 µg/mL) did not influence the expression of CYP1A2 and the transporter protein MDR1 expression in LS180 cells. However, it did induce a 1.9-fold expression of CYP3A4 gene [Brandin 2007].

After oral administration of leiocarposide and salicin to rats, the glycosides were mostly excreted unchanged in urine. Hydrolysis of the ester and glycosidic bonds from leiocarposide to leiocarpic acid and saligenin as well as from salicin to saligenin mainly occurred in the caecum and colon. Saligenin was oxidized to salicylic acid in liver, kidney and lung homogenates. Gentisic acid, product of further oxidation of salicylic acid, was detected only in liver homogenate [Fötsch 1989a].

Experiments in rats demonstrated that leiocarposide is poorly absorbed after oral administration and is mostly excreted unchanged in the faeces, with less than 10% of metabolites found in urine. Of the administered dose, 2% was leiocarpic acid, 3-conjugates (2%), salicylic acid (0.5%), 5-conjugates (0.1%) and salicyluric acid (0.5%). Salicin was well-absorbed and excreted in the urine as unchanged drug (15%) and the following metabolites: 0.1% saligenin, 30% salicylic acid, 5% 5-conjugates, 0.1% salicyluric acid, 2% gentisic acid and 0.1% 2,3-dihydroxy-benzoic acid. The different metabolic rates were explained by the high stability of the ester bond of leiocarposide, which is hydrolyzed in artificial intestinal fluid only very slowly with a $t_{1/2}$ of 41.7 h [Fötsch 1989b].

Preclinical safety data

The oral LD_{50} of leiocarposide in rats was determined as 1.55 g/kg b.w. [Chodera 1985].

The mutagenic potential of NaN3 in AMES assay with *Salmonella typhimurium* TA1535 was inhibited by a n-hexane extract at 2.5 mg/mL, whereas ethanolic extracts (> 5 mg/mL) did not show antimutagenic activity [Kolodziej 2011].

Clinical safety data

No side effects were reported in an open multicentre study involving 1487 patients treated for five weeks with 425 mg of a dry extract (5.0-7.1:1) 3 times daily [Pfannkuch 2002].

Hypersensitivity reactions and mild gastrointestinal complaints (in 0.07%-0.3% patients) were the only adverse reactions observed after intake of European goldenrod [Schätzle 1998; Gardner 2013; Edwards 2015].

Two post-marketing studies showed very good or good tolerability in 97-98% of patients (n = 745 and 1487) during 2-4 weeks of treatment. One suspected case of a minor adverse drug reaction (heart burn) was reported [Schmitt 1996; Laszig 1999a,b].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

SYMPHYTI RADIX

2012

Comfrey Root

DEFINITION

Comfrey root consists of the dried rhizomes and roots of *Symphytum officinale* L.

The material complies with the monograph of the Deutscher Arzneimittel-Codex [Beinwellwurzel – Symphyti radix. In: DAC 1979] or the British Herbal Pharmacopoeia [Comfrey Root - Symphyti radix. In: British Herbal Pharmacopoeia 1996].

Fresh material may be used provided that when dried it complies with one of the above monographs.

CONSTITUENTS

Characteristic constituents of comfrey root include: 0.6-4.7% of allantoin [Dennis 1987]; abundant mucilage polysaccharides (about 29%) composed of fructose and glucose units [Franz 1969]; phenolic acids such as cinnamic acid, chlorogenic acid (0.012 %), caffeic acid (0.004%), α-hydroxycaffeic acid and rosmarinic acid (up to 0.02%) [Andres 1991; Grabias 1998; Staiger 2009]; glycopeptides and amino acids [Hiermann 1998]; and triterpene saponins in the form of monodesmosidic and bidesmosidic glycosides based on the aglycones hederagenin (e.g. symphytoxide A), oleanolic acid [Aftab 1996] and lithospermic acid [Wagner 1970].

Pyrrolizidine alkaloids (0.05-0.08%) with 1,2-unsaturated necine ring structures are also present, almost entirely in the form of their *N*-oxides, the main ones being 7-acetylintermedine and 7-acetyllycopsamine together with smaller amounts of intermedine, lycopsamine and symphytine [Brauchli 1982; Mütterlein 1993].

CLINICAL PARTICULARS

Therapeutic indications

External use only
Pain and swelling in muscles and joints [Koll 2002; Koll 2004; Tschaikin 2004; Pabst 2004; Predel 2005; Staiger 2007; Grube 2007; Giannetti 2010], osteoarthritis [Grube 2007; Schulz 2007], acute myalgia in the back [Giannetti 2010], strains, contusions and distortions [Koll 2002; Koll 2004; Tschaikin 2004; Pabst 2004; Predel 2005; Staiger 2007]; epicondylitis, tendovaginitis and periarthritis [Petersen 1993].

Also used for tendinitis syndrome, knee joint injuries, non-active gonarthrosis, insect bites, mastitis, fractures, wound healing and skin inflammation. In these indications, the efficacy is plausible on the basis of long-standing use [Häberle 1952; Briel 1953; Ziolkowski 1957; Korte 1958; Büzberger 1960; Prinzing 1960; Deister 1963; Awang 1987; Koehler 1987; Kothmann 2003; Barnes 2007, Staiger 2009].

Posology and method of administration

Dosage

External use only
Adults and children from 3 years: ointments or other preparations containing up to 35% of root extract (1:2, ethanol 60% V/V), applied 3-4 times daily [Koll 2002; Koll 2004; Predel 2005; Staiger 2005; Staiger 2007; Grube 2007; Staiger 2008; Giannetti 2010].

Some national authorities restrict the external use of comfrey root. The German health authorities, for example, limit the content of pyrrolizidine alkaloids (PA) (including *N*-oxides) with 1,2-unsaturated necine structures in the amount of a preparation to be applied daily to not more than 100 µg. There are no restrictions for preparations containing less than 10 µg PA [Schilcher 2010].

E/S/C/O/P
MONOGRAPHS

Method of administration
For topical application only.

Duration of use
The German health authorities recommend not more than 4-6 weeks per year if the daily application contains between 10 µg and 100 µg of pyrrolizidine alkaloids (including their *N*-oxides) with 1,2-unsaturated necine structures [Teuscher 2009; Schilcher 2010].

Contraindications
None known.

Special warnings and special precautions for use
In cases of wound healing and skin inflammation, PA-free comfrey root preparations should be used.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
As no human data are available, the potential risk is unknown. In accordance with general medical practice the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Anti-inflammatory activity
Rosmarinic acid has been shown to possess anti-inflammatory activity in various test systems. At concentrations ranging from 0.1 to about 10 mM it significantly inhibited the formation of malondialdehyde in human platelets ($p \leq 0.001$ at 1 mM) with an IC_{50} of 3.37 mM [Gracza 1985]. In another study rosmarinic acid inhibited prostaglandin synthesis and carrageenan- and gelatine-induced erythrocyte aggregation. Allantoin had no effect, or no significant effect, on erythrocyte aggregation in these tests [Gracza 1987].

In preparations of rat stomach a glycopeptide isolated from comfrey root dose-dependently inhibited the release of prostaglandins PGE_2 (IC_{50}: 1.47 ng/ml) and PGI_2 (IC_{50}: 1.0 ng/ml), and of 12-HETE (IC_{50}: 3 ng/ml) and arachidonic acid (AA; IC_{50}: 27.0 ng/ml) too. AA- and ADP-induced platelet aggregation was not inhibited by 3 or 10 µg/ml of the glycopeptide [Hiermann 1998].

In a study of the influence of a 60%-ethanolic comfrey root extract on different elements of the human immune system, the extract was found to exert dose-dependent anti-complementary effects on the classical pathway of complement activation (IC_{50}: 1.8 µg/ml), the alternative pathway of complement activation (IC_{50}: 77.8 µg/ml) and the terminal route of complement activation (IC_{50}: 24.0 µg/ml). These activities were correlated with a fraction of molecular weight (MW) > 1,000 kD (IC_{50} values in µg/ml: 0.4, 13.6 and 2.6 respectively). It appears that this fraction interfered with the activity of the complement cascade at the levels of C1 and C3. A dose-dependent decrease in the luminol-dependent chemiluminescence produced by polymorphonuclear leukocytes upon stimulation with opsonized zymosan was also observed (IC_{50} of the root extract: 162.5 µg/ml, IC_{50} of the fraction of MW > 1,000 kD: 163.8 µg/ml) [van den Dungen 1993].

Wound-healing effects
A 40% ethanolic extract from comfrey root and its high MW fraction (> 1,000 kD) were investigated in a test model of wound healing (fibroblasts in a collagen matrix). Both the extract and the fraction dose-dependently inhibited shrinkage of the collagen matrix. Mechanistic and kinetic studies showed a direct interaction of this fraction with collagen and involvement in an early stage of collagen gel contraction. Furthermore, the high MW fraction modified the binding of fibroblasts [van den Dungen 1990; van den Dungen 1993].

Other effects
An 80% ethanolic extract from comfrey root was reported to have antibacterial activity against Gram-positive and Gram-negative bacteria. The effect was 2- to 12-fold weaker than that of gentamicin or tetracycline [Izzo 1995].

An aqueous extract from comfrey root, as well as protein- and carbohydrate-rich fractions isolated from it, stimulated proliferation of neoplastic cells and exerted an antimitotic effect on PHA-stimulated human T-lymphocytes [Olinescu 1993].

Symphytoxide A at 30-300 µg/ml reduced the force and rate of contractions in isolated guinea-pig atria but produced stimulant effects in smooth muscle preparations such as guinea-pig ileum and rat uterus, producing a concentration-dependent contractile response at 10-100 µg/ml. All these effects were abolished in the presence of atropine (80 ng/ml). In frog skeletal muscle preparations symphytoxide A at 100-300 µg/ml produced concentration-dependent contractile responses. No contraction was seen after pre-treatment with d-tubocurarine [Gilani 1994].

In vivo experiments

Anti-inflammatory activity
An orally-administered aqueous extract from comfrey root inhibited carrageenan-induced rat paw oedema, indicating anti-inflammatory activity, and bioactivity-guided fractionation of the extract led to the isolation of a glycopeptide which dose-dependently inhibited oedema formation. After oral administration to rats the ED_{50} of the glycopeptide was 61 µg/kg, whereas the ED_{50} of indometacin was 10 mg/kg under the same conditions [Hiermann 1998].

In another study, oral administration of an 80%-ethanolic extract from comfrey root at 100 mg/kg body weight inhibited carrageenan-induced rat paw oedema by 42%, comparable to the 45% inhibition produced by oral indometacin at 5 mg/kg [Mascolo 1987].

Anti-inflammatory properties of a dry extract from comfrey root were also demonstrated in rats with paw oedema induced by simultaneous injection of carrageenan and prostaglandin E1. The extract (administered intraperitoneally) did not prevent inflammation but it suppressed leukocyte infiltration 3 and 4 hours after induction of inflammation [Shipochliev 1981].

Wound-healing effect
Minced fresh root and an acidic precipitate from an ethanolic

(40% V/V) extract were tested for wound-healing properties in a pig model; both preparations were applied daily on deep dermal burns. Treatment with either preparation resulted in a rigid crust, strongly adherent to the wound bed and the wound-dressing material [van den Dungen 1993].

Pharmacological studies in humans

The effects of dermatological preparations containing 5 or 10% of a comfrey root extract (2:7, 50% ethanol) on the process of healing of experimentally induced UV-B erythema were studied in 29 volunteers in a controlled trial. The anti-inflammatory potency of the extract was found to be equal to or greater than that of diclofenac (no further details available). A positive correlation could be demonstrated between efficacy and the concentration of a caffeic acid derivative in the extract, but not for allantoin [Andres 1989; Andres 1991].

Clinical studies

Five randomized, controlled studies support the therapeutic efficacy of comfrey extracts in the treatment of ankle sprains and complaints of the skeletal and locomotor system, such as osteoarthritis, epicondylitis, tendovaginitis and periarthritis [Petersen 1993; Koll 2004; Predel 2005; Grube 2007; Giannetti 2010]. The results of post-marketing surveillance studies [Koll 2002; Tschaikin 2004; Pabst 2004; Staiger 2008] accord with those of the controlled studies [Staiger 2005; Staiger 2007]. All of the included studies were performed with a comfrey root extract (1:2, ethanol 60%V/V) with less than 0.35 ppm of pyrrolizidine alkaloids in the finished product.

Placebo-controlled studies

The efficacy of an ointment containing 35% of the comfrey root extract was evaluated in a randomized, double-blind, placebo-controlled multicentre study involving 142 patients with a unilateral ankle sprain. Treatment was started within the first 6 hours after injury and continued for 8 days with assessments on days 0, 4 and 7. The affected ankle joint was treated locally with about 2 g of the ointment four times a day. The primary target parameter, tenderness of the ankle joint, was measured by tonometry (difference in tolerated pressure between injured and healthy ankles). During the course of treatment pain in the comfrey extract group regressed significantly more than in the placebo group ($p = 0.0001$). At the final assessment the reductions in tenderness compared to initial values were 2.44 kp/cm^2 in the verum group compared to 0.95 kp/cm^2 in the placebo group. Compared to placebo, the verum treatment showed significant reductions in pressure pain (tonometric method, $p<0.0001$), ankle oedema (figure-of-eight method, $p = 0.0001$), ankle mobility (dorsiflexion, $p = 0.002$; plantar flexion, $p = 0.0116$) and global efficacy ($p<0.0001$) [Koll 2004].

Another randomized, double-blind, placebo-controlled study investigated the effect of the same ointment containing 35% of a comfrey root extract over a 3-week period on 220 patients suffering from painful osteoarthritis of the knee. The primary target parameter was pain relief, assessed by the patient using a visual analogue scale (VAS) to record the reduction in total score from pain at rest and in movement. During the study the total score significantly ($p<0.001$) decreased by 51.6 mm (54.7%) in the verum group and 10.1 mm (10.7%) in the placebo group. The secondary target was improvement in pain, stiffness and functional symptoms as determined by total scores in the WOMAC test (Western Ontario and McMaster Universities). At the end of the study the reduction in the verum group (60.4 mm, 58.0%) and in the placebo group (14.7 mm, 14.1%) was significant ($p<0.001$). Significant improvement in the verum group was also evident with respect to four explorative secondary parameters: SF-36 (quality of life), angle measurement (mobility of the knee), CGI (clinical global impression) and global assessment of efficacy by physicians and patients ($p<0.001$ for each parameter) [Grube 2007, D'Anchise 2007].

The efficacy of the same comfrey ointment was investigated in a multicentre, randomised, double-blind, placebo-controlled clinical trial in patients with acute upper and lower back pain. Over a period of 5 days, 120 patients were treated with 4 g verum or placebo three times daily. The primary efficacy variable was the area under the curve (AUC) of the visual analog scale (VAS) on active standardised movement values assessed on 4 visits. During the treatment, pain intensity on active standardised movement decreased on average (median) by approximately 95.2 % in the comfrey extract group and by 37.8 % in the placebo group ($p<0.001$). Compared to placebo, verum significantly improved secondary efficacy variables (each $p<0.001$): the AUC of the reported back pain at rest, the AUC of the pressure algometry in the trigger point, the global assessment of the efficacy by the patients and investigators, and the functional impaiment measured with the Oswestry disability index (functional impairment)[Giannetti 2010].

In a 4-week pilot study, 41 patients with musculoskeletal disorders (mainly epicondylitis, tendovaginitis and periarthritis) were topically treated with the same ointment ($n = 20$) or placebo ($n = 21$). Efficacy was assessed using several pain parameters: tenderness when pressure applied, pain at rest and during exercise. With respect to "tenderness when pressure applied", the ointment proved superior to placebo in patients with epicondylitis ($n = 7/8$) and tendovaginitis ($n = 6/5$), but not in patients with periarthritis [Petersen 1993].

Comparison with reference drug

The same ointment as above was compared to a gel preparation containing 1% of diclofenac in a randomized, single-blind multicentre study. Patients suffering from acute unilateral ankle sprain (distortion) applied 2 g of either the comfrey ointment ($n = 82$) or the diclofenac gel ($n = 82$) four times daily for 7 ± 1 days. The primary efficacy variable was pain arising from pressure on the injured area, measured with a calibrated caliper (tonometer) on days 0, 4 and 7 and evaluated by the AUC of the pain-time curve; the results indicated that the comfrey ointment was statistically non-inferior, and possibly superior, to the diclofenac gel for the treatment of acute ankle sprain. Results for secondary variables, including the circumference of the joint (swelling, figure-of-eight method), individual spontaneous sensations of pain at rest and during movement (assessed using a visual analogue scale), the use of rescue medication (paracetamol), and evaluations of global efficacy and tolerability by both physicians and patients, also showed equivalence of the comfrey and diclofenac treatments [Predel 2005].

Post-marketing surveillance studies

In a surveillance study, use of the same comfrey ointment was examined in 306 children aged 3 to 12 years. The preparation was applied to children with various conditions such as contusions (61.4%), strains (14.1%), distortions (30.4%) and other indications (6.9%). In the majority of cases the ointment was applied three times daily (57.8%), in others four times daily (26.1%) or twice a day (13.4%). The majority ($n= 281$) were treated for 5 to 8 days. During the observation period symptoms of pain at rest and during the night, pain during motion, tenderness pressure, impaired mobility and general condition improved considerably. The physicians assessed the global efficacy as excellent in 52.3% of cases and good in 44.5 % [Staiger 2008].

In another surveillance study 163 patients applied the same ointment for a variety of conditions, the most frequent being contusions (33% of patients), painful joint complaints (28%),

sprains (26%) and painful muscle complaints (23%). Most patients applied the preparation two (38%) or three (48.5%) times daily and the median duration of treatment was 11.5 days. During the observation period symptoms of pain at rest and during the night, pain during motion, tenderness when pressure applied, impaired mobility, painful muscle complaints and swellings were improved markedly. Morning stiffness of the joints decreased (94%) from 17 minutes initially to 1 minute. The use of non-steroidal anti-inflammatory drugs (NSAIDs) was reduced or discontinued by 13.5% of patients. The physicians assessed global efficacy as excellent in 38.7% of cases and good in 54.6% [Tschaikin 2004].

In a similar surveillance study 162 patients applied a preparation containing 30% of the same comfrey root extract to several conditions such as painful joint complaints (34%), contusions (26.5%) or painful muscle complaints (21.6%). Most patients applied the preparation once (23.5%) or twice (52.5%) daily and the median duration of treatment was 11.8 days. Symptoms of pain at rest and pain during movement, impaired mobility, swelling and painful muscle complaints improved markedly during the observation period. Morning stiffness of investigated joints was decreased by 90% from 20 minutes initially to 2 minutes. The use of NSAIDs was reduced or discontinued by 21% of patients. Global efficacy was assessed by the physicians as excellent in 65.4% of cases and good in 32.7% [Pabst 2004].

Pharmacokinetic properties
No data available.

Preclinical safety data
No data available for the external use of comfrey root.

The pyrrolizidine alkaloids (PAs) in comfrey root are considered to be toxic, especially after oral ingestion [Schoental 1968; Hirono 1978; Schilcher 1982; Brauchli 1982; Schimmer 1983; Mattocks 1986; Behninger 1989; Jaspersen-Schib 1990; Forth 1991; Winship 1991; Röder 1992; Roeder 1995; Michler 1996; Yarnell 1999; Yeong 1990; Yeong 1991; Yeong 1993; Stickel 2000; Mei 2005; Györik 2009; Teuscher 2009; Chen 2010a; Chen 2010b; Liu 2010; Mei 2010; He 2010; Ji 2010; Wiedenfeld 2011].

However, processes are available to remove over 99% of PAs during the production of extracts from comfrey root, enabling preparations for topical application to contain less than 0.35 ppm of pyrrolizidine alkaloids [Grube 2007]. The use of such preparations, as exemplified by the clinical studies summarized above, is considered to have an acceptable level of safety [Schilcher 1982: Schilcher 2010].

Mutagenic activity
A comfrey root extract (1:2, ethanol 60%V/V) was investigated for its ability to induce gene mutations in *Salmonella typhimurium* strains TA 98, TA 100, TA 102, TA 1535 and TA 1537 with and without metabolic activation using the mammalian microsomal fraction S9 mix. The extract showed *no* biologically relevant increases in revertant colony numbers and was not mutagenic in the bacterial reverse mutation assay [Benedek 2010].

Clinical safety data
No major side effects were reported from the clinical studies summarized above involving a total of 1318 patients. The tolerability of topical preparations containing comfrey root extracts was judged to be very good or good in more than 90% of patients The adverse effects related to the study medication were limited to skin reactions (skin redness, eczema, pruritus) and were of mild and moderate severity. [Petersen 1993; Koll 2002; Tschaikin 2004; Pabst 2004; Koll 2004; Predel 2005; Grube 2007; Staiger 2008; Giannetti 2010].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

TANACETI PARTHENII HERBA 2014

Feverfew

DEFINITION

Feverfew consists of the dried, whole or fragmented aerial parts of *Tanacetum parthenium* (L.) Schultz Bip. It contains not less than 0.2 per cent of parthenolide ($C_{15}H_{20}O_3$; M_r 248.3), calculated with reference to the dried drug.

The material complies with the European Pharmacopoeia [Feverfew].

Fresh material may also be used provided that, when dried, it complies with the European Pharmacopoeia.

CONSTITUENTS

The characteristic constituents are sesquiterpene lactones with an α-methylenebutyrolactone structure of which parthenolide, a germacranolide, is the major component. The others, which occur in significantly smaller amounts, are mainly guaianolides including canin, 10-*epi*-canin, tanaparthin-α- and -β-peroxides, artecanin and 8-hydroxyestafiatin [Quick 1976; Bohlmann 1982; Begley 1989; Heptinstall 1992; Dolman 1992].

Other constituents include monoterpenes, principally camphor and trans-chrysanthenyl acetate and polyacetylene compounds (spiroketal enol ethers) [Bohlmann 1982; Knight 1995], lipophilic flavonoids such as 6-hydroxy-kaempferol-3,6-dimethylether and 6-hydroxykaempferol-3,6,4'-trimethylether (= santin), quercetagetin-3,6,3'-trimethylether and quercetagetin-3,6,4'-trimethylether, hydrophilic flavonoids principally apigenin-7-glucuronide and luteolin-7-glucuronide [Williams 1999a; Williams 1999b; Long 2003] and dicaffeoylquinic acids [Wu 2007].

CLINICAL PARTICULARS

Therapeutic indications

Prophylaxis of migraine [Berry 1984; Johnson 1985; Murphy 1988; Heptinstall 1988; Groenewegen 1992; Palevitsch 1997; Ernst 2000; Pfaffenrath 2002; Diener 2005].

Posology and method of administration

Dosage

Adult daily dose: 50 – 120 mg of powdered feverfew [Johnson 1985; Murphy 1988; Ernst 2000; Palevitsch 1997]; 18.75 mg of a supercritical CO_2 extract corresponding to 3 g fresh feverfew [Pfaffenrath 2002; Diener 2005].

Method of administration
For oral administration.

Duration of administration
Treatment for at least 12 weeks is recommended [Groenewegen 1992; Cady 2002; Diener 2005]. If symptoms persist or worsen after 12 weeks, medical advice should be sought.

Contraindications
Hypersensitivity to feverfew or other members of the Compositae [Hausen 1992].

Special warnings and special precautions for use
Abrupt ending of a long-term treatment can provoke withdrawal symptoms, including a rebound of migraine symptoms, anxiety, insomnia as well as muscle and joint stiffness [Johnson 1985].

Interactions with other medicaments and other forms of interaction
None reported.

E/S/C/O/P MONOGRAPHS

No adverse side effects were noted in a large number of individuals taking feverfew together with other medications [Groenewegen 1992].

Pregnancy and lactation
No data available.

In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
In rare cases, allergic contact dermatitis, mouth ulceration or tongue irritation and inflammation may occur [Mitchell 1971; Hausen 1983; De Corres 1984; Turner 1985; Senff 1986; Guin 1987; Mattes 1987; Talaga 1989; Groenewegen 1992; Hausen 1992; Paulsen 2002; Paulsen 2007; Sharma 2007; Killoran 2007; Agarwal 2008; Lakshmi 2008].

Cases of abdominal pain and indigestion in patients who have taken feverfew for long periods have been reported. Rare cases of diarrhoea, flatulence, nausea or vomiting have been noted [Turner 1985; Baldwin 1987; Murphy 1988; Hausen 1992].

Overdose
No toxic effects reported.

Pharmacodynamic properties

In vitro experiments

Much of the biological activity of parthenolide (and the other sesquiterpene lactones) can be explained by the presence of the α-methylenebutyrolactone functional group and its possible interaction with biologically active thiol (sulphydryl) groups [Groenewegen 1986; Heptinstall 1987; Heptinstall 1987b; Groenewegen 1992; Barsby 1992; Sumner 1992; Barsby 1993, Kwok 2001].

There is no firmly established link between the constituents of feverfew and its migraine prophylactic properties. However, many experimental observations, mainly *in vitro*, suggest such a link. Most of these results have been obtained using crude plant extracts although some have been obtained using pure parthenolide or other sesquiterpene lactones from feverfew [Groenewegen 1986; Heptinstall 1987a; Heptinstall 1987b].

Anti-inflammatory effects
Feverfew extracts or pure parthenolide inhibit the production of prostaglandins, which are mediators of inflammation [Groenewegen 1992]. Sesquiterpene lactones having an α-methylenebutyrolactone group are known to have anti-inflammatory activity [Hall 1979].

Feverfew extracts have been shown to inhibit prostaglandin biosynthesis in bovine seminal vesicular mitochondrial fraction, probably by interfering with the action of phospholipase A_2 at the beginning of the arachidonic acid cascade rather than at the cyclo-oxygenase step [Collier 1980; Thakkar 1983; Pugh 1988; Sumner 1992].

Feverfew extracts inhibited thromboxane B_2 and leukotriene B_4 production in leukocytes indicating that they are presumably inhibitors of both 5-lipoxygenase and cyclo-oxygenase [Capasso 1986; Sumner 1992].

An acetone extract of feverfew inhibited phorbol myristate acetate–induced chemiluminescence of human polymorphonuclear leucocytes with an IC_{50} of 0.79±0.19 mg leaf/ml whole blood [Brown 1997].

Parthenolide suppressed inducible nitric oxide synthase (iNOS) promoter activity dose-dependently from 2.5 μM with an IC_{50} of 10μM, thus reducing the formation of NO-radicals. The TPA-induced increase in iNOS promoter activity was also suppressed with an IC_{50} of 2 μM [Fukuda 2000].

A 70% ethanolic extract of feverfew (1:80) and parthenolide (2 μg/ml) inhibited the expression of intercellular adhesion molecule-1 induced by cytokines IL-1 (up to 95% suppression), TNF-α (up to 93% suppression) and IFN-γ (up to 39% suppression) [Piela-Smith 2001].

The LPS-stimulated release of TNF-α and MCP-1 (monocyte chemoattractant protein) in THP-1 human monocytes was significantly inhibited by a 90% ethanolic extract ($p<0.01$) and by a CO_2 supercritical fluid extract ($p<0.05$) [Chen 2007].

Parthenolide was shown to bind to IκB kinase β, the kinase subunit that plays an important role in cytokine-mediated signalling. A biotinylated parthenolide derivative directly inhibited IκB kinase β [Kwok 2001].

Pre-treatment of A549 cells with parthenolide inhibited TNF-α mediated interleukin 8 (IL-8) gene expression ($p<0.05$), activation of the IL-8 promoter ($p<0.05$), translocation of NF-κB and degradation of the NF-κB inhibitory protein [Mazor 2000].

Parthenolide significantly inhibited LPS-induced production of IL-6 and TNF-α by RAW 264.7 cells at 4 μM ($p<0.05$) [Smolinsky 2003].

Parthenolide at 20 μM significantly ($p<0.01$) decreased LPS-induced release of TNF-α (IC_{50} 6.2 μM), IL-1β (IC_{50} 2.5 μM), IL-6 (IC_{50} 5.2 μM) and PGE_2 from peripheral blood mononuclear cells [Shah 2010].

A parthenolide-depleted extract of feverfew (0.026% parthenolide) did not inhibit TNF-α induced NF-κB activity but did inhibit [Sur 2009]:
- the activity of pro-inflammatory enzymes 5-LO, phosphodiesterase-3 and phosphodiesterase-4;
- the release of pro-inflammatory mediators NO, PGE_2 and TNF-α from macrophages and TNF-α, IL-2, IFN-γ and IL-4 from human mononuclear cells;
- the TPA-induced release of PGE_2 from human skin equivalents.

The extract also showed free radical scavenging activity against a wide range of reactive oxygen species. It restored cigarette smoke-mediated depletion of cellular thiols and attenuated the formation of UV-induced hydrogen peroxide [Martin 2008].

In rat peritoneal leucocytes, 6-hydroxykaempferol-3,6-dimethylether and santin inhibited cyclo-oxygenase (CO; IC_{50} 182 and 27 μM respectively) as well as 5-lipoxygenase (5-LO; IC_{50} 182 and 58 μM respectively) in the same way. In contrast, quercetagetin-3,6,3′-trimethylether showed preferential activity against CO, with IC_{50} values of 22 μM for CO and 167 μM for 5-LO [Williams 1999a].

Serotonergic effects
Feverfew extracts inhibit the secretion of serotonin (5-HT)

from blood platelets and also prevent aggregation in response to external chemical stimuli [Groenewegen 1986; Makheja 1981; Makheja 1982]; it is unclear whether phospholipase A2 inhibition is involved in these processes [Groenewegen 1992; Heptinstall 1987a]. The effects on platelets are probably due to the Michael addition mechanism since prior addition of a thiol to the extracts or pure parthenolide removes this bioactivity [Groenewegen 1992; Heptinstall 1987b].

Parthenolide displaced [^{3}H] ketanserin from 5-HT_{2A} receptors from rat and rabbit brain and from cloned 5-HT_{2A} receptors [Weber 1997].

Parthenolide did not show agonistic or antagonistic effects towards serotonin on isolated rat stomach fundus at concentrations from 1 to 10 µM. However, parthenolide non-competitively antagonised the effects of fenfluramine and dextroamphetamine, two indirect acting serotonergics, at a concentration of 10 µM [Béjar 1996].

Similar results were also obtained in another study. Furthermore it was shown that in contrast to parthenolide, a dichloromethane extract of feverfew blocked 5-HT_{2A} and 5-HT_{2B} receptors and neuronally released serotonin at a concentration of 10 µM [Mittra 2000].

Influence on cytochrome P450
An 80% methanolic extract of feverfew inhibited the activity of CYP1A2 (tacrine), CYP2C9 (tolbutamide), CYP2C19 (imipramine), CYP2C8 (paclitaxel), CYP3A4 (midazolam) and CYP2D6 (dextromethorphan) with IC50 values from 53 to 299 µg/ml [Unger 2004].

Antitumour activity
Sesquiterpene lactones with an α-methylenebutyrolactone group, including parthenolide, have been shown to be cytotoxic towards different human tumour cell lines [Lee 1971; Hoffmann 1977]. Parthenolide inhibits the incorporation of thymidine into DNA and thus the cytotoxic activity may occur at the DNA replication level [Woynarowski 1981a, 1981b].

Various studies have demonstrated an antitumour activity for parthenolide by:
- irreversible inhibition of cell growth (mouse fibrosarcoma and human lymphoma) after 24h exposure at concentrations above 5 µM [Ross 1999];
- stimulation of 1,25-dihydroxyvitamin D3-induced differentiation of HL-60 cells via inhibition of NF-κB activity [Kang 2002];
- stimulatory activity on tubulin assembly and by dose-dependent inhibition of the growth of MCF-7 cells [Miglietta 2004];
- induction of mitochondrial dysfunction and apoptosis via Bcl-2 family proteins [Zhang 2004];
- inhibition of proliferation of different cell lines [Wu 2006; Parada-Turska 2007; Parada-Turska 2008; Oghuchi 2009; Weng 2009].

Studies on parthenolide-induced apoptosis and molecular mechanisms confirmed this activity [Won 2005; Zunino 2007; Pajak 2008; Anderson 2008].

Other effects
Parthenolide interferes markedly with both contractile and relaxant mechanisms in blood vessels, almost certainly due to the presence of the α-methylenebutyrolactone functional group; when this is blocked, these activities are lost [Barsby 1992; Barsby 1993].

The lactones and an ethanolic extract showed antimicrobial activity *in vitro*, inhibiting the growth of Gram-positive (but not Gram-negative) bacteria, yeasts and filamentous fungi [Fukuda 2000; Kalodera 1996]. The essential oil was bactericidal and fungicidal against mainly Gram-negative bacteria, yeasts and fungi [Kalodera 1997].

Parthenolide inhibited promastigote growth of *Leishmania amazonensis* with an IC_{50} of 0.37 µg/ml. Parthenolide also reduced the survival index of the amastigote forms by 50% at 0.8 µg/ml [Tiuman 2005].

The epimastigote growth of *Trypanosoma cruzi* was inhibited significantly ($p<0.05$) more by parthenolide than the reference benznidazole. The $IC_{50/96h}$ for parthenolide was 0.5 µg/ml compared to 1.8 µg/ml for benznidazole. The internalization index (number of infected cells x mean of amastigotes per cell) of the amastigote forms was reduced by 50% at 2 µg/ml of parthenolide [Izumi 2008].

An ethyl acetate extract and parthenolide exhibited antiviral activity against *Herpes simplex* 1 with an IC_{50} of 40 µg/ml and 0.3 µg/ml respectively [Onozato 2009].

In vivo experiments

Anti-inflammatory activity
Significant inhibition ($p<0.01$) of collagen-induced broncho-constriction in guinea pigs was obtained after intravenous administration of 1 ml feverfew extract (1 g of chopped fresh leaves in 2.5 ml distilled water) [Keery 1986]. It has been interpreted as a consequence of phospholipase A_2 inhibition. A similar inhibition of prostanoid biosynthesis suggests that parthenolide may suppress the induction of nephrocalcinosis in rats [Groenewegen 1992].

An extract of feverfew, administered orally (10–40 mg/kg b.w.), and parthenolide, administered intraperitoneally (1–2 mg/kg), led to significant anti-nociceptive ($p<0.05$ to $p<0.001$) and anti-inflammatory ($p<0.05$) effects against acetic acid-induced writhing in mice and carrageenan-induced paw oedema in rats respectively. Naloxone failed to reverse the induced antinociception. Higher doses of the extract (up to 60 mg/kg orally) did not alter the locomotor activity, potentiate the pentobarbital-induced sleep time nor change the rectal temperature in rats [Jain 1999].

Parthenolide reduced the phorbol myristate acetate-induced contact sensitivity in the murine ear oedema assay (0.5 mg/ear). Reduced parthenolide lost its activity completely [Kwok 2001].

Mice were exposed daily to UVB light for 10 weeks and treated topically with a 1% solution of parthenolide-depleted feverfew extract pre- and post-UV exposure. The UV-induced epidermal hyperplasia was significantly reduced in the verum group (62.3 µm to 45.4 µm; $p<0.05$). The same solution also reduced UV-induced DNA and cellular damage in porcine skin [Martin 2008].

Topical application of a parthenolide-depleted feverfew extract significantly reduced TPA-induced oedema in mice with an ED_{50} of 0.09%. In another experiment mice were sensitized to oxazolone and one hour after the challenge a parthenolide-depleted feverfew extract was applied at 0.1% and 0.01%. In the verum group the mean biopsy weight was reduced by 70% and 52% respectively (compared to hydrocortisone at 0.1% and 0.01% with a reduction of 77% and 65% respectively). The release of the pro-inflammatory cytokines TNF-α, IL-2 and IFN-γ was also significantly reduced (all reductions $p<0.05$) [Sur 2009].

I.p. administration of parthenolide in rats at 10 mg/kg b.w. for 6 days significantly reduced nitroglycerin-induced neuronal activation in the following brain nuclei: paraventricular nucleus of the hypothalamus ($p<0.03$), parabrachial nucleus ($p<0.05$), nucleus tractus solitarius ($p<0.03$) and nucleus trigeminalis caudalis ($p<0.03$) [Tassorelli 2005].

Anti-ulcerogenic activity
Gastric ulcers induced by oral administration of absolute ethanol to rats were dose-dependently reduced by oral pre-treatment with a chloroform extract of feverfew (2.5–80 mg/kg) or parthenolide (5-40 mg/kg). The protection ranged between 34 and 100% for the extract and 27 and 100% for parthenolide. The mean ulcer index was reduced from 4.8±0.3 (control) to 1.4±0.2 (extract 40 mg/kg) and 0.5±0.1 (parthenolide 40 mg/kg) [Tournier 1999].

Pharmacological studies in humans

Platelet aggregation responses in 10 patients taking feverfew for 3.5 to 8 years were indistinguishable from those of a control group of 4 patients who had stopped taking feverfew at least 6 months previously [Groenewegen 1992; Biggs 1982].

In a double-blind, randomised, placebo-controlled study 12 volunteers were treated topically with a preparation containing parthenolide-depleted feverfew extract (1%) once daily for 2 days before and after exposure to UVB irradiation at varying minimal erythema doses (MED). In the verum group the UV-induced erythema was significantly reduced as shown by cross-polarized photography, by the expert grader assessment ($p<0.05$ at 1 and 1.5 MED UVB dose) and by chromameter readings ($p<0.05$ at 0.5 and 1 MED) [Martin 2008].

Topical treatment of 8 volunteers with a preparation of parthenolide-depleted feverfew extract 30 minutes prior to challenge by methyl nicotinate resulted in a dose-dependent reduction in erythema as measured by apparent haemoglobin content: reduction of 28% ($p<0.01$), 39% ($p<0.05$) and 68% ($p<0.05$) for 0.5%, 0.75% and 1% extract, respectively [Sur 2009].

Clinical studies

In a systematic review, six randomised, placebo-controlled, double-blind trials of feverfew mono-preparations for the prevention of migraine in human subjects were evaluated by the Jadad score [Johnson 1985; Murphy 1988; Palevitch 1997; De Weerdt 1996; Kuritzky 1994; Pfaffenrath 1999]. The review concluded that feverfew is likely to be effective in the prevention of migraine [Ernst 2000].

In a further systematic review by the same authors, 5 randomised, placebo-controlled, double-blind trials (343 patients) met the inclusion criteria [Johnson 1985; Murphy 1988; De Weerdt 1996; Palevitch 1997; Pfaffenrath 2002]. Kuritzky 1994 was excluded from this review and Diener 2005 is not mentioned. Pfaffenrath 2002 describes the same study as Pfaffenrath 1999, cited in the previous review. The authors concluded that there is not sufficient evidence to convincingly suggest an effect of feverfew for preventing migraine [Pittler 2009].

In a double-blind, randomised, placebo-controlled study, an oral dose of 2 x 25 mg of dried feverfew leaf was administered for 6 months to 8 migraine patients, while 9 patients took placebo. All patients had previously treated themselves daily with fresh feverfew leaf for 3-4 years, with substantial alleviation of symptoms. The mean frequency of headaches in the verum group was 1.7 per month during the 6 months and 1.5 per month during the final 3 months, compared with 3.13 and 3.43 respectively in the placebo group ($p<0.02$). Nausea or vomiting, or both, occurred on only 39 occasions in the verum group compared with 116 occasions in the placebo group ($p<0.05$) [Johnson 1985].

In a double-blind, randomised, placebo-controlled, crossover trial in 59 migraine patients, after a 1-month run-in period on placebo (dried cabbage leaf) each patient received feverfew for 4 months then placebo for 4 months (or vice versa). The verum groups received one capsule daily containing 70-114 mg of dried feverfew leaf, equivalent to 0.545 mg of parthenolide. There was a 24% reduction in the number of migraine attacks ($p<0.005$) during feverfew treatment (compared with the placebo phase) and, although no significant change in the duration of individual attacks, a significant reduction ($p<0.002$) in nausea and vomiting during attacks. Global assessments also showed that feverfew was significantly ($p<0.01$) superior to placebo [Murphy 1988].

In another crossover study 57 migraine patients were treated in 3 phases. In the first phase (open) all patients received 100 mg of powdered feverfew leaf per day for 2 months. In the second and third phases, with a randomized, double-blind, crossover design, the patients received feverfew (same dosage) or placebo consecutively, each for an additional month. Compared to placebo treatment, feverfew caused a significant reduction in pain intensity ($p<0.01$) and in the severity of typical symptoms such as nausea, vomiting, sensitivity to light (all $p<0.001$) and sensitivity to noise ($p<0.03$) [Palevitch 1997].

In a randomized, double-blind, placebo-controlled, crossover study, 50 migraine patients received placebo daily for 1 month. Over the following 4 months the patients received 1 capsule daily containing a 90% ethanolic extract of feverfew standardized to 0.5 mg of parthenolide and subsequently placebo for 4 months (or vice versa). No significant prophylactic effect could be demonstrated for the feverfew preparation, but the patients tended to use less of other medications [De Weerdt 1996].

In a double-blind, randomised, placebo-controlled study 147 patients suffering from migraine, with and without aura, were treated for 12 weeks after a 4-week baseline period. Three dosages (2.08 mg, 6.25 mg and 18.75 mg) of a CO_2 feverfew extract (8% parthenolide) administered 3 times daily, were compared with placebo. The primary efficacy parameter was the number of migraine attacks during the last 28 days of treatment (= migraine frequency) compared to baseline. Secondary endpoints included total and average duration and intensity of migraine attacks, and number of days with accompanying migraine symptoms. No significant effect was found for either primary or secondary outcomes. Subgroup analysis including patients with at least four migraine attacks during the baseline period ($n=49$) showed a significant ($p=0.02$) reduction in migraine frequency for the 6.25 mg verum group compared to placebo; with an average of 1.8 less attacks in the final 28 days than during the baseline period [Pfaffenrath 2002].

In a double-blind, randomised, placebo-controlled study, 170 migraine patients (with 4 to 6 attacks within a 4-week baseline period) were treated for 16 weeks with 6.25 mg CO_2 feverfew extract (8% parthenolide) three times daily or placebo. Migraine frequency decreased significantly ($p=0.046$) from 4.8 attacks (baseline period) to 2.9 attacks (mean of second and third 28-day treatment period) compared to 3.5 attacks for placebo [Diener 2005].

Prophylactic effects of feverfew have also been claimed with regard to various forms of arthritis [Groenewegen 1992; Berry

1984; Hausen 1992]. However, a double-blind, placebo-controlled, 6-week study, involving 40 female patients with rheumatoid arthritis receiving either 70-86 mg of dried leaf per day or placebo, showed no beneficial effects [Pattrick 1989].

Pharmacokinetic properties

An *in vitro* study with human intestinal cells (Caco-2) demonstrated a substantial linear transport of parthenolide at 250 µM (compared with propranolol and losartan). This transport was not affected by MK-571, an inhibitor of P-glycoprotein, showing that there is no efflux of parthenolide and suggesting a good bioavailability [Khan 2003].

Parthenolide given to patients at doses of up to 4 mg per day could not be detected in plasma [Curry 2004].

Preclinical safety data

Reproductive toxicity
The theoretical maximum tolerated dose of 12.9 ml/kg/day of a 65.3 mg/ml feverfew solution (20% ethanol; 0.23% parthenolide) was confirmed as non-toxic in a preliminary experiment using incremental dosing by oral gavage in 2 non-pregnant, female rats for 8 days. This dose of feverfew (839 mg/kg/day) was administered to female rats on either gestation days (GD) 1-8 or GD 8-15. Controls received an equivalent dose of ethanol or distilled water. On GD 20, foetuses were weighed and examined for signs of external, internal or skeletal malformations: the liver weight of the verum group in GD 1-8 was significantly ($p<0.05$) lower compared to the ethanol group, but not to the water controls. When rat embryos were explanted and cultured with the extract at concentrations from 1 to 4 µl/ml, malformations and embryotoxicity were demonstrated in a dose-dependent manner [Yao 2006].

Clinical safety data

A systematic review of 6 clinical trials using feverfew mono-preparations for the prevention of migraine led to the conclusion that there are no major safety problems. In two clinical trials, the incidence of adverse effects was actually higher in the placebo groups than in the verum groups [Ernst 2000; Pittler 2009].

Thirty female migraine patients who had taken feverfew daily (12.5-250 mg) for more than 11 consecutive months were compared to a matched control group of 30 female migraine patients who had not used feverfew. No statistically significant difference in the mean frequency of chromosomal aberrations and sister chromatid exchanges in lymphocytes were observed over a period of several months. Urine from feverfew-using migraine patients did not induce a significant increase in the mean number of revertants in the Ames mutagenicity assay (30 ml of urine, concentrated and dosed in 50 ml of DMSO), with or without metabolic activation, in comparison with urine from matched non-using migraine patients [Johnson 1987; Anderson 1988].

Parthenolide given to cancer patients at doses of up to 4 mg per day for 28 days was well tolerated without dose-limiting toxicity [Curry 2004].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books*, ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009,* but are not available online for copyright reasons.

After purchase of a single monograph*,* the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-kB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-b	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

TARAXACI RADIX

2024

Dandelion root

DEFINITION

Dandelion root consists of the whole or cut, dried underground parts of *Taraxacum officinale* F.H.Wigg.

The material complies with the European Pharmacopoeia [Dandelion root].

Fresh material may also be used provided that, when dried, it complies with the European Pharmacopoeia.

CONSTITUENTS

Sesquiterpene lactones including eudesmanolides (tetrahydroridentin B and taraxacolide-1-O- β-D-glucopyranoside), guaianolides (11 β,13-dihydrolactucin and ixerin D) and germacranolides, taraxinic acid and 11,13-dihydrotaraxinic acid, their β-D-glucopyranosyl esters and β-malonylglucopyranosyl esters, as well as ainslioside and ainsliolide; lupane- and euphane-type triterpenes such as 18α,19α-epoxy-21β-hydroxylupan-3-one, officinatrione, 3β-acetoxyeupha-7,24-dien-6-one and others; benzyl glucoside and the phenylpropanoid glycosides dihydroconiferin, syringin and dihydrosyringin; triterpene alcohols and phytosterols, including taraxasterol [Hänsel 1980, Kisiel 2000a, 2000b, Kashiwada 2001, Saeki 2013, Kikuchi 2016, Esatbeyoglu 2017, Jedrejek 2019]; the γ-butyrolactone glucoside ester taraxacoside [Rauwald 1985]; phenols and phenol carbonic acids such as pyrogallol, pyrocatechol, epicatechin gallate, gallic acid, syringic, vanillic and protocatechuic acid; chlorogenic acids, hydroxycinnamic acids e.g. caffeic, ferulic, cichoric, 3-coumaric and 4-coumaric acid; di- and tri-4-hydroxyphenylacetic acid derivatives of inositol [Clifford 1987, Kenny 2014a, 2014b, Jedrejek 2019]; low amounts of flavonoids [Kenny 2014a]; potassium [Vogel 1977], amino acids [Petlevski 2001] and linear inulin-type polysaccharides consisting of β-(2→1) bonded fructofuranose [Schütz 2006, Olennikov 2009, Savych 2021]. The latex was found to contain a serine proteinase (taraxalisin) [Rudenskaya 1998].

All constituent types and amounts are subject to seasonal variation [Hook 1993, Wilson 2001, Petkova 2015, Huang 2020].

CLINICAL PARTICULARS

Therapeutic indications

Restoration of hepatic and biliary function, dyspepsia, loss of appetite, as an adjuvant in minor urinary complaints, increasing the amount of urine to achieve flushing of the urinary tract [Vogel 1977, Weiss 1991, Leung 1996, Teuscher 2020].

Posology and method of administration

Dosage
Adults: 3-5 g of the drug or 5-10 mL of tincture (1:5, ethanol 25% v/v), three times daily [Bradley 1992].

Method of administration
For oral administration.

Duration of use
If symptoms persist or worsen, medical advice should be sought.

Contraindications

Occlusion of the bile ducts, gall-bladder empyema, obstructive ileus [Weiss 1991, Leung 1996].

E/S/C/O/P MONOGRAPHS

Special warnings and special precautions for use

None required.

Interaction with other medicaments and other forms of interaction

None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Dandelion root can produce allergic contact dermatitis [Lovell 1991] due to the presence of the sesquiterpene lactone taraxinic acid β-glucopyranosyl ester [Hausen 1982].

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antioxidant and radical scavenging effects
An 80% ethanolic extract dose-dependently inhibited ADP-induced platelet aggregation with a maximal inhibition of 85% at a concentration equivalent to 0.04 g of dried root per mL of human platelet-rich plasma. A fraction of the extract containing low molecular weight polysaccharides caused 91% inhibition, and a fraction enriched in triterpenes/steroids 80% inhibition, of platelet aggregation, both at a concentration equivalent to 0.04 g of dried root per mL of plasma [Neef 1996].

An ethyl acetate fraction from a methanolic extract scavenged DPPH radicals with an IC_{50} of 33 µg/mL; in the FRAP assay it had an antioxidant capacity of 433.1 Trolox equivalents/g [Kenny 2014a].

A fraction from a methanolic extract at a concentration of 50 µg/mL significantly ($p<0.05$) induced the transcription factor Nrf2 in Huh7 human hepatoma cells [Esatbeyoglu 2017].

Several fractions from an 80% methanolic extract at concentrations from 0.5 to 50 µg/mL significantly ($p<0.05$ to $p<0.001$) prevented lipid peroxidation in plasma treated with hydrogen peroxide/iron and the oxidative damage to plasma protein as well as the changes in the levels of thiol groups and protein carbonylation. These effects were not dose-dependent [Jedrejek 2019].

Anti-proliferative and anti-cancer effects
Apoptosis was induced in a dose dependent manner in Jurkat human leukaemia cells following treatment with an aqueous extract (1:2) at concentrations between 25 and 150 µL/mL with an IC_{50} value of approximately 100 µL/mL [Ovadje 2011].

An aqueous dry extract (yield 7.34%) induced apoptosis and autophagy in chronic myelomonocytic leukaemia cell lines (MV-4-11, HL-60, U-937) in a dose- and time-dependent manner via late DNA fragmentation and early activation of initiator caspase-8 respectively [Ovadje 2012].

At 200 µg/mL, a 70% methanolic extract significantly ($p<0.01$) reduced cell viability of HepG2 cells and activated AMPK. Apoptosis was proven via downregulation of Bcl-2, up-regulation of BAX and a decrease in the Bcl-2/BAX ratio. A reduction of procaspase 3 and PARP1 cleavage was observed [Rehman 2017].

Anti-diabetic and anti-adipogenic effects
Treatment of differentiating human primary visceral adipocytes with an aqueous extract (5-70 µg/mL) for 10 and 20 days resulted in a dose-dependent reduction of cell viability. At 70 µg/mL the inhibition was 52.5% after 10 days and 44.7% after 20 days. At 30 µg/mL, triglyceride accumulation in the cells was reduced [Colitti 2016].

In HepG2 cells, an aqueous extract (yield 12.1%) at a concentration of 50 µg/mL significantly ($p<0.05$) increased the uptake of the fluorescent glucose analogue 2-(n-(7-nitrobenz-2-oxa-1,3-diazol-4-yl) amino)-2-deoxy¬glucose as compared to control [Juee 2020].

An aqueous extract (yield 24.9%; 64 mg/g polysaccharides) at 500 µg/mL inhibited α-glucosidase by 78.3% and α-amylase by 77.0%. In insulin-resistant HepG2 cells, the reduced glucose consumption and synthesis of intracellular glycogen were significantly ($p<0.05$) improved. The decreased activity of hexokinase and pyruvate kinase in these cells was significantly ($p<0.05$) increased [Li 2021].

Other effects
A methanolic extract (not further specified) showed strong inhibitory activity towards the formation of leukotriene B_4 from activated human neutrophils (90% inhibition at 3 µg/mL). The butanol-soluble fraction of the extract inhibited leukotriene B_4 formation by 86% at 3 µg/mL, while ethyl acetate- and water-soluble fractions displayed only weak activity (32 and 21% inhibition at 3 µg/mL respectively) [Kashiwada 2001].

Addition of 10% of an infusion (30 g root in 100 mL boiling water) to a broth medium of *Bifidobacteria* resulted in a significantly ($p<0.05$) better growth of six *Bifidobacteria* strains, the growth of two strains was slightly inhibited and one of six strains was not changed [Trojanová 2004].

In human embryonic kidney cells (HEK 293), the intracellular Ca^{2+} levels were dose-dependently increased by an ethanolic extract (not further specified) at concentrations of 10-400 µg/mL in the presence of extracellular Ca^{2+}. The extract also induced the release of Ca^{2+} from the endoplasmic reticulum and stimulated the activity of phospholipase C [Gerbino 2018].

An aqueous extract (yield 11.5%) at 5 µg/mL significantly ($p<0.05$) reversed the heavy metal (Cd, Ni, As, Cu)-induced antibiotic resistance of kanamycin and ampicillin against *E. coli*. The Cd-induced increased activity of β-lactamase and of acetyltransferase was significantly reduced ($p<0.05$) by the extract [Yang 2020].

Different fractions from an 80% methanolic extract enriched with sesquiterpene lactones (A and B), hydroxyphenylacetic acids (C), chlorogenic acids (D) or hydroxycinnamic acid derivatives (E) at 10 and 50 µg/mL significantly ($p<0.001$) inhibited adhesion of resting platelets to collagen, and lipid peroxidation in platelets treated with hydrogen peroxide/iron. Adhesion of thrombin-activated platelets to collagen or fibrinogen and of ADP-activated platelets to fibrinogen was most potently reduced by fractions C, D and E. In contrast, the most potent inhibitory effect on the aggregation of ADP-stimulated platelets was observed with fractions A, B and C [Lis 2019].

Taraxinic acid β-D-glucopyranosyl ester inhibited HIV-1 replication in acutely infected H9 cells with an IC_{50} of 1.68 µg/mL. The compound was slightly toxic against uninfected H9 cell growth with an IC_{50} of 7.94 µg/mL [Kashiwada 2001].

In vivo experiments

Hepatoprotective effects
In male Swiss mice exhibiting liver damage induced by permethrin (96 mg/kg/day p.o.), the effects of supplementing their diet with 2% root powder (corresponding to 5 g/kg b.w./day) for 14 days were studied. Increased liver weights and water intake were noted

after permethrin ingestion, which were significantly ($p<0.001$) reduced towards normal by the supplementation. Significant ($p<0.01$ to $p<0.001$) ameliorating effects were also observed in the plasma against the increases of ALT, AST, LDH and ALP activities and the bilirubin level. In the liver, supplementation normalised the increased MDA, GSH and GPx levels, and also reduced SOD levels (all $p<0.001$) and improved the vacuolisation, congestion and condensed nuclei induced by permethrin [Ghorbel Koubaa 2020].

For 7 days Wistar rats were orally administered with a 70% ethanolic extract (not further specified) at 50 and 100 mg/kg b.w./day or a hepatoprotective herbal combination consisting of 8 components at 56 mg/kg/day as control. Liver damage was induced by 1.5 mL CCl_4 i.p. 6 hours after the last dose and the animals were sacrificed on day 8. The CCl_4-induced decreased concentrations of SOD, CAT, glutathione and peroxidase in the liver were significantly ($p<0.001$) restored by the higher dose of extract when compared to control and comparable to the herbal combination. The increased MDA concentration was significantly ($p<0.01$) attenuated by the higher extract dose as compared to control and was also comparable with the herbal combination [Sumanth 2006].

In male ICR mice, liver damage was induced with ethanol (5 g/kg b.w./day by gavage for 8 days). One group received 1 g/kg/day of a lyophilised hot water extract (1:20) by gavage 30 min before ethanol administration. The extract significantly reduced the ethanol-induced elevated levels of ALT, AST, ALP and LDH in the serum (all $p<0.05$). The reduction of the activities of CAT, GST, GPx and glutathione reductase as well as of the concentration of GSH in the liver due to ethanol were normalised by the extract (all $p<0.05$). The increase of MDA in the liver was also significantly ($p<0.05$) attenuated [You 2010].

Hepatic fibrosis was induced by i.p. administration of CCl_4 (20% in olive oil, 2 mL/kg) twice a week for 4 weeks in male BALB/c mice. For the following 10 days, the animals received a tincture (4:1; 12% ethanol) at i.p. doses of 200 and 600 mg/kg b.w./day. The tincture significantly ($p<0.05$) reduced the CCl_4-induced increases in weight gain, relative liver weights and hydroxyproline content (as a marker of the degree of fibrosis in the liver). The elevated serum ALP activity was decreased with the high dose and the reduced SOD activity was normalised at both doses. In contrast, increased AST and ALT activities remained unchanged. The tincture reduced hepatic fibrinous deposits, restored the histoarchitecture of the livers, modulated the expression of glial fibrillary acidic protein and α-smooth muscle actin and increased metallothionein I/II in the liver [Domitrović 2010].

The effects on CCl_4-induced hepatic injuries of a crude ethanolic extract (yield 22%), and an ethyl acetate (0.42%) fraction enriched in two sesquiterpene lactones, were studied. Male Swiss albino mice received either the extract at 150 mg/kg b.w. or the fraction at 20 mg/kg b.w. for 7 seven days as pre-treatment before intoxication (pre-treatment; single dose of 20 µg/kg i.p. CCl_4) or for 7 days after intoxication (post-treatment; single dose of 20 µg/kg i.p.CCl_4). The increase of total bilirubin and the decrease in total protein, as well as the elevated activity of AST, ALT and ALP in the serum, due to CCl_4 were significantly ($p<0.05$) improved by all treatments compared to control. CCl_4-induced increases in liver weight, liver protein and lipid peroxidation were significantly ($p<0.05$) reduced, and the depletion of reduced glutathione in the liver was restored ($p<0.05$) by both pre- and post-treatment; post-treatment was slightly more effective. Histological examination showed significant liver protection in mice post-treatment with the extract and in both pre- and posttreatment with the fraction [Mahesh 2010].

In male Wistar rats, injuries in hepatic and testicular tissues were induced by irradiation with 8.5 Gy γ-rays, resulting in increases in oxidative markers (MDA, protein carbonylation) and decreases in antioxidant markers (GSH, SOD, GPx, CAT) in both tissues compared to control (all $p<0.001$). Oral treatment with 200 mg/kg b.w./day of an aqueous extract (not further specified) for 14 days before irradiation or 14 days after irradiation led to significant ($p<0.001$) improvements of these parameters as compared to only irradiated animals. The extract also positively modulated the irradiation-disturbed activities of purine nucleoside phosphorylase, glutamate dehydrogenase and glutathione-S-transferases in serum as well as of ALT, AST and ALP in the liver; levels of LDH and albumin in the liver were largely restored, and those of IL-1β, TNF-α and caspase-3 were reduced (all $p<0.001$ as compared to irradiated rats). A significant improvement of serum levels of testosterone, inhibin B and FSH, as well as testicular Zn and steroidogenic acute regulatory protein, and cholesterol side-chain cleavage enzyme *P450scc* gene expression were observed (all $p<0.001$). Histopathological changes in the hepatic and testicular tissues following irradiation were ameliorated. The improvements of most parameters were slightly better by pre-treatment with the extract as compared to the treatment after irradiation [Abdel-Magied 2019].

Chronic liver failure was induced in male Wistar rats by s.c. administration of human serum albumin, this was followed by oral treatment with an extract (70% ethanol; yield 15.2%) at doses corresponding to 50, 100 and 200 mg of the root/kg b.w. daily for 7 days. Acute on chronic liver failure (ACLF) was induced on day 8 with D-galactosamine (700 mg/kg i.p.) and LPS (10 µg/kg i.p.). The extract significantly decreased the elevated markers of liver injury (AST, ALT, ALP, γ-glutamyltransferase, total bilirubin; all $p<0.001$), renal markers (creatinine, urea; $p<0.001$) and parameters of oxidative stress (total oxidative stress, oxidative stress index, MDA, NO, 3-nitrotyrosine: all $p<0.001$; total thiols; $p<0.01$) in serum as compared to untreated ACLF rats. Histopathology showed significantly ($p<0.001$) reduced hepatic injuries in all extract groups compared to the untreated ACLF group [Pfingstgraf 2021].

In male ICR mice, liver damage was provoked by an i.p. injection of 400 mg/kg b.w. of paracetamol. Six hours after paracetamol the animals were treated with polysaccharide fractions DPR1 or DPR2 from the root (50, 100 or 200 mg/kg i.p. three times daily for two days). N-Acetylcysteine (120 mg/kg) served as positive control. The paracetamol-induced injuries in liver tissue (haemorrhages, necrosis, neutrophil infiltration) were attenuated by all doses of both fractions to an extent comparable with the positive control. Paracetamol-induced elevated serum AST levels and oxidative stress markers in the liver (ROS, MDA) were significantly ($p<0.01$) and dose-dependently reduced by DRP1 and DRP2. Both fractions at 100 and 200 mg/kg significantly ($p<0.01$) reversed the paracetamol-induced changes in liver antioxidant enzyme activities. These effects were mediated by the Nrf2-Keap pathway [Cai 2017].

Metabolic effects

Male rabbits were fed a high-cholesterol diet (250 g/day) with or without 1% dried root for 4 weeks. The high fat diet increased liver weight and the serum concentrations of AST and ALT as well as plasma concentrations of TC, LDL-C, triglycerides and phospholipids. Only the elevated ALT and triglyceride concentrations were significantly ($p<0.05$) reduced by the supplementation. Increased LDL and phospholipids were further augmented by the root. No effect on decreased HDL was observed. The supplementation significantly ($p<0.05$) attenuated the effects of the high fat diet on GSH, GST, GPx, CAT, SOD and TBARS in the liver. In the aorta, atherosclerotic lesions were reduced and increased wall thickness was significantly ($p<0.05$) decreased [Choi 2010].

Crossbred (PL x PLW) x Duroc pigs with an initial body weight of 25.0 kg received a diet containing 4% root powder until reaching a body weight of 115 kg. As compared to controls without supplementation, the animals at a weight of 50 and 100 kg showed significantly ($p<0.05$) lower TC and LDL plasma concentrations and the highest percentage of the HDL fraction at both fattening periods. Significantly ($p<0.05$) less cholesterol was observed in backfat, the Longissimus dorsi muscle and the liver. Beneficial effects on several parameters of the fatty acid composition of the heart, liver and Longissimus dorsi reached significance as well ($p<0.005$) [Grela 2014].

Aqueous and 80% ethanolic extracts, administered orally to mice at the equivalent to 25 g of dried root per kg b.w., showed no hypoglycaemic activity in oral glucose tolerance tests [Neef 1995].

In alloxan-induced diabetic Swiss albino mice, oral administration of an aqueous extract (yield 12.1%) at doses of 200 and 400 mg/kg b.w. dose- and time-dependently reduced blood glucose levels. The strongest effect was observed after 5 hours with 40.4% and 62.3% reduction respectively. No significant effects were observed in a s.c. glucose tolerance test [Juee 2020].

Anti-inflammatory effects
A dry 80%-ethanolic extract inhibited carrageenan-induced rat paw oedema by 25% when administered orally at 100 mg/kg b.w. one hour before oedema elicitation, compared to 45% inhibition by indomethacin at 5 mg/kg [Mascolo 1987].

In another experiment, carrageenan-induced rat paw oedema was partially inhibited following i.p. administration of 100 mg/kg b.w. of an extract (42% after 3 hours and 29% after 5 hours) [Tita 1993].

A dry methanolic extract (not further specified), at a concentration of 1 mg per ear topically applied 30 min before challenge with TPA, inhibited mouse ear oedema by 51% as compared to indomethacin with 96% inhibition at the same dose [Yasukawa 1998].

Female C57BL/6 mice with ulcerative colitis induced by 2% dextran sodium sulphate (DSS) in their drinking water received a hot water extract (yield 15%; 20 mg/kg b.w. p.o.) twice daily for 10 days. The extract improved the progressive body weight loss and disease severity index from day 3, significantly on day 10 ($p<0.01$) as compared to DSS. The shortening of colon length after DSS was restored ($p<0.01$). The higher histological scores for several parameters of tissue damage and inflammation were ameliorated ($p<0.01$). Elevated inflammatory cytokines (TNF-α, IL-6, IL-1β), MPO activity, ROS (all $p<0.001$) and MDA ($p<0.05$) in the colon were significantly reduced. The decreased SOD activity was improved [Ding 2018].

Ulcerative colitis was induced in male and female C57BL/6 mice by addition of 2% DSS to their drinking water for 10 days. In parallel, mice were treated by gavage with a dry extract (ethanol; 1:10) at doses of 0.5, 1 or 2 mg/mouse/day. Sulfasalazine (100 mg/kg b.w./day) served as positive control. The extract dose-dependently reduced the colon mucosal damage index, significant at the highest dose ($p=0.03$). In histopathology, only mild epithelial cell degeneration and necrosis, as well as low numbers of inflammatory cells, were observed in colonic sections of animals receiving sulfasalazine or the high extract dose. Both these treatments also attenuated the DSS-induced changes in TNF-α, IL-6, IL-1β and IL-10 as well as oxidative injuries in serum and colon tissues. The reduced SOD activity was increased and the enhanced PAF, PGE_2 and MPO levels were decreased. The DSS-induced high phosphorylation level of ERK, JNK or p38 in colon tissues was blocked. The extract at the highest dose also completely reversed all alterations in the phosphorylation levels of NF-κB p65 and IκBα, in the abundances of IκBα and p65 in the cytoplasm and in the production of NF-κB and p65 in nuclei. All effects of the extract were reversed by the MAPK agonist, BIM-23A760 [Zhou 2022].

Anti-tumour effects
Female Wistar albino rats aged 50 days received a single oral dose of 7,12-dimethylbenz(α)anthracene (DMBA) to induce breast cancer. Four months after the administration of DMBA, one group was orally treated with 500 mg/kg b.w./day of an aqueous dry extract (not further specified) for 4 weeks. The animals were killed 5 months after DMBA administration. The elevated levels of serum cancer antigen 15-3 after DMBA were almost normalized by the extract. The DMBA-induced up-regulation of the mRNA expression of *Pdk1*, *Akt1*, *Pik3r1*, *Erbb2*, *Plk3ca* and *Map3kr1* was significantly ($p<0.05$) reduced by the extract as compared to the DMBA group. The excessive proliferation of the lining epithelium of acini and ductules with hyperchromatic nuclei and excessive immunostaining of Bcl2 in the mammary gland tissues after DMBA was ameliorated by the extract. The average tumour weight was reduced to approximately one third by the extract in comparison to DMBA [Nassan 2018].

Immunocompromised 6-week old CD1 nu/nu mice were s.c. injected with prostate cancer cells (DU-145, PC-3) in the hind flanks. After tumour formation, mice received an aqueous extract (not further specified) at a dose equivalent to 40 mg/kg/day in their drinking water for 8 weeks. Tumour volume and weight were significantly reduced as compared to controls receiving water ($p<0.0001$ for DU-145 xenografts and $p<0.01$ for PC-3 xenografts). Body weight gain measured twice a week during the 8 weeks did not differ from control [Nguyen 2019].

Choleretic effect
A decoction from fresh root (equivalent to 5 g of dried plant), administered intravenously to dogs, doubled the volume of bile secreted from the liver during a 30-minute period [Chabrol 1931].

Other effects
Male Swiss albino mice infected with cercariae of *Schistosoma mansoni* were left untreated or received orally either praziquantel (I-PQZ; 500 mg/kg b.w. for 2 days) or root powder (I-Dn; 300 mg/kg for 7 weeks) or the combination of the two medications (I-PQZ+Dn), all starting 45 days after infection. At the end of the experiment, the worm burden in the treated groups was significantly ($p<0.001$) reduced by 93.3% (I-PQZ), 53.1% (I-Dn) and 96.2% (I-PQZ+Dn) as compared to untreated controls. All treatments also resulted in significant decreases in the mean egg counts in the liver and the intestine, in mature and immature eggs, as well as an increase in dead eggs and a reduction in the number and diameter of hepatic granulomas (all $p<0.001$). The elevated levels of IL-6 and TNF-α as well as AST and ALT activities in infected mice were significantly ($p<0.05$) reduced by all treatments. All parameters produced better results with the combination than with PQZ alone [Atwa 2022].

No consistent pattern of diuresis was observed with various extracts (petroleum ether, chloroform or methanol) and their fractions when administered to mice at a dose of 50 mg/kg. Some extracts showed natriuretic and kaliuretic effects related to the potassium content of the roots [Hook 1993, Tita 1993].

Golden Pompano fish (*Trachinotus ovatus*) were fed a diet supplemented with an extract containing 50% polysaccharides at doses of 0, 0.5, 1, 2, 4 and 10 g/kg b.w. for 8 weeks. The highest final body weight, weight gain rate, specific growth rate, feed intake and protein deposit rate were observed with 1 g/kg and the highest feed and protein efficiency ratio with 0.5 g/kg supplementation (all $p<0.05$). Significant increases in plasma total

protein, ALP, complement 4, lysozyme and IgM content as well as decreases in triglycerides and LDL cholesterol were determined in all groups (all $p<0.05$) as compared to control. Hepatic SOD, total antioxidant capacity, CAT, GPx and glutathione reductase were augmented and MDA reduced, whereas the influence on these parameters in the plasma was less. After challenge with *Vibrio harveyi*, significantly ($p<0.05$) higher survival rates were observed in fish receiving supplementation [Tan 2017].

Using the same experimental set-up, increases of intestinal antioxidant parameters (SOD, CAT, total antioxidant activity) and a reduction of intestinal MDA were observed. Intestinal morphology was improved as shown by increased muscle thickness, villus length, width and number in the fore- and hindgut as well as muscle thickness and villus width in the midgut. An enhancement of the intestinal barrier function was observed by the increase of zo-1 and occludin mRNA levels and the decrease of claudin-12 and claudin-15 mRNA levels. Improved intestinal immunity was deduced from increased goblet cell numbers and the regulation of the expression of immune-related genes [Tan 2018].

In another study, Golden Pompano fish received a diet supplemented with 0, 0.5 or 1 g/kg b.w. of the same extract for 8 weeks. Weight gain rate and feed intake as well as transcription levels of GPx and IL-10 in the spleen were significantly ($p<0.05$) increased by the higher dose. No significant effects on growth factor β-1, glutathione reductase and CAT in the spleen were observed. The supplementation led to an augmentation of the relative abundance of *Actinobacteria* and *Firmicutes* and a reduction of pathogenic bacteria such as *Mycoplasma*, *Acinetobacter* or *Vibrio* in the gut microbiota. Intestinal goblet cell numbers were increased and epithelial lymphocyte numbers were decreased [Tan 2020].

The effects of an extract (80% ethanol; yield 13%; 200 mg/kg b.w./day p.o.) against doxorubicin (DXR)-induced cardiotoxicity and haematological changes were studied in male Wistar albino rats for four weeks. In the third and fourth week DXR (2.5 mg/kg) was injected 3 times weekly. The DXR-induced changes in red blood cells, total leukocytic count, monocytes, granulocytes and lymphocytes as well as in cardiac biomarkers (creatinine kinase MB, LDH, troponin I, atrial and B-type natriuretic peptide) and cardiac oxidative parameters (MDA, GSH, SOD) were attenuated by co-administration of the extract. Semiquantitative scoring of histopathological lesions due to DXR showed ameliorative effects of the extract [Gad El-Karim 2019].

To evaluate the potential of a 70% ethanolic extract (not further specified) against adverse effects of sodium benzoate (SB), Wistar rats were treated i.p. daily for 14 days with the following: (i) saline (control), (ii) 200 mg/kg b.w. SB, (iii) 200 mg/kg/day SB + 40 mg/kg extract 30 min after SB, (iv) 600 mg/kg SB or (v) 600 mg/kg SB + 40 mg/kg extract 30 min before SB. Messy fur, anxiety and mortality were observed in groups (iv) and (v) (20 and 10% respectively) as well as apathy in group (iv) and aggression in group (v). Group (ii) showed no behavioural changes, but in some animals of group (iii) aggression and anxiety occurred. Analysis of urinary parameters resulted in decreased pH as well as increased nitrite, proteinuria, ketonuria and bilirubin excretion in groups (ii) and (iv) as compared to control. Co-treatment with the extract improved all parameters. The high SB dose caused anaemia, neutropenia and thrombocytopenia as shown by decreased red blood cell count, haemoglobin concentration, number of segmented and unsegmented neutrophils among numerous other parameters. Addition of the extract ameliorated the effects of 600 mg/kg SB. Structural changes in hepatocytes were only induced in group (iv) and improved by the extract in group (v) [Suljević 2022].

Wistar albino rats consumed on average 39.4 mL/day of a decoction (3 g root/300 mL water) or drinking water for 4 weeks. In a perfusion model using isolated hearts, no differences were observed in the minimum and maximum rate of left ventricular pressure development, systolic and diastolic left ventricular pressure, heart rate and coronary flow. Markers of oxidative status in the blood differed significantly ($p<0.05$) from the water control: the H_2O_2 concentration, lipid peroxidation index and reduced glutathione activity were increased whereas superoxide anion radical, SOD and CAT concentrations were reduced [Radoman 2023].

The cardioprotective effects of a methanolic extract were studied in male Wistar rats in a model of ischaemia-reperfusion (I/R) injury-induced myocardial dysfunction. The extract was administered i.p. at daily doses of 50, 100 or 200 mg/kg b.w. for 7 days, and 24 hours after the last dose, in the perfusate 10 min before and during ischaemia and during 40 min of reperfusion. Two other groups received the extract for 7 days and either 30 µM L-NAME or 10 µM glibenclamide in the perfusate 10 min before and during ischaemia and during 40 min of reperfusion. Pretreatment with the extract significantly ($p<0.001$) and dose-dependently attenuated I/R injury-induced increases in the release of LDH and creatine kinase in the coronary effluent and of TBARS in heart tissue, as well as the reduced levels of GSH, total protein and CAT. The significant ($p<0.01$ to $p<0.001$) reduction of myocardial infarction weight and volume was also dose-dependent. In isolated hearts, the reduced coronary flow rate and heart rate were improved by the extract. The NOS inhibitor L-NAME reversed all effects of the extract whereas the K(ATP) channel blocker glibenclamide exhibited only a weak effect [Sharma 2023].

Clinical studies

No published clinical data are available.

Pharmacokinetic properties

The effects of the root on plasma levels of the irreversible tyrosine kinase inhibitors dasatinib, imatinib and nilotinib were studied in male Wistar rats. The animals were treated by gavage with the inhibitors at doses of 25 mg/kg b.w. or the suspension of root powder at 500 mg/kg plus 25 mg/kg dasatinib, imatinib or nilotinib 30 min later. No differences in the main pharmacokinetic parameters were observed in the co-treatment with imatinib or nilotinib. Co-administration of the root and dasatinib resulted in a decrease of the bioavailability of the inhibitor as compared to dasatinib alone. This was shown by significant ($p<0.05$) reductions of C_{max}, AUC_{0-t} and $AUC_{0-\infty}$ by approximately 50% via an inhibitory effect on CYP4A3 and P-gp. In addition, the clearance of dasatinib nearly doubled [Alzoman 2019].

Preclinical safety data

The intraperitoneal LD_{50} of a fluid extract (1:1) was determined as 36.6 g/kg b.w. in mice [Rácz-Kotilla 1974].

A dry ethanolic extract showed low toxicity in mice and rats at doses up to the equivalent of 10 g (oral) and 4 g (intraperitoneal) of dried drug per kg b.w. [Tita 1993].

I.p. administration of a tincture (4:1; 12% ethanol) at a dose of 600 mg/kg b.w./day to BALB/c mice for ten days did not result in any differences in body weight gain, liver weights, serum AST, ALT, ALP, SOD, liver hydroxyproline content, liver histopathology and tissue expression of glial fibrillary acidic protein, alpha-smooth muscle actin and metallothionein I/II [Domitrović 2010].

In Wistar rats of both sexes, no signs of toxicity were observed in behaviour and physical appearance for 30 min after a single oral dose of 5 g/kg of a 70% ethanolic extract and during an additional observation period of 14 days [Aremu 2019].

Single oral doses of 2 g/kg b.w. of a petroleum ether, a chloroform,

a methanol and an aqueous extract (yields 1.5, 0.6, 19.4 and 12.1% respectively) were administered to female albino mice. The extracts did not cause any changes in general behaviour or physical activity over 7 days [Juee 2020].

Male Wistar rats were treated orally with a dry aqueous extract at doses equivalent to 1.84 or 3.68 g root/kg b.w. for 60 days. The extract at the higher dose significantly ($p<0.001$) reduced body weight gain. The weight of testes ($p<0.01$) and of seminal vesicles as well as the concentration and motility of sperms (all $p<0.001$) were significantly decreased at both doses as compared to control. Serum testosterone concentration and the percentage of pregnancies after mating were also decreased by both doses when compared to control, with the high dose reducing the number of foetuses to 0. The rate of morphological abnormalities of sperms significantly increased ($p<0.001$). Rat testicular histology showed late maturation arrest with reduced germinal epithelium thickness and interstitial cells after the low dose and severe disruptions in the architecture of seminiferous tubules, early mutation arrest and germ cell hypoplasia after the high dose. The spermatogonial stem cell self-renewal and proliferation genes *gfr1*, *mcsf* and *plzf* were also influenced by both doses [Tahtamouni 2017].

Clinical safety data

In a patch test, seven patients (2F;5M) with suspected dandelion dermatitis reacted positive to a root extract (equivalent to 1% of plant material in yellow petrolatum) [Lovell 1991].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (well-established use) or on experience and historical use of that product (traditional use) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

TILIAE FLOS

Lime Flower

2022

DEFINITION

Lime flower consists of the whole, dried inflorescence of *Tilia cordata* Miller, *Tilia platyphyllos* Scop., *Tilia × vulgaris* Hayne or a mixture of these.

The material complies with the monograph of the European Pharmacopoeia [Lime flower, Ph. Eur.].

Tilia x europaea L. is the currently accepted synonym of *Tilia x vulgaris* Hayne [Tutin 1968, Medicinal Plant Names Services 2021].

CONSTITUENTS

The characteristic constituents include:

- Flavonoids (ca. 1%), principally glycosides of quercetin, such as isoquercitrin, hyperoside and rutin, and of kaempferol, especially tiliroside among others [Toker 2001; Karioti 2014; Ziaja 2020].
- Proanthocyanidins of various degrees of polymerisation (DP) including dimeric procyanidins B2 and B4, a prodelphinidin trimer and procyanidin oligomers and polymers with DP 3 to 14 [Karioti 2014; Ropiak 2016; Symma 2020; Ziaja 2020].
- Phenolic acids such as chlorogenic acid, caffeic acid, p-coumaric acid and protocatechuic acid [Karioti 2014; Teuscher 2016; Ziaja 2020].
- Mucilage polysaccharides (3-10%) composed of D-galactose, L-rhamnose, L-arabinose, minor amounts of D-xylose, D-mannose and D-glucose as well as D-galacturonic acid and D-glucuronic acid [Kram 1983, 1985; Schmidgall 2000].
- Essential oil (0.02-0.08%) consisting of up to 100 compounds including monoterpenes such as linalool and geraniol, phenylpropanes like eugenol and anethole, sesquiterpenes e.g. farnesyl acetate and hexahydrofarnesyl acetone, aliphatic hydrocarbons including heneicosane, tricosane, pentacosane as well as 2-phenylethanol, its esters and nonanal and nonanoic acid [Buchbauer 1992a, 1992c; Toker 1999; Fitsiou 2007; Kosakowska 2015; Kowalski 2017; Kelmendi 2020].
- Alkaloids of the 3,4-dihydro-2H-pyrrole-type (tiliines A and B), piperidine-type (tiliamines A and B) and 3-O-acetylated piperidine-type (tilacetines A and B) [Symma 2021].
- Coumarins (e.g. scopoletin, fraxetin-8-β-D-glucoside) [Teuscher 2016].

CLINICAL PARTICULARS

Therapeutic indications

Feverish colds and cold-related cough, upper respiratory catarrh, restlessness [Bradley 1992; Barnes 2007; Teuscher 2016; Bertram 2018].

Efficacy in these indications is plausible on the basis of human experience and longstanding use.

Posology and method of administration

Dosage

Adults and children over 4 years
Three times daily: 2-4 g dried drug in infusion or equivalent preparations [Bradley 1992; Teuscher 2016; Bertram 2018]; liquid extract (1:1, 25% ethanol) 2-4 mL; tincture (1:5, 25% ethanol) 4-10 mL [Bradley 1992].

Method of administration
For oral administration.

E/S/C/O/P
MONOGRAPHS

Duration of administration
No restriction.

Contra-indications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available.

In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Some allergic reactions have been reported including allergic rhinitis after consuming a tea. In topical application, urticaria occurred after using a shampoo containing lime flower extract and contact dermatitis in cosmeticians preparing herbal beauty products. In skin prick tests to aeroallergens, sensitisation prevalence was described [Picardo 1988; De Smet 1993; Mur 2001; Rudzki 2003; Krakowiak 2004; Yazicioglu 2004; Loureiro 2005].

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antioxidant and radical scavenging activities
In various assays including DPPH, ABTS, Fe^{2+}/ascorbate-induced lipid peroxidation and carotene bleaching, radical scavenging or antioxidant activities were shown for several aqueous, methanolic or hydroethanolic extracts [Choi 2002; Katalinic 2006; Duda-Chodak 2011; Albayrak 2012; Aralbaeva 2017; Jabeur 2017].

Effects on enzyme inhibition
A dry extract (methanol 50%) exhibited lipase inhibition of more than 70% in two assays and retained the effect in one of the assays after removal of tannins [Slanc 2009].

A dose-dependent inhibition of α-glucosidase and α-amylase was shown for a hot water extract (5 g drug/100 mL). α-Glucosidase was inhibited by 75% at 0.5 mg/mL and by 100% at 2.5 mg/mL. At a dose of 25 mg/mL α-amylase was inhibited by 71% [Ranilla 2010].

Inhibitory effects on α-amylase, α-glucosidase, acetyl-cholinesterase and butyrylcholinesterase were demonstrated for an extract (methanol 80% containing 1% HCl), with EC_{50} values of 8.2, 10.8, 73.8 and 199.9 mg/mL respectively [Nowicka 2019].

At 50 µg/mL, an extract (2 g drug/100 mL, 50% ethanol) reduced tyrosinase activity to 34% and elastase activity to 24% [Lianza 2020].

Antimicrobial activity
A methanolic dry extract (1:10) showed antimicrobial activity against *Bacillus subtilis, B. cereus, Klebsiella pneumoniae, Morganella morganii, Pseudomonas aeruginosa* and *Staphylococcus aureus* [Albayrak 2012].

Extracts (80% ethanol) from numerous samples of lime flowers were tested in a screening for antimicrobial activities. Among the panel of human and plant pathogenic microorganisms tested, *Streptococcus pyogenes* and *Bacillus subtilis* were the most sensitive bacteria to some of the samples, with MICs of 160 and 120 µg/mL respectively [Pavlović 2020].

Effect on cell proliferation
An aqueous dry extract (1.5 g/20 mL) had a significant ($p \leq 0.05$) stimulatory effect on the proliferation of lymphocytes with maximum activity at a concentration of 20 µg/mL. This effect was comparable with the benzodiazepine agonist Ro 5-4864 suggesting that the extract exerted the stimulatory action via peripheral type benzodiazepine binding sites [Anesini 1999].

Dry extracts of varying polarity (water, ethanol, dichloromethane) showed antiproliferative effects on the tumour lymphocyte cell line BW 5147. The dichloromethane extract was the most active with an EC_{50} value of 4.8 µg/mL (ethanol extract: 52.5 µg/mL, aqueous extract: 4987 µg/mL). On normal lymphocytes stimulated with concanavalin A, the dichloromethane extract exhibited the greatest antiproliferative activity with an EC_{50} value of 14 µg/mL (ethanol extract: 359 µg/mL, aqueous extract: 500 µg/mL) [Barreiro Arcos 2006].

Other effects
The interaction of an aqueous extract (3 g drug in 100 mL water, containing 0.84 mg caffeic acid, 0.11 mg rutin/mL and about 100 µM GABA) with the $GABA_A$ receptor complex in rat brain was investigated. The extract inhibited [^{3}H]muscimol binding with an IC_{50} value of 2.7 ± 0.3 µg/mL. Furthermore, it caused 44.0% inhibition of [^{3}H]flunitrazepam specific binding at the highest concentration tested (10 mg extract/mL) and stimulated ^{36}Cl uptake by the synaptoneurosomes [Cavadas 1997].

An ethanolic extract (100 g lime flower/L) from 5 to 1000 µg/mL caused a concentration-dependent and significant ($p \leq 0.05$) contractile effect on dispersed smooth muscle cells from guinea pig small intestine. The contraction was inhibited by atropine [Al-Essa 2007].

A dichloromethane extract at 10 µg/mL caused a moderate (50-75%) transactivation of the peroxisome proliferator-activated receptors α and γ. A detannified methanol extract at the same concentration moderately inhibited NF-κB [Vogl 2013].

A moderate bioadhesive effect of a polysaccharide fraction was demonstrated in the porcine buccal membrane model by the reduction of the carbohydrate titre in the supernatant of the incubation solution by approximately 40% [Schmidgall 2000].

Several procyanidins from lime flowers at concentrations of 1 and 5 µM had no effect on the viability of human neutrophils as compared to LPS-stimulated and -unstimu-lated controls. At these concentrations, most compounds significantly ($p<0.05$) reduced the IL-8 secretion of LPS-stimulated neutrophils, but did not influence TNF-α, MMP-9 and MIP-1α production [Czerwińska 2018].

Fractions enriched in alkaloids from a dry extract (water-acetone

7:3; yield 17%) significantly ($p<0.05$) increased acetylcholine-induced contractions of mouse trachea slices by approximately 30%, an effect which was reversed by atropine [Hake 2021].

In vivo experiments

Sedative effects
A hot water dry extract (not further specified), administered i.p. to male mice at 25, 50 and 100 mg/kg b.w., significantly ($p\leq0.01$) decreased mobility times and number of rearings in the open-field test. In the elevated plus maze test there was a significant ($p\leq0.01$) decrease in the total number of entries into the different sections of the maze [Coleta 2001].

Inhalation of an essential oil caused a 45% decrease in the motility of mice. The effect of the essential oil in caffeine-induced over-agitation of the animals was limited [Buchbauer 1992b].

Other effects
The hepatoprotective effect of an infusion was studied in Wistar rats for 50 days. The animals received either 20% ethanol or 20% ethanol plus 2% of an infusion with their drinking water. The ethanol-induced elevated serum levels of AST and LDH, as well as total albumin and total cholesterol, were reduced significantly ($p<0.05$) by the infusion and a trend towards a reduction was observed for ALT. With respect to markers of the antioxidant system such as reduced glutathione, glutathione reductase, SOD, GST, CAT, GPx and MDA in various organs (liver, spleen, kidney, brain, heart, erythrocytes) no restoration of ethanol-induced changes to control levels was seen [Yayalaci 2014].

Anthelmintic effects of a hydroacetonic extract enriched in tannins was tested against *Oesophagostomum dentatum*, a helminth parasite of pigs. Concentrations of 125 and 250 µg/mL strongly inhibited the development of eggs (stage L1) to the infective third stage larvae (L3), with complete suppression at 0.5 and 1 mg/mL. Overnight incubation with 1 mg/mL significantly ($p<0.01$) reduced the migratory ability of L3 larvae. Moulting of L3 to L4 larvae was decreased after 14 days of incubation (1 mg/mL; $p<0.01$), while reduced mobility of L4 larvae was noted after 24 hours [Williams 2014].

Pharmacokinetic properties
After inhalation of an essential oil, benzylalcohol and traces of benzaldehyde were detected in blood samples of mice [Buchbauer 1992b].

Preclinical safety data
A hot water extract (yield 9.2%) at a concentration of 640 µg/mL of the medium did not result in toxic effects on Vero cells in the MTT assay or in cell morphology [Sotiropoulou 2020].

Repeated dose toxicity studies
After supplementation of the drinking water of rats with 2% of an infusion for 50 days, no changes in serum ALT, total proteins, total albumin and total cholesterol were observed. Serum AST and LDH increased significantly ($p<0.05$) [Yayalaci 2014].

A hydroethanolic extract enriched in phenolics was added to the drinking water of K14HPV16 mice (wildtype HPV16- and haemozygotic HPV16+) at a concentration of 450 µg/mL for 33 days. No mortalities were observed. No significant differences in serum biochemical parameters (microhaematocrit, creatinine, urea, ALT, AST), in organ weights (heart, lung, spleen, left kidney and thymus), in oxidative stress parameters in the liver and kidneys (ROS, SOD, CAT, glutathione-S-transferase, MDA) as well as in liver and kidney lesions were observed between exposed groups and the respective controls receiving water. Only in male wildtype mice was an increase in CAT in the kidney significant ($p<0.05$) as compared to water control [Ferreira 2021].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)

iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

TORMENTILLAE RHIZOMA 2013

Tormentil

DEFINITION

Tormentil consists of the whole or cut, dried rhizome, freed from the roots, of *Potentilla erecta* (L.) Raeusch. (*P. tormentilla* Stokes). The dried drug contains minimum 7 per cent of tannins, expressed as pyrogallol ($C_6H_6O_3$; M_r 126.1).

The material complies with the European Pharmacopoeia [Tormentil].

CONSTITUENTS

Approximately 15 to 22% tannins consisting mostly of condensed tannins (changing to phlobaphenes during storage, "tormentil red"). Monomers such as catechin and epicatechin, dimers such as procyanidins B3 and B6, trimers as well as pentameric and hexameric derivatives [Hermann 1957, Ahn 1973, Glasl 1983, Lund 1985, Vennat 1992, Kolodziej 1992, Horz 1994; Scholz 1994, Frohne 2002].

Ellagitannins, mainly the dimer agrimoniin (1%) [Lund 1985], in addition to pedunculagin and 2,3-hexahydroxydiphenic acid glucoside as well as laevigatin B and F [Geiger 1990, Geiger 1991, Geiger 1994, Horz 1994, Frohne 2002].

p-Coumaric, sinapic and other phenolic acids such as caffeic and gallic acid as well as catechin gallates [Frohne 2002]. Flavonoids e.g. kaempferol [Vennat 1992, Horz 1994, Frohne 2002] and quercetin glucuronides [Kolodziej 1992].

Triterpene saponins such as chinovic, tormentic, euscaphic, ursolic, oleanoic and 3-epi-pomolic acids, as well as their glycosides e.g. the tormentic acid monoglucoside tormentoside and its isomers kaji-ichigoside F1 and arjunetin [Bilia 1994, Horz 1994, Stachurski 1995, Frohne 2002, Kite 2007].

CLINICAL PARTICULARS

Therapeutic indications

Non-specific, acute diarrhoea [Braun 1953, Hoffmann 1954, Horz 1994, Schulz 1999, Frohne 2002, Fintelmann 2002, Subbotina 2003, Schilcher 2007]. Adjuvant treatment of acute and subacute enteritis and colitis [Fintelmann 2002, Huber 2007, Moss 2007, Schilcher 2007].
Slight irritations of the mucosa of mouth and throat [Braun 1953, Hoffmann 1954, 1955, Horz 1994, Volodina 1997, Fintelmann 2002, Frohne 2002, Schilcher 2007].

Efficacy in these indications is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Internal use:

Adults:
Daily dose: 4-6 g herbal drug [Horz 1994, Frohne 2002, Schilcher 2007].
Decoction: 1 teaspoon per cup 3-4 times daily [Schilcher 2007].
Tincture (1:5): 30-50 drops 3-4 times daily [Van Hellemont 1988].
Tincture (1:10): 10-30 drops per small glass of water (ca. 50 ml) several times a day, in acute conditions every hour [Braun 1953, Schilcher 2007].
Dry extract (3.5–4.5:1; ethanol 60%): 1200 to 3000 mg daily [Huber 2007].

Children (from 3 months onwards):
Liquid extract (1:10, ethanol 40%): 3 drops daily per year of life [Subbotina 2003].

External use:
Decoction: 3-4 tablespoons per cup for gargling or rinsing several times daily [Schilcher 2007].
Tincture (1:5): Undiluted for brushing the gingiva several times daily [Van Hellemont 1988].
Tincture (1:10): 10-20 drops per glass of water for gargling or rinsing or undiluted for brushing the gingiva several times daily [Schilcher 2007].

Method of administration
For oral administration and local application.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contraindications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported, but due to the high content of tannins, in sensitive persons slight gastric complaints may occur [Schulz 1999, Schilcher 2007].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Astringent activity
Due to its high tannin content, tormentil has astringent effects [Horz 1994].

The astringency of ellagitannins isolated from tormentil was determined by haemanalysis with fresh human blood and by their relative affinity to methylene blue. Agrimoniin, pedunculagin and laevigatin F showed the highest activity [Geiger 1991, 1994].

Antisecretory activity
A lyophilized hot water extract (3 g herbal drug/150 ml) was examined on isolated rabbit colon. Mucosal application of 200-800 µg/ml of the extract showed a dose-dependent increase in the PGE_2-stimulated chloride secretion of 4-32% [Geiger 1994].

Antibacterial activity
A water-soluble fraction of tormentil was tested for its bacteriostatic activity on various cultures. At concentrations of 2.5-10 mg/ml, inhibition of *Staphylococcus aureus*, *Pseudomonas aeruginosa, Proteus vulgaris, Escherichia coli* (2 strains), *Shigella Boydii, Sh. Flexneri* type 1, *Sh. Sonnei* type 1, *Streptococcus faecalis* and *Pasteurella pseudotuberculosis* type 1 was observed. The same fraction showed agglutinating properties on suspensions of *Salmonella paratyphi* type A and B, *S. typhi, S. typhimurium, Brucella, Shigella Flexneri* type 1, *Sh. Sonnei* type 1 and *Pasteurella pseudotuberculosis* type 1 [Pourrat 1963].

Isolated polyphenolic compounds from tormentil showed bactericidal activity against *Bacillus subtilis, B. polymyxa* and *Azotobacter* [Nikitina 2007].

Antiviral activity
A decoction of tormentil was examined for its virustatic properties using HeLa cells incubated with a suspension of the respective virus. The decoction showed strong virustatic effects on *Herpes* virus [May 1978].

Antioxidant activity
The water-soluble fraction of a tormentil extract (prepared from 60 g powder, 500 ml ethanol 80% v/v), as well as procyanidins fractionated according to their degree of polymerisation, were tested for their antioxidant properties towards superoxide anion. The extract, an ethanolic fraction (containing monomers, dimers and trimers), a methanolic fraction (containing tetramers) and an acetone/water (7:3) fraction (containing pentamers and hexamers) showed superoxide anion-scavenging properties with an IC_{50} of 24, 56, 13 and 1.25 µg/ml, respectively [Vennat 1994].

The same preparations were tested for their effect on lipoperoxidation and anti-elastase activity. The extract, and the ethanolic, methanolic and acetone/water fractions, inhibited lipoperoxidation in rat liver microsomes induced by an Fe^{2+}/ADP complex and sodium ascorbate with an IC_{50} of 33, 6, 19 and 14 µg/ml, respectively. The extract inhibited elastase activity with an IC_{50} of 44 mg/ml and the methanolic and acetone/water fractions with an IC_{50} of 194 and 4 µg/ml, respectively, whereas the ethanolic fraction showed weak activity [Bos 1996].

In another experiment, the antioxidant effect of an extract (70% ethanol) was measured by its influence on photochemiluminescence of Gly-Trp using riboflavin for superoxide generation. A strong anti-oxidant effect was seen as compared to other plant extracts [Bol'shakova 1998].

Antioxidant effects of a tormentil preparation (single dose dissolved in the smallest possible volume of water, no further information available) were examined in cell-free oxidant-generating systems and inflamed human colorectal biopsies from patients with active ulcerative colitis who were treated with 5-aminosalicylate, prednisolone or azathioprine. In a xanthine/xanthine oxidase system which was used to detect superoxide scavenging by luminol-enhanced chemiluminescence, tormentil showed dose-dependent antioxidant activity (IC_{50} with a dilution of 10^{-6} parts per volume, ppv). In a phycoerythrin degradation assay which determined radical scavenging properties by fluorimetry, tormentil had an IC_{50} at a concentration of 10^{-5} ppv. In a chemiluminescence assay which was used to detect effects on the generation of oxygen radicals by sigmoid or rectal mucosal biopsies, tormentil significantly ($p < 0.05$) reduced chemiluminescence when biopsies were incubated with a 1:1000 dilution [Langmead 2002].

Anti-inflammatory activity
An extract (25 µg/ml, ethanol 50% V/V) of tormentil inhibited by 88 % the activity of porcine pancreatic elastase against the substrate N-succinyl-L-alanyl-L-alanine-L-valine-p-nitroanilide (SAAVNA) [Lamaison 1990].

An aqueous lyophilized extract of tormentil was tested for its

inhibitory activity on prostaglandin biosynthesis in bovine seminal vesicle microsomes with ^{14}C-arachidonic acid. Indomethacin was used as a reference. An inhibitory effect of 78 ± 9 % was shown. The same extract was tested for its platelet-activating factor (PAF)-induced exocytosis in neutrophils using SAAVNA (0.2 mM) as a substrate and produced an inhibition of 92 ± 2% [Tunon 1995].

Cytotoxic activity
An extract prepared with 40 % ethanol was tested on human lymphoblastoid Raji cells in the presence of 5 % fetal bovine serum. Methothrexate, fluorouracil, cyclophosphamide and vinblastine were used as reference substances. Tormentil suppressed the cell growth at 10 and 50 µg/ml. The final cell density was 30 ± 6 % and 2 ± 2 %, respectively, as compared to controls. In addition, tormentil was found to be cytotoxic and disrupted the process of cytokinesis which led to the formation of giant polyploid cells [Spiridonov 2005].

Agrimoniin showed strong cytotoxicity on MM2 cells in vitro (IC_{50}: 2.6µg/ml), but the activity decreased to about 4 % of the initial activity (62.5 µg/ml) after addition of foetal calf serum to the culture. I.p. injection of 10 mg/kg agrimoniin increased the number of peripheral white blood cells and the percentage of monocytes [Miyamoto 1987].

In vivo experiments

Antitumour effects
Isolated agrimoniin (from *Agrimonia pilosa*) administered i.p. before or after i.p. inoculation with MM2 mammary tumour cells effectively blocked tumour growth in C3H/He mice at doses higher than 10mg/kg. I.v. (3 mg/kg) and p.o. (300 mg/kg) application did not block the tumour growth but did cause cell regression, even 14 days before the tumour cell inoculation. Agrimoniin was also effective post-inoculation by each administration route and prolonged the life span. MH134-bearing and C3H/He mice were given agrimoniin i.p. once daily for 12 days or i.v. on days 7 and 10. In both cases tumour growth was suppressed but the animals died due to lymph node and lung metastasis. On Meth-A-bearing BALB/c mice, 3 and 10 mg/kg of agrimoniin markedly inhibited tumour growth after daily i.p. administration from day 10 to 18 [Miyamoto 1987].

Hypoglycaemic effects
The effect of isolated tormentic acid (from *Poterium ancistroides*) was studied in normoglycaemic, hyperglycaemic and streptozotocin-induced diabetic rats. Oral administration of 30 mg/kg of tormentic acid for up to 120 min, or intravenous application for up to 60 min, when compared to control produced a significant decrease in blood glucose levels ($p<0.05$ to 0.001 and $p<0.01$ to 0.001, respectively) with a corresponding significant increase in insulin levels ($p<0.01$ to 0.001 and $p<0.05$ to 0.01, respectively) when compared to control. In addition, tormentic acid at an oral dose of 30 mg/kg significantly improved glucose tolerance ($p<0.01$ to 0.001) and significantly increased the insulin secretory response to glucose ($p<0.05$ to 0.001) in glucose-induced hyperglycaemia (glucose load administration at 30, 60, 90, and 120 min). In rats with a severe state of streptozotocin-induced diabetes, neither oral administration of tormentic acid (30 mg/kg) nor glibenclamide (10 mg/kg) caused any significant decrease in plasma glucose concentration or any significant modification in plasma insulin levels [Ivorra 1988]

Other effects
A dried methanolic extract and a lyophilized aqueous extract (each prepared from 5g) were tested for their molluscicidal activity on *Biomphalaria glabrata*, the intermediate host of schistosomiasis. The snails were exposed to a distilled water solution containing the extract, tannic acid was used as control. The methanolic extract was 100% lethal from a concentration of 100 ppm onwards, the aqueous extract from 400 ppm, and tannic acid from 50 ppm [Schaufelberger 1983].

A tormentil extract (4:1; acetone 75 %) was tested for its antihypertensive, antiallergic, immunostimulating, interferon-inducing and antiviral effects in different *in vivo* models. Compared to chemical substances the tormentil extract did not demonstrate effects [Lund 1985].

Clinical data

Sixteen patients (15 completed the study) between 18 and 65 years suffering from active ulcerative colitis received a tormentil dry extract (3.5–4.5:1; ethanol 60%) at increasing doses of 1.2, 1.8, 2.4 and 3.0 g/d for 3 weeks each. Each treatment phase was followed by a 4-week washout phase. Aminosalicylate and steroid medication was permitted to be continued. For the assessment of efficacy, the outcome parameters were clinical activity index (CAI) and C-reactive protein. During therapy with 2.4 g extract per day, median CAI improved from 8 (6 to 10.75) mg/L at baseline to 4.5 (1.75 to 6); and median C-reactive protein from 8 (3 to 17.75) to 3 (3 to 6) mg/L. Mean CAI decreased during treatment phases whereas it increased during the washout phases. The therapeutic effects of tormentil extract could not be explained by concomitant medications and the use of steroids could be reduced [Huber 2007].

A randomized, double-blind, placebo-controlled trial was conducted in 40 children aged between 3 months and 7 years suffering from rotavirus diarrhoea. The treatment group (n=20) received 3 drops of tormentil extract (1:10, ethanol 40 %) per year of age, three times daily until discontinuation of diarrhoea, or a maximum of 5 days. A significant reduction of the stool output was seen on the second day (25.9 ml/kg vs. 31.5 ml/kg; $p=0.029$), and in total duration of diarrhoea (3 days vs. 5 days; $p<0.0001$) in the treatment group compared to the control group. After 48 h diarrhoea decreased in 8 (40 %; $p<0.0001$) children in the verum group compared to 1 child (5 %) in the placebo group. The volume of parenteral and oral rehydration was comparable in both groups on day 1. On day 2, patients in the treatment group required less parenteral rehydration solutions than patients in the control group (22.9 ml/kg vs. 46.6 ml/kg; $p=0.0009$). In addition, stool consistency in children in the treatment group was normalized within 4 days, compared to 6 days in the placebo group ($p<0.0001$). The length of hospitalisation was significantly shorter for the treatment group (3.5 days vs. 5.5 days; $p<0.0001$) [Subbotina 2003].

Pharmacokinetic properties

In the serum of 2 healthy volunteers who received a single dose of 2.0 g of an ethanolic dry extract of Tormentil (3.5–4.5:1; ethanol 60%) and 16 colitis patients who received 3.0 g daily, neither tannins nor their metabolites could be detected for a period of up to 8 or 6 hours, respectively [Huber 2007].

Preclinical safety data

Acute toxicity
No acute toxicity was observed in mice during the 72 hours after oral (300 mg/kg) and i.p. (200 mg/kg) administration of a tormentil extract (4:1; acetone 75 %) [Lund 1985].

Mice treated with a high dose of tormentic acid (600 mg/kg i.p.) did not show any visible signs of acute toxicity during 7 days of observation. Tormentic acid caused a slight sedation

in the animals after 30 and 90 min, with a small decrease in awareness and motor activity. No changes were observed in CNS excitation, posture, motor coordination and autonomic response [Ivorra 1988].

Intraperitoneal injection of more than 10 mg/kg agrimoniin to mice led to stretching and writhing reactions within 5 min. Average LD_{50} (male/female) was 101.4/102.7 mg/kg (i.p.), 31.2/35.4 mg/kg (i.v.) and > 1000 mg/kg (p.o.). After p.o. administration the animals developed only a slight depressed state for about 2 hours [Miyamoto 1987].

Clinical safety data

In a study in 16 patients with active ulcerative colitis who received a tormentil dry extract (3.5–4.5:1; ethanol 60 %) at increasing doses of 1.2, 1.8, 2.4 and 3.0 g/d for 3 weeks each, mild upper abdominal discomfort was experienced by 6 patients (38 %), but did not require discontinuation of the medication. The extract appeared safe up to 3.0 g/d [Huber 2007].

In a randomized, double-blind, placebo-controlled trial in 40 children aged between 3 months and 7 years suffering from rotavirus diarrhoea, no clinical side effects were detected in the treatment group (20 children) receiving tormentil extract (1:10, ethanol 40 %) [Subbotina 2003].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

UNCARIAE TOMENTOSAE CORTEX 2018

Cat's Claw Bark

DEFINITION

Cat's claw bark consists of the inner stem bark of *Uncaria tomentosa* (Willd. ex Roem. et Schult.) DC. It contains not less than 0.7 per cent of oxindole alkaloids expressed as uncarine E ($C_{21}H_{24}N_2O_4$, M_r 368.4) and calculated with reference to the dried drug.

A draft monograph for the European Pharmacopoeia has been published [Pharmeuropa 2012].

CONSTITUENTS

Characteristic constituents are oxindole alkaloids (0.15-2.6%), which are either pentacyclic (0.1-2.6%) or tetracyclic (0.0-1.0%) derivatives. Pentacyclic oxindole alkaloids consist of isopteropodine (uncarine E), pteropodine (uncarine C), isomitraphylline, mitraphylline, speciophylline (uncarine D) and uncarine F, while tetracyclic oxindole alkaloids are rhynchophylline, isorhynchophylline, corynoxeine and isocorynoxeine [Condori Peñaloza 2015; Bertol 2012; Pilarski 2010; Reis 2008; Kitajima 2002 and 2001; Ganzera 2001; Laus 1997].

Other constituents are indole alkaloids (akuammigine, tetrahydroalstonine, hirsutine, hirsuteine, dihydrocorynantheine), monoterpenoid glucoindole alkaloids (carboxystrictosidine derivatives), the β-carboline alkaloids such as harman [Hemingway 1974; Laus 1997; Kitajima 2002 and 2001], quinovic acid glycosides (0.05-0.8%) [Condori Peñaloza 2015; Cerri 1988, Aquino 1989, Pavei 2012], ursolic and oleanolic acid-type glycosides [Aquino 1990, Kitajima 2000, Kitajima 2004], sterols (campesterol, sigmasterol, sitosterol) [Senatore 1989], polyphenols and procyanidines (such as chlorogenic acid and further quinic acid esters, rutin, epicatechin and cinchonaines) (0.07-0.3%) [Navarro 2017; Condori Peñaloza 2015; Pavei 2010, Sheng 2005, Wirth 1997] and 7-deoxyloganic acid [Muhammed 2001].

CLINICAL PARTICULARS

Therapeutic indications
Adjuvant for the treatment of mild inflammatory conditions [The ABC Clinical guide to herbs]. Efficacy in this indication is plausible on the basis of literature and traditional use.

Posology and method of administration

Dosage
Adults: Decoction (20 g/l): daily dose 60 -100 ml [Jones 1995; The ABC Clinical guide to herbs 2003; Roth 2002].

Method of administration
For oral administration.

Duration of administration
No restriction.

Contra-indications
Should not be used by organ transplant patients [The ABC Clinical guide to herbs 2003].

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
It should be noted that a cat's claw extract has been shown to inhibit cytochrome P450 3A4 *in vitro* [Budzinski 2000, Foster 2003].

E/S/C/O/P MONOGRAPHS

A case study concerning the interaction between cat´s claw bark and protease inhibitors in an HIV-positive patient with cirrhosis associated with hepatitis C infection was reported. Serum trough concentrations (C_{min}) of atazanavir, ritonavir and saquinavir were conspicuously high (1.22, 6.13 and 3.4 µg/mL respectively) compared to recommended C_{min} values of 0.8, 0.25 and 2.1 µg/mL. Self-medication with cat´s claw bark was found to be the cause as the C_{min} levels normalized within 15 days after cat´s claw withdrawal [Galera 2008].

In a further case study, worsening of Parkinson's disease motor symptoms was reported after oral intake of cat´s claw bark. A 38 year old man was being treated with levodopa and pergolide and motor symptoms were well controlled. A few days after the first intake of a cat´s claw infusion, tremor and hypokinesia markedly increased. Following the withdrawal of cat´s claw bark intake after three weeks, he remained markedly hypokinetic for 1 more week. Motor symptoms then progressively improved to reach the basal state [Consentino 2008].

Cat´s claw bark (capsules containing 0.5% pentacyclic oxindole alkaloids) enhanced the action of diazepam (2 mg/kg) on spontaneous motor activity when administered orally at 3.5 and 7.14 mg/kg b.w. to mice. The sedative effects of diazepam were partially suppressed by the 7.14 mg/kg dose, whereas a stronger effect of diazepam on the exploratory ability and movement was observed when administered together with cat´s claw bark at 3.5 mg/kg ($p<0.001$). Muscle relaxant activity of the antidepressant drug was influenced to a small extent at both doses [Quilez 2012].

Ingestion of 1 mL of an aqueous cat´s claw bark extract (32 mg/mL) for 7 days affected the biodistribution of the radiobiocomplex sodium pertechnetate in rats (n=5) (3.7 MBq, 0.3 mL injected via the ocular plexus) compared to a control group (n=5) which received 0.9% NaCl solution. A significant ($p<0.05$) alteration in sodium pertechnetate uptake from 0.57 to 0.39% radioactivity (ATI)/g was observed in the heart, from 0.07 to 0.19% ATI/g in the pancreas and from 0.07 to 0.18%ATI/g in muscle. No significant differences were observed for the uptake in other organs such as brain, liver, duodenum, kidney, spleen, lung, stomach, blood, bone, thyroid and testis [Moreno 2007].

A single patient with systemic lupus erythematosus experienced acute renal failure associated with ingestion of 4 capsules of cat´s claw bark per day. Acute allergic interstitial nephritis was diagnosed, creatinine levels and proteinuria were increased compared to urine analysis before the intake and returned to normal upon discontinuation of intake. The patient had taken the cat's claw together with numerous oral medications including prednisone, atenolol, metolazone, furosemide and nifedipine [Hilepo 1997].

Pregnancy and lactation
No data available.

In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Anti-inflammatory activity
A decoction (20 g/L) significantly inhibited lipopolysaccharide-induced (1 µg/mL) production of macrophagal cytokine TNF-α (65-85% inhibition, $p<0.01$, IC_{50} 1.2 ng/mL) [Sandoval 2000].

In a further study, a similar extract (50 g/L) showed an IC_{50} value of 14.1 ng/ml in the same model. Alkaloid free HPLC-fractions (0.1 and 100 ng/mL) exhibited effects similar to the full extract (20-40% inhibition at 0.1 ng/mL, 65-80% at 100 ng/mL) and they also inhibited NO release [Sandoval 2002].

A decoction of cat´s claw bark (20 g/L, 0.56 - 0.70% pentacyclic oxindole alkaloids) stimulated IL-1 and IL-6 production by alveolar rat macrophages in a dose-dependent manner in the range from 0.025 - 0.1 mg/mL (IL-1: maximum 10 fold compared to control, IL-6: 7.5 fold). Enhanced IL-1 and IL-6 levels in lipopolysaccharide-stimulated macrophages (IL-1: maximum 5.2 fold compared to control, IL-6 > 2 fold) were also shown [Lemaire 1999].

A decoction at 100 µg/mL attenuated peroxynitrite-induced apoptosis in epithelial cells and macrophages ($p<0.05$), inhibited LPS-induced NO formation by 60% ($p<0.05$), iNOS gene expression and cell death, and markedly inhibited the activation of NF-κB [Sandoval 1998].

The same extract at 10 µg/mL significantly reduced PEG_2 production in murine macrophages after LPS (0.05 µg/mL) stimulation ($p<0.05$), whereas no effect was observed without the LPS stimulus [Piscoya 2001].

A purified aqueous extract (<0.05% alkaloids) reduced the 6-hydroxydopamine induced increase in iNOS expression, NF-κB and TNF-α in a human dopaminergic neuron neuroblastoma cell line ($p<0.05$) [Shi 2013].

An 80% ethanol extract (8:1; 5.61% penta- and tetracyclic oxindole alkaloids) impaired NF-κB DNA binding at a concentration of 500 µg/mL using Jurkat T cells and TNF-α as stimulus, whereas an aqueous extract (0.26% oxindole alkaloids) only slightly prevented NF-κB DNA binding at the same concentration. The extracts at 50 µg/mL inhibited COX-1 (7.8% and 32.7% respectively) and COX-2 (21.7% and 12.2% respectively) [Aguilar 2002].

Treatment of THP-1 monocyte like cells with an ethanolic extract inhibited the MAP kinase signalling pathway and altered cytokine expression. LPS-dependent expression of TNF-α was inhibited by 45-95% at 10-320 µg/mL ($p<0.05$). In contrast, IL-1β expression was augmented by 1.2-1.4 fold at 40-160 µg/mL, but was completely blocked at 320 µg/mL. Treatment of the cells with the extracts alone augmented IL-1β expression by 20 fold, but did not affect the expression of TNF-α In LPS stimulated cells treatment with the extract blocked ERK1/2 and MEK1/2 phosphorylation in a dose dependent manner, but did not influence the protein expression. Treatment with the extract inhibited LPS-dependent activation of specific NF-κB and activator protein family components. When NF-κB subunits nuclear localization signals were blocked, TNF-α production was diminished, whereas IL-1β expression remained unchanged [Allen-Hall 2007, 2010].

The procyanidine cinchonain 1b (42.5 µM/mL) inhibited

5-lipoxygenase by 100%, while (-)-epicatechin and cinchonain 1a were not active [Wirth 1997].

Quinic acid inhibited the NF-κB activity induced by activating Jurkat T cells with PMA and ionomycin, without effecting cell proliferation. The compound inhibited LPS-induced breakdown of IκBα. The antioxidant pyrolidine dithiocarbamate as positive control inhibited the breakdown and, in contrast to quinic acid, also affected the phosphorylation and resynthesis of IκBα [Akesson 2005].

Effects on immune functions
A dry extract (3% total alkaloids, no further details) stimulated macrophage phagocytosis up to 4.7 fold ($p<0.01$) at 0.13-1.3 mg/mL, whereas no effect was observed on the synthesis of IL-12 or IFN-γ or on the activity of natural killer cells. LPS and IL-12 in the presence of IL-2 were used as positive controls [Groom 2007].

Treatment of Dengue-virus infected human monocytes with a 50% ethanolic extract (2.9% alkaloids) or a non-alkaloidal fraction of the extract (0.1-100 µg/mL) did not impair the virus-induced increases in TNF-α, IFN-α, IL-10 and IL-6 production. However, the cytokine levels of TNF-α and IFN-α were significantly reduced by treatment with an alkaloid enriched fraction at 100 µg/mL ($p<0.05$); resulting cytokine levels were similar to those after dexamethasone treatment at 0.05 mM. IL-6 was not inhibited by the treatment. IL-10 was not significantly altered by cat´s claw bark, although a strong tendency for IL-10 inhibition was observed after treatment with the alkaloid fraction (572±219 pg/mL vs. 244±60 pg/mL after treatment) [Reis 2008].

A modified aqueous extract (alkaloids <0.01%, quinovic acid glycosides not detected, total phenol content 42%, arabinogalactan-protein content 24%) significantly increased NO (by 50% at 160 µg/mL, $p<0.05$), IL-6 (by 73% at 80 µg/mL, $p<0.05$) and TNF-α (by 230% at 80 µg/mL, $p<0.05$) production compared to the negative control whereas IL-1β levels were reduced (at 5-160 µg/mL, $p<0.05$) in mouse peritoneal macrophages [Lenzi 2013].

An alkaloid mixture (containing penta- and tetracyclic oxindole alkaloids, 0.9 g/100 g dried plant material) showed an enhanced effect on granulocyte phagocytosis in two in vitro tests (chemiluminescence assay, granulocyte test modified after Brandt), down to a concentration of 10^{-3} mg/mL. The most pronounced activity was found for isopteropodine (13-60%, 10^{-2}–10^{-6} mg/mL). Pteropodine, isomitraphylline and isorhynchophylline showed half of the activity, while rhynchophylline and mitraphylline were inactive [Wagner 1985a, Wagner 1985b].

Addition of pentacyclic oxindole alkaloids (1 µM, 7 days; 4% speciophylline, 6% uncarine F, 2% mitraphylline, 3% isomitraphylline, 28% pteropodine and 57% isopteropodine) to supernatants of human endothelial cells (EA.hy926) induced the proliferation of resting or low activated human B and T lymphocytes. Proliferation of normal human T- and B-lymphoblasts as well as of Raji and Jurkat lymphoblastoid cell lines was inhibited (viability not impaired) and the myeloid cell line U-937 was not affected. No effect on proliferation was found when alkaloids alone, or together with a supernatant of untreated endothelial cells, were added to the lymphocytes. Thus, proliferation was not influenced directly by the alkaloids. No activity was found for tetracyclic derivatives (67% rhynchophylline and 33% isorhynchophylline) on proliferation itself, but there was a dose-dependent inhibitory effect of pentacyclic oxindoles on Raji and Jurkat cells [Wurm 1998].

Oxindole alkaloid mixtures (50-500 µg/mL) dose dependently decreased neopterin formation and tryptophan degradation induced by IFN-γ in stimulated or non-stimulated human peripheral blood mononuclear cells; pentacyclic derivatives ($p<0.01$ at 150-500 µg/mL) were less active than tetracyclic ones ($p<0.01$ at 50-500 µg/mL) [Winkler 2004].

Antioxidant activity
Inhibition of lipid peroxidation in rat liver homogenates was determined with methanolic extracts of cat's claw root and stem bark (dichloromethane pre-extracted; root: IC_{50} 259 µg/mL, stem bark: IC_{50} 56 µg/mL, catechin as control: IC_{50} 1.0 µg/mL). Aqueous extracts of roots were inactive and aqueous extracts of stem bark were only active in high doses (100 and 1000 µg/mL). Methanolic extracts also inhibited a free radical-mediated damage of the sugar moieties of DNA (root IC_{50} 82 µg/mL; stem bark IC_{50} 16 µg/mL; catechin: IC_{50} 5.0 µg/mL) [Desmarchelier 1997].

In another assay, a decoction (50 g/L; 0.9% oxindole alkaloids, 2.4% flavonols) showed inhibition of lipid peroxidation in mouse brain homogenates (IC_{50} 148 µg/mL). Inhibition of DPPH and ABTS radical production was observed in a concentration dependent way (DPPH: IC_{50} 21 µg/mL, ABTS: IC_{50} 7.7 µg/mL). The extract also provided protection of deoxyribose against hydroxyl radicals in a dose-dependent manner [Sandoval 2002].

A similarly prepared decoction (20 g/L) at a dose of 10 µg/mL prevented the loss in cell viability (RAW 264.7) induced by 0.3 µM DPPH ($p<0.01$) [Sandoval 2000].

A purified aqueous extract (<0.05% alkaloids, 8-10% carboxyalkylesters) scavenged DPPH and ABTS radicals in a dose-dependent manner (IC_{50} 32.2 µg/mL and 20.1 µg/mL respectively). At 25 µg/mL, hydroxyl anions were scavenged by 55.7%, superoxide anions by 21.0% and singlet oxygen radicals by 14.2%. Quinic acid as constituent was inactive at 25 µg/mL, and the scavenging rate on hydroxyl radicals was only about 15% at 5 mg/mL. The extract also inhibited 6-hydroxydopamine induced increase of reactive oxygen species (ROS), reduction of mitochondrial membrane potential, loss of cell viability as well as increase in lipid peroxidation (by 28.9%) in a human dopaminergic neuron neuroblastoma cell line ($p<0.01$) [Shi 2013].

Pteropodine scavenged DPPH radicals by 98% at 250 µg/mL [Paniagua-Perez 2009].

Antiviral activity
Treatment of Dengue-virus infected human monocytes with a 50% ethanolic extract (2.9% alkaloids) at 10 mg/mL significantly decreased viral antigen detection ($p<0.05$), an alkaloid fraction showed an effective inhibitory activity at 1 µg/mL ($p<0.05$), whereas an alkaloid-free fraction was inactive. Cell rates were similar to those after dexamethasone treatment at 0.05 mM [Reis 2008].

Six quinovic acid glycosides were tested for their antiviral activity against two RNA viruses. All compounds inhibited vesicular stomatitis virus infections in a chicken embryo related (CER) cell line at dose levels close to cytotoxic doses (MIC_{50} 20-71 µg/mL, LD_{50} 80-150 µg/mL). Five of the tested compounds were inactive against rhinovirus 1B infections in HeLA cells, only one reduced the cytopathogenic effect by 50% at a dose of 30 µg/mL (maximal non-toxic concentration for HeLA cells: 60 µg/mL) [Aquino 1989].

A concentrated, freeze-dried 40% hydroethanolic extract (183.8 µg/mg total polyphenols, 15.4 µg/mg alkaloids and 67.8 µg/mg

quinovic acid glycosides) inhibited HSV-1 replication in Vero cells, when added to cells simultaneously (IC_{50}<15.75 µg/mL) but not after virus infection. No virucidal effect was observed when virus suspensions were pre-incubated with the extract. The extract did not prevent penetration of HSV into cells but showed a strong inhibition of its attachment. An alkaloid (62.7 µg/mg) and a quinovic acid glycoside (217.8 µg/mg) fraction were inactive [Caon 2014].

Antiproliferative and cytotoxic effects
An aqueous extract dose-dependently reduced [^{3}H]-oestradiol-specific receptor binding in cytosol from oestrogen-dependent tumours (ductal carcinoma). Pre-treatment of the cytosol with cat's claw bark or tamoxifen as control (20 µg each) reduced specific binding by 47.2% and 69.3% respectively [Salazar 1998].

Extracts of cat's claw stem bark were tested for their inhibitory effects on proliferation in a human breast cell line (MCF7). The methanolic extract (33:1) was more effective than an aqueous extract (50:1) (IC_{50}-values 38 and 270 µg/ml respectively). At the maximum concentration (1 mg/mL) both extracts were toxic [Riva 2001].

In another study, a purified aqueous extract (< 0.05% alkaloids, 8-10% carboxy alkyl esters) inhibited proliferation of human leukaemic cells (HL60) and lymphoma cells (Raji), with IC_{50}-values of 71 µg/mL and 84 µg/mL respectively. Reduced inhibitory activity was seen in the leukaemic cell lines K562 (IC_{50} 200 µg/mL) [Sheng 1998, Akesson 2003a].

The antitumor activity of the same extract was also demonstrated in the clonogenic assay, a dose-dependent response being observed on the colony survival (IC_{50} 83 µg/mL, HL60). In the MTT assay, IC_{50} values of 100 µg/mL (HL60) and 267 µg/mL (K562) were calculated. The suppressive effect on tumour cell growth appeared to be mediated via induction of apoptosis, as demonstrated by characteristic morphological changes, internucleosomal DNA fragmentation after agarose gel-electrophoresis and DNA fragmentation quantification. The extract induced a dose-dependent and delayed type of apoptosis (48 hours after exposure), whereas no significant increase of necrosis was observed [Sheng 1998].

The extract also inhibited proliferation of normal mitogen-activated mouse B- and T-lymphocytes; the effect was not caused by toxicity or induction of apoptosis. Furthermore, no interference with IL-2 production or receptor signalling was observed [Akesson 2003a].

An ethanolic extract (14:1) dose dependently inhibited TPA induced Epstein-Barr virus early antigen activation in Raji cells [Kapadia 2002].

Of various tested cat´s claw bark extracts, an ethanolic extract (1 g/10 mL, 37°C, 3.5% pentacyclic oxindole alkaloids) was shown to be the most active one against Lewis lung carcinoma (IC_{50} = 25.06µg/ml), cervical carcinoma (IC_{50} = 35.69µg/ml) and colon adenocarcinoma (IC_{50} = 49.06µg/ml), whereas an alkaloid enriched fraction (51.7% pentacyclic oxindole alkaloids) was especially effective in inhibiting proliferation of cervical carcinoma (IC_{50} = 23.57µg/ml), breast carcinoma (IC_{50} = 29.86µg/ml) and lung carcinoma cell lines (IC_{50} = 40.03µg/ml). An aqueous dry extract (1 g/10 mL, 37°C, 0.43% pentacyclic oxindole alkaloids) showed the lowest activity against all cell lines [Pilarski 2010].

The aqueous extract as well as the alkaloid rich fraction were also studied for their effects on the Wnt-signaling pathway, a central regulator of development and tissue homeostasis. The alkaloid rich fraction inhibited the Wnt-signaling activity in a human cervical carcinoma cell line (HeLa, IC_{50} = 38 µg/mL), and in the human colorectal cancer cell lines HCT116 (IC_{50}=60 µg/mL) and SW480 (IC_{50}=29 µg/mL). The aqueous extract was less active (IC_{50}= 278 µg/mL, 150 µg/mL and 190 µg/mL respectively). Considering the ratio of a Tcf-reporter construct (TOP-luciferase) and a mutated reporter construct (FOP-luciferase), it was evident that the effects were only specific in HeLa and HCT116 cells at concentrations of >300 µg/mL, whereas the alkaloid-rich fraction displayed an inhibitory effect at much lower concentrations. No effect was observed on beta-Catenin levels, but expression of endogenous Wnt target gene cMyc was reduced by both extracts. Wnt-inhibition IC_{50} values were much lower than 50% growth inhibition; it is suggested that the decrease in Wnt-signaling is not caused by reduced cell proliferation. The alkaloid rich fraction was clearly less toxic to non-cancer cells and to cells without activated Wnt-signaling than to cancer cells with aberrantly activated Wnt-signaling activity [Gurrola-Diaz 2011].

Hexane, ethyl acetate, butanol and methanol cat´s claw bark extracts inhibited viability of the human promyelotic leukemic cell line HL-60 by 50% at 13.0 µg/mL, 18.0 µg/mL, 13.5 µg/mL and 50.3 µg/mL respectively. The ethyl acetate extract was further investigated; at 100 µg/mL it clearly induced morphological changes and chromosomal condensation in HL-60 cells. The observed apoptotic effect was dose dependent with 74.7% apoptotic cells at 100 µg/mL. Cells treated with the extract underwent rapid loss of mitochondrial transmembrane potential, stimulation of phosphatidylserine flip-flop, release of mitochondrial cytochrome c into cytosol, induction of caspase-3 and -9 activity and induced cleavage of DNA fragmentation factors. Apoptosis was accompanied by up-regulation of Bax, down-regulation of Bcl-XL and cleavage of Mcl-1 [Cheng 2007].

Pentacyclic oxindole alkaloids, with the exception of mitraphylline, inhibited proliferation of acute lymphoblastic leukaemia T cells in a dose-dependent manner (MTT-assay and clonogenic assay). The effect of the most potent alkaloids uncarine F and pteropodine correlated with the induction of apoptosis. After 48 h, the two alkaloids increased apoptotic cells by 57% at 100 µmol/L ($p<0.01$). Apoptosis of alkaloid treated cells was not impaired by Bcl-2 overexpression, and no activation of caspase-9 was observed. The same dose did not increase apoptosis in G0/1-arrested cells; however, at 200 µmol/L the effect was comparable to a dose of 100 µmol/L in dividing cells [Bacher 2005].

In another study, mitraphylline had a stronger antiproliferative effect on a glioma (IC_{50}=20 µM) and a neuroblastoma cell line (IC_{50}=12.3 µM) than cyclophosphamide (IC_{50}=50.85 µM and 8.05 µM respectively) or vincristine (IC_{50}=30.43 µM and 10.05 µM respectively) as positive controls [Garcia Prado 2007].

The alkaloid also inhibited the proliferation of Ewing´s sarcoma and a breast cancer cell line by 50% at 17.15 and 11.80 µM respectively, cyclophosphamide at 67.60 µM and 38.01 µM, and vincristine at 39.16 µM and 44.66 µM respectively [Garcia Gimenez 2010].

Isopteropodine and pteropodine at 100 µM inhibited proliferation in human medullary thyroid carcinoma and breast carcinoma cells by 57.1%, in a phaeochromocytoma cell line by 36% and in a melanoma cell line by 13%. A methanolic extract at 100-200 µM did not show activity. In the medullary thyroid carcinoma cells a decrease in mitochondrial dehydrogenase activity and an increase in caspase-3 and -7 as well as in poly(ADP-ribose) polymerase fraction was observed, whereas bcl-2 overexpression remained constant [Rinner 2009].

Cytotoxicity of (iso)pteropodine, (iso)mitraphylline, uncarine D, rhynchophylline, 7-deoxyloganic acid, as well as β-sitosteryl glucoside was tested in several human cancer cell lines using doxorubicin (DOX) as control. Uncarine D showed weak cytotoxic activity against malignant melanoma (IC_{50} = 30 µg/mL; DOX < 1.1), epidermoid carcinoma (IC_{50} = 35 µg/ml; DOX 1.7), ductal carcinoma (IC_{50} = 34 µg/mL; DOX 1.7) and ovarian carcinoma (IC_{50} = 34 µg/mL; DOX 2.0), whereas pteropodine was only cytotoxic in ovarian carcinoma (IC_{50} = 37 µg/mL), and the other compounds were inactive [Muhammad 2001].

Isopteropodine and pteropodine showed moderate cytotoxicity against several mammalian cell lines with IC_{50} values from 17 to 51 µg/mL. Both compounds exhibited weak DNA-damaging activity against the yeast strains RS321 and RS322, which lack one of the three known DNA repair pathways. No effect was detected against the corresponding wild-type strain [Lee 1999].

A quinovic acid glycoside enriched fraction decreased the growth and viability of bladder cancer cell lines T24 (IC_{50} 78.4 µg/mL after 72h) and RT4 (IC_{50} 99.4 µg/mL after 72h). In T24 cells the fraction induced apoptosis by activating caspase-3 and NF-κB, but it did not induce cell cycle arrest or alter phosphorylated and total protein levels of PTEN and ERK [Dietrich 2014].

Antimutagenic activity
Sequentially prepared extracts of cat's claw bark (light petroleum, chloroform, chloroform-methanol 9:1, methanol and water) and some chromatographic fractions of the chloroform-methanol extract exerted a protective action against photomutagenesis induced by 8-methoxy-psoralen plus UVA (15 min of irradiation) in *S. typhimurium* TA 102 at a dose of 100 µg/mL. The methanolic extract showed the most pronounced activity (59%). β-Carotene was used as a positive control (68%, same dose) [Rizzi 2003].

Skin protective activity
Incubation of organogenic human skin cultures for 24 h with a purified aqueous extract (5 mg/mL) after exposure to 100 mJ/cm^2 of UVB reduced the number of UV-induced necrotic cells by 95% ($p<0.001$). When cells were incubated for 6 h with the same dose and then irradiated by UVB (0-100 mJ/cm^2), no effect was observed on the level of thymine dimers as UVB induced DNA damage. However, after re-treatment with the extract for 24 h, a reduction of thymine dimer producing cells of 26% was observed at 75 mJ/cm^2 and 63% at 100 mJ/cm^2 compared to the cells before the 24 h incubation period ($p<0.001$) [Mammone 2006].

Influence on cytochrome P450
A non-specified extract of cat's claw was found to be an *in vitro* inhibitor of human cytochrome P450 3A4 (IC_{50} at concentrations of less than 1% of the extract; fluorometric microtiter plate assay) [Budzinski 2000].

In a further study, a methanolic extract (0.13% pentacyclic oxindole alkaloids; aliquot of 25 mg/mL) inhibited the activities of cytochrome P450 2C9, 2C19, 2D6 and 3A4 (11.4, 5.2, 13.4 and 56.8% inhibition respectively). Determination of the interaction on marker substrates by the extract and the protease inhibitor nelfanavir showed an additive effect of the two drugs with only little evidence of synergism [Foster 2003].

Effect on muscarinic and 5-HT2 receptors
The effects of isopteropodine and pteropodine on the function of Ca^{2+}-activated Cl^- currents evoked by stimulation of G protein-coupled muscarinic M_1 acetylcholine and 5-HT_2 receptors in Xenopus oocytes injected with rat cortex total RNA were studied. The alkaloids at 1-30 µM failed to induce membrane current, but markedly enhanced current responses evoked by acetylcholine and serotonin. Both compounds produced 2.7-3.3 fold increases in the acetylcholine response with EC_{50} values of 9.52 and 9.92 µM and 2.4-2.5-fold increases in the serotonin response with EC_{50} values of 13.5 and 14.5 µM respectively. Mitraphylline failed to modulate current responses. No effects were observed on currents mediated by glutamate receptors or N-methyl-D-aspartate, kainic acid or glycine [Kang 2002].

Effect on human erythrocytes
Incubation of a human erythrocyte suspension with an ethanolic dry extract (8:1, 20% polyphenols, 34.8 mg alkaloids per g extract) at 100-500 µg/mL, and incubation with an aqueous dry extract (9:1, 10% polyphenols, 4.3 mg alkaloids per g extract) at 250-500 µg/mL, resulted in a slight, but statistically significant ($p<0.001$) decrease in haemoglobin outflow. Haemolysis, formation of met-Hb at 5-500 µg/mL or haemoglobin denaturation at 250 µg/mL were not observed for either extract within 24 h of incubation. The extracts at 250 µg/mL did not cause a statistically significant increase in ROS levels or in lipid peroxidation after 1 h of incubation. Both extracts dose dependently depleted the extent of 2,4-dichlorophenol (250 µg/mL) provoked haemoglobin oxidation and lipid peroxidation, and decreased the level of ROS and haemolysis. The effects were statistically significant ($p<0.001$) at 100 µg/mL for the ethanolic and at 250 µg/mL for the aqueous extract. No protective effect was observed against catechol-induced (100 µg/mL) haemolysis or oxidation [Bors 2011].

Incubation of erythrocytes for 1 h and 5 h with the same extracts at 250 µg/mL resulted in reduced changes in catalase activity induced by 2,4-dichlorophenoxyacetic acid and 2,4-dichlorophenol ($p<0.001$). Changes induced by catechol were significantly reduced after 1h of incubation ($p<0.001$), but not after 5h. An effect on catalase activity was not observed without the inducing agents [Bukowska 2012].

Slight disturbances in size and shape of erythrocytes were observed by flow cytometry and phase contrast microscopy after incubation with 100 µg/mL ethanolic extract and with 250 µg/mL aqueous extract ($p<0.001$). At 250 µg/mL, externalization of phosphatidylserine on the erythrocyte surfaces was noticed [Bors 2012].

In vivo studies

Effects on immune functions
Enhancement of phagocytosis in mice, determined by carbon-clearance test (after Biozzi), was more pronounced after i.p. administration of an alkaloid-rich aqueous macerate (10 mg/kg b.w., 24 h before the test; 2.3 fold compared to control) than after administration of an alkaloid-free macerate (1.7 fold compared to control). The alkaloid mixture itself showed significant activity only after adding a tannin mixture (2.2 fold compared to control) [Wagner 1985b].

A small but significant ($p<0.05$) elevation in the white blood cell count of rats was found after treatment with a purified aqueous extract (40 and 80 mg/kg b.w. daily for 8 weeks or 160 mg/kg b.w. for 4 weeks by gavage) when compared to controls [Sheng 2000a].

In a further study, the effect of the same extract on doxorubicin-induced leucopoenia was evaluated in rats (2 mg/kg b.w., i.p. 3 times at 24 h intervals). After the last treatment the animals were daily gavaged with the extract for 16 consecutive days (40 and 80 mg/kg b.w.). As a positive control, a granulocyte colony stimulator was administered (s.c., 5 and 10 µg/kg b.w. for 10 days). The white blood cells recovered significantly ($p<0.05$) faster in treated than untreated groups (cat's claw group:

recovery in 4 days at a dose of 80 mg/kg and in 9 days at 40 mg/kg; granulocyte colony stimulator: within 24 h). However, the recovery by cat's claw bark was a more natural process, with all fractions of white blood cells being increased proportionally, whereas the control mainly elevated the neutrophil cells. These results were confirmed by microscopic examination of the blood smears [Sheng 2000b]. A comparable effect was observed when a quinic acid ester enriched fraction was administered at 200 mg/kg [Sheng 2005].

A dose-dependent increase in spleen cell numbers was observed when a purified aqueous extract was supplied to mice in drinking water at daily doses of approximately 125, 250 or 500 mg/kg b.w.. This increase reached a plateau within 3 weeks. In contrast to the total number of spleen cells, the proportions of B cells, T cells, NK cells, granulocytes and memory lymphocytes remained unchanged compared to control after 63 days. The total number of thymocytes and body or spleen weight were not influenced by the treatment. The effect on spleen cells was reversible as cell density returned to normal levels within four weeks after interruption of application. Furthermore, no significant effects on precursor cell maturation or on the output rate of mature T cells from thymus were observed. The extract significantly ($p<0.05$) prolonged lymphocyte survival in lymphoid tissues without increasing the proliferation rate [Akesson 2003b].

In a consecutive study, the effect of the same extract (500 mg/kg b.w.) was compared to that of quinic acid, a component of the extract (125, 250 or 500 mg/kg b.w.). In both groups the number of spleen cells increased significantly within 21 days ($p<0.02$). In the extract-treated group no increase in white blood cells, blood lymphocytes or erythrocytes was observed. In contrast, mice treated with increasing concentrations of quinic acid had increasing numbers of white blood cells and lymphocytes ($p<0.002$). However, the body weight of those animals (n=10) was significantly reduced ($p<0.01$) [Akesson 2005].

Treatment of rats with a purified hot water extract (daily dose of 40 and 80 mg/kg b.w. for 8 weeks) dose-dependently enhanced PHA stimulated lymphocyte proliferation in splenocytes ($p<0.05$ and $p<0.01$ respectively) [Sheng 2000a].

Treatment of BALB/c male mice once a day with 125, 500 or 1250 mg/kg b.w. of a 50% hydroalcoholic extract (2.9% oxindole alkaloids) for 28 days (no further treatment) resulted in a significant increase in the relative number of lymphocytes ($p<0.05$) associated with a decrease in granulocytes ($p<0.01$). The increase of mature CD^{4+} T-lymphocytes was more pronounced in the groups treated with 125 or 500 mg/kg (27.8% and 32.3% respectively, compared to 21.3% in the control group; $p<0.05$). Whereas a reduced percentage of CD^{4+} T-lymphocytes and a higher percentage of $CD45RA^{+}$ B-lymphocytes was observed in the group treated with the highest dose (80% compared to 51.7% in the group treated with 500 mg/kg b.w. and 63.5% in the control group). This increase in B-lymphocytes was associated with an enlargement of the splenic marginal zone (relative organ weight 0.37 vs 0.30 in the control, $p<0.05$) and an increase in the cellularity of thymic medulla [Domingues 2011a].

The same extract was tested in experimental immune-mediated diabetes in mice. Diabetes was induced by five i.p. injections of streptozotocin (MLDS) at 5 mg/kg b.w. on 5 consecutive days. Treatment of mice (7 groups, n=8) with the extract by gavage at 10-400 mg/kg b.w. for 21 days resulted in a significant reduction of diabetes incidence and glycaemic levels ($p<0.05$), the highest dose completely abrogated diabetes incidence at day 12 ($p<0.001$). The morphometric analysis of insulitis revealed a clear protective effect, animals treated with the extract at 400 mg/kg b.w. presented a higher number of intact islets ($p<0.001$), a significant inhibition of destructive insulitis ($p<0.05$), and protection against the loss of insulin-secreting β-cells. Application of MLDS resulted in a reduced number of CD^{4+} cells which was normalized by the treatment at 100 or 400 mg/kg b.w. ($p<0.05$), CD^{8+}cell counts were not significantly influenced. Furthermore, the treatment resulted in a TH2 cytokine polarization with a significant increase in IL-4 production and in $FoxP3^{+}$ trag regulatory T-cells [Domingues 2011b].

In another study, mice receiving filgrastim at 3 and 9 µg i.p. and oral doses of 5 and 15 mg of a 70% hydroalcoholic extract for four days (n=6 per group) showed significant recovery ($p<0.005$) of the neutrophil counts compared to the control after ifosfamide-induced neutropenia. The effect of the cat´s claw bark treatment was calculated as 85.2 % compared to that of filgrastim as a positive control. No differences were observed in levels of non-protein thiols or in the activities of antioxidant enzyme catalases or superoxide dismutase among all groups [Farias 2011].

Cat´s claw protected mice against a lethal dose of *Listeria monocytogenes*. Mice were treated orally with an extract (1% alkaloids, dissolved in water, no further details) at 10-200 mg/kg b.w. for 7 consecutive days. The animals were infected with a lethal dose of *L. monocytogenes* 3 h after the end of treatment and observed for 30 days. All untreated mice died within 5 days, whereas 15% of animals treated with the extract at 50 mg/kg and 35% of animals treated at ≥100 mg/kg survived the infection. The treatment also prevented the myelosuppression and splenomegaly caused by sublethal infections due to significantly increased numbers of granulocyte-macrophage progenitors in the bone marrow ($p<0.001$). A dose of 100 mg/kg stimulated progenitor production within 24 h, and the effect was sustained for up to 3 days at least. In contrast, the increase of progenitors in the spleen observed at 48 and 72 h after infection was fully reversed ($p<0.001$); in non-infected mice no effect on spleen progenitors was observed. The same dose also upregulated the production of IL-1, IL-6 and colony-stimulating factors. No significant changes were observed in white blood cell counts. A significant increase of neutrophils ($p<0.05$) and reduction of lymphocytes and monocytes ($p<0.01$) were observed at 48 h and 72 h after bacterial challenge [Eberlin 2005].

A hydroalcoholic dry extract (10% yield) was found to be immunostimulatory in a study involving mice infected with formalin-inactivated whole *Sendai* virus (500 µg measured as total protein in 200 µL phosphate-buffer saline pH 7.2). One group (A) was treated intragastrically with the virus suspension alone (n=6), another (B) with virus and 0.56 mg extract (n=6), a third group (C) with the virus and 5.6 mg extract (n=6) seven times on alternate days. A fourth group (D, n=6) was immunized with the virus (5 µg s.c.) twice, at day 0 and 12. The saliva IgA antibody response was significantly higher in group C than in groups A, B and D at days 2, 7 and 14 after the last immunization, IgA titres were significantly increased between days 2 and 14 only in group C ($p<0.05$). Significant differences were also observed in serum IgG titres in groups B-D at day 7 with a maximum response and a significant decrease between day 7 and 14 after the last immunization. The response of group A remained reduced; the highest response was observed for group D. The serum haemagglutinin antibody response was increased in groups B, C and D within 2 to 14 days after the last immunization ($p<0.05$), being most pronounced in group D [Bizanov 2005].

In a study assessing lymphocyte production in 6 groups of mice (n=5 each), four of the groups received pteropodine (100-600 mg/kg b.w. i.p.), one group received distilled water (0.4 ml) as control and the final group received α-interferon (0.01 µL/kg

b.w.). Lymphocyte production was significantly induced after 24 h from 44.5% in the control group to 58.5-68.4% in the pteropodine groups ($p<0.05$) and compared to 50.3% after α-interferon administration. After 96 h lymphocyte counts in the control group were 47.4%, and significantly ($p<0.05$) higher in the pteropodine groups 56.0-78.8%, and the α-interferon group (56.0%) [Paniagua-Perez 2009].

Antiinflammatory activity
An ethanolic extract (80%, 8:1; 5.61% penta- and tetracyclic oxindole alkaloids) reduced mouse paw oedema at a concentration of 50 mg/kg b.w., equivalent to 7 mg/kg b.w. indomethacin (application via gastric probe). The same effect was observed for 200 mg/kg b.w. of an aqueous extract (0.26% oxindole alkaloids) [Aguilar 2002].

A decoction (20 g/L, diluted 1:4, provided in the drinking water ad libidum) markedly attenuated indomethacin-induced enteritis in mice. Significant reduction of myeloperoxidase activity ($p<0.05$), morphological damage and liver metallothionein protein concentration was shown (control: 30.5 µg/g tissue, indomethacin treated animals: 216.6 µg/g tissue, indomethacin and cat's claw bark: 69.6 µg/g tissue) [Sandoval 1998].

In a further study, a protective effect of an aqueous extract against indomethacin-induced gastritis in rats was observed. Micropulverized drug (5 mg/mL) was given as a decoction in the drinking water for 3 days prior to oral administration of 20 mg/kg b.w. indomethacin. The degree of mucosal injury, apoptosis in stomach epithelial cells and TNFα mRNA induction in the mucosa was significantly reduced ($p<0.01$) [Sandoval 2002].

The effect of a decoction (20g/L) on ozone-induced lung inflammation in mice was evaluated by assessing total protein levels of bronchoalveolar lavage fluid (BALF), cytology, lung histopathology and morphometry. To characterize ozone-induced acute pneumonitis, 40 mice were randomly assigned to 4 groups. One group was exposed to room air only, the other three groups were exposed to 2 ppm ozone for 4 h and killed 0, 4 and 8 h after the exposure. Total protein in BALF increased with increased time after the exposure, after 8 h total protein was significantly higher ($p<0.05$) than in the control group or in mice killed immediately after the exposure. Ozone inhalation was also characterized by a high number of infiltrating neutrophils within the bronchiole´s lumen and wall immediately after exposure; no neutrophils in cytology smears were found in the control group. Histologically, the bronchiolar epithelium showed necrosis and sloughing of bronchiolar epithelial cells with minimal oedema. Oral administration of the decoction in the drinking water (50 or 100%) for an 8 day period to 24 mice did not influence the total protein level in BALF if the animals were killed immediately after the exposure compared to a control group (n=12). In the treated groups sacrificed after 8h the protein levels were markedly decreased (in the 100% treatment group by 50% compared to control, $p< 0.05$). Furthermore, a lower degree of necrosis, a higher number of intact epithelial cell nuclei in bronchial wall and a decreased number of infiltrating neutrophils were observed [Cisneros 2005].

In another study, the effect of a decoction (20g/L) on LPS-induced acute lung injury in mice was evaluated by assessing inflammatory cell concentration of bronchoalveolar lavage fluid (BALF) and histology. Intranasal instillation of LPS (100 µg/kg b.w.) induced a significant increase in polymorph nuclear neutrophils and macrophages in BALF, which was reduced to basal values in animals (n=8) treated with a single dose of dexamethasone (2.5 mg/kg b.w.) or in mice pre-treated with cat´s claw bark decoction for 7 (n=8) or 90 (n=8) days (administered in water ad libitum) ($p<0.05$) but not in animals pre-treated for 15 or 30 days. No significant changes were observed without LPS instillation. Both cat´s claw and dexamethasone treatments reduced LPS-induced lung oedema, exudation and lung injury histology. Toxic effects were not observed in any of the cat´s claw treated groups; water and food consumption, body and organ weight, kidney, liver and lung pathology were not affected [Roque 2009].

In another study, root bark extracts were tested (petroleum ether, chloroform, chloroform-methanol 9:1, methanol and water) in rats (p.o.). Only the chloroform-methanol extract (50 mg/kg b.w.) and the aqueous extract (84 mg/kg b.w.) reduced carrageen-induced paw oedema, by 69.2 and 41.2% respectively. Compounds isolated from the chloroform-methanol extract by bioactivity-guided fractionation (quinovic acid glycosides, ursolic and oleanolic acid, 5α-carboxystrictosidine) showed only weak activity (at max. 33% at a dose of 20 mg/kg b.w.) compared to the most effective fraction (46.8%, 4.2 mg/kg b.w.) [Aquino 1991].

A quinovic acid glycoside fraction of cat´s claw bark (100 mg/kg b.w., i.p.) significantly ($p<0.001$) reduced IL-8 levels in the bladder of mice with cyclophosphamide-induced haemorrhagic cystitis. It prevented the increased expression of purinergic P2X7R receptors ($p<0.05$) and reduced the massive migration of neutrophils measured as a decrease in myeloid peroxidase activity ($p<0.05$) in bladder tissue [Dietrich 2015].

Mitraphylline impaired the release of TNF-α by 50% when administered to mice orally at 30 mg/kg b.w. for 3 days before LPS stimulation. It also inhibited the release of IL-1α and -1β by nearly 70%. The production of the pleiotropic cytokine IL-4 by activated T-cells, mast cells or basophils was reduced by 40%, whereas IL-17 production was reduced by 50%. No impact on levels of other cytokines was observed [Rojas-Duran 2012].

Renoprotective effects
A study evaluating the renoprotective effect of cat's claw involved 4 groups of rats (n=7 each); 2 control groups: one submitted to laparotomy (sham control), one submitted to 45 minutes of renal clamping causing renal ischaemia; and two treatment groups, administered an aqueous dry extract (20 mg, p.o., 1 x day) for 5 days prior to either the laparotomy or renal clamping. In the untreated ischaemic animals creatinine clearance was significantly reduced (0.17 vs. 0.54 ml/min) and the excretion of urinary peroxides was increased (11 vs. 3 nmol/g) compared to both treated groups and the sham control ($p<0.05$). Excretion of malondialdehyde was increased in the ischaemic group compared to the sham control (281 vs. 98 nmol/g; $p<0.05$) and decreased by the treatment of laparotomized rats (108 nmol/g) or ischaemic rats (151 nmol/g) ($p<0.05$) [Vattimo 2011].

Antiproliferative and cytotoxic effects
An aqueous dry extract (1 g /100 mL, 37°C, 0.43% pentacyclic oxindole alkaloids) inhibited tumour growth in mice with Lewis lung carcinoma when administered i.p. at 0.5 mg/day (n=6) and 5 mg/day (n=5) on 21 consecutive days ($p=0.0009$). The number of leukocytes in blood samples collected on the last day of treatment was significantly decreased ($p=0.00002$) in the group (n=6) treated with 0.05 mg/day. No differences were found in any of the groups concerning erythrocytes, platelets or haemoglobin. No antitumour activity was observed when animals were treated with an ethanolic dry extract (3.6% pentacyclic oxindole alkaloids) or an alkaloid enriched fraction (51.7% pentacyclic oxindole alkaloids) at 0.05 and 0.5 mg/day. Interestingly, the aqueous extract was the least active preparation when tested in vitro in cell lines (Lewis lung carcinoma: IC_{50}=461.26 µg/mL), whereas alkaloid-rich preparations were the most active (IC_{50}=25.06 µg/mL) [Pilarski 2010].

In a further study, a 70% hydroalcoholic dry extract (5.03% alkaloids) reduced the growth of murine carcinosarcoma in rats when administered by gavage at 10, 50 or 100 mg/kg b.w. for 14 days (starting at day 1 after tumour inoculation) by 46, 58 and 64% respectively ($p<0.05$). The treatment did not reverse the increase of blood levels of lactate dehydrogenase and gamma-glutamyltranferase, although all doses were effective in reducing urea plasma levels ($p<001$). Without treatment the tumour induced significant changes in all hepatic enzymes related to oxidative stress; catalase was reduced by 79%, superoxide dismutase increased by 252% and glutathione-S-transferase decreased by 59% compared to the baseline group. Treatment with the extract normalized the activities of these enzymes, in the case of superoxide dismutase only the highest dose (100 mg/kg b.w.) was effective. In the tumour tissue, catalase and superoxide dismutase activity were decreased by the treatment in all groups ($p<0.05$). No significant differences were found in activity of glutathione-S-transferase, reduced glutathione levels and lipid peroxidation [Dreifuss 2010].

Antimutagenic activity
Repair of DNA strand breaks 3 h after 12 Gy whole body irradiation was significantly ($p<0.05$) improved by daily oral treatment of rats with a purified aqueous extract (0, 40 and 80 mg/kg b.w.) for 8 weeks [Sheng 2000a].

In a consecutive study, DNA strand breaks were induced by 3 x 2 mg/kg b.w. doxorubicin (DX) applied i.p. at 24 h intervals. On day 10 after the first injection, spleen single cell suspensions were prepared and DNA single strand breaks were evaluated. Rats supplemented daily with 80 mg/kg b.w. of the extract (by gavage, starting 24 h after the last DX injection) showed a significant increase of DNA repair ($p<0.05$), no difference was found for the group treated with 40 mg/kg [Sheng 2000b].

The frequency of sister-chromatid exchanges was significantly lower (3.10-4.53; $p\leq0.05$) in mice administered with both i.p. pteropodine at 100-600 mg/kg b.w. and DX (10 mg/kg b.w.) compared to DX alone (14.06). Micronucleated polychromatic erythrocytes were significantly ($p\leq0.05$) reduced after 24h, from 19.1 in the DX group to 2.1-7.6 in the pteropodine groups) and after 96h, from 22.8 in the DX group to 3.0-6.0 in the pteropodine groups [Paniagua-Perez 2009].

Antinociceptive activity
Pre-treatment of mice with an alkaloid fraction of cat´s claw bark at 10, 30 and 100 mg/kg b.w. (i.p.) caused a significant and dose dependent reduction in the number of abdominal writhing responses by approximately 54, 72 and 97% when compared to vehicle-treated control ($p<0.01$). In the capsaicin test, a statistically significant reduction in the response to the noxious stimulus by 11, 66 and 94% ($p<0.01$) was observed in the pre-treated groups. Formalin induced responses were reduced by 8-94% ($p<0.05$ and 0.01) at doses of 10 - 300 mg/kg b.w. in the early phase (0-5 min after formalin injection) and 28-100% after 15-30 min. The antinociceptive action in the formalin test was significantly ($p<0.01$) reversed by i.p. pre-treatment of animals with ketanserin, but not by naltroxenone, atropine, prazosin, yohimbin, L-arginine or reserpine indicating the involvement of interactions with 5-HT_2 receptors. In the tail flick test, i.p. treatment of the animals with 300 mg/kg b.w. caused a significant increase in latency by 192% ($p<0.01$ after 120 min) and in the hot plate test by 311% ($p<0.01$). The motor response of animals was not affected [Jürgensen 2005].

A quinovic acid glycoside fraction of cat´s claw bark significantly inhibited nociceptive responses ($p<0.05$) in mice with cyclophosphamide induced haemorrhagic cystitis 4 h after i.p. administration (20-100 mg/kg b.w.), but not in healthy animals [Dietrich 2015].

Effects on CNS
An alkaloid fraction of cat´s claw bark (10-20 mg/kg b.w., i.p.), single alkaloids (10-40 mg/kg b.w., i.p.) as well as the muscarinic receptor agonist oxotremorine (0.01 mg/kg b.w., i.p.) significantly ($p<0.05$) attenuated the deficit in passive avoidance response in mice induced by scopolamine (3 mg/kg b.w., i.p.). Locomotor activity was not impaired by scopolamine or the alkaloids. Isopteropodine (20 mg/kg b.w., i.p.) also blocked the impairment of passive avoidance performance by the nicotinic receptor antagonist mecamylamine (15 mg/kg b.w., i.p.) and the N-methyl-D-aspartate receptor antagonist (±)-3-(2-carboxypiperazin-4-yl)-propyl-1-phosphonic acid (CPP, 7.5 mg/kg b.w., i.p.), but did not affect the deficit caused by diazepam (2 mg/kg b.w., i.p.). Rhynchophylline significantly reduced the mecamylamine-induced deficit but failed to attenuate effects of CPP and diazepam ($p<0.05$) [Mohamed 2000].

Effect on metabolic activity of blood granulocytes
An aqueous extract (1 g/10 mL, 0.43% alkaloids) administered to mice p.o. in 7 daily doses of 200 µg significantly stimulated granulocyte activity by 100% compared to the control (n=10 in each group, $p<0.001$) whereas an ethanolic extract (1g/10 mL, 3.48% alkaloids) showed a slightly inhibitory effect on O_2-production and leukocyte counts [Nowakowska 2010].

Effect on endometriosis
Endometriosis was induced in twenty-four female rats by auto-transplantation techniques. Ten animals were treated with 32 mg/day of a cat´s claw bark extract (32 mg/mL) by gavage and 12 animals with 0.9% saline solution (1mL/100g b.w.) for 14 consecutive days. The initial average volumes of the autotransplants did not differ between the groups ($p=0.18$), but the final average volumes were significantly different ($p=0.001$). There was an increase (from 38.1 to 75.7 mm^3, $p=0.01$) between the initial and final average volumes in the control group. Treatment with cat´s claw bark caused a marked reduction in the growth over time (from 45.5 to 27.3 mm^3, $p=0.009$). Histologically, in the treatment group, six rats had a well-preserved epithelial layer (60%), three (30%) mildly preserved epithelium and one (10%) poorly preserved epithelium. The epithelial layer occasionally presented sporadic epithelial cells. The control group presented seven cases (58.3%) of well-preserved epithelial cells and five cases (41.7%) of mildly preserved epithelial cells [Neto 2011].

Pharmacological studies in humans
Considering the comparable contribution of constituents in cat´s claw bark and root as well as the traditional use of both parts, studies are included in which preparations of the root or root bark were utilized:

Increase of lymphocytes in humans
Thirteen otherwise untreated HIV-patients received 20 mg/day of a hydrochloric acid root extract (10:1, 12 mg pentacyclic oxindole alkaloids per g). Results of blood tests were obtained at the beginning and after 2.2-5.0 months of treatment. Low leukocyte numbers (<4000 per µL, 2 of 13 patients) were raised and high leukocyte numbers (>9000 per µL, 2 of 13 patients) were lowered. The relative and absolute lymphocyte count increased significantly in all test persons (mean value: from 24.0% to 33.7%, $p=0.002$) [Keplinger 1999].

Persistent response to pneumococcal vaccine
A randomized study was carried out in male volunteers (age 40-60, n=23) to investigate the response to a polyvalent pneumococcal polysaccharide vaccine. One group (n=11) was treated with a daily dose of 2 x 350 mg of a purified aqueous extract for two months, the second group (n=12) did not receive any treatment. On day 30 of the study vaccination was performed

and the level of natural immunization was characterized (control group: 23.5%, treatment group: 33.9%, $p<0.05$). On day 60 of the study the cat´s claw bark treatment was stopped. In both groups immunization was achieved, with immunization levels of 72.8% for the control and 52.3% for the treatment group ($p<0.05$). Five months after vaccination, pneumococcal immunity was stable in the cat´s claw group, whereas the control group experienced a clear decrease ($p<0.01$). Blood analysis during the treatment showed that most of the haematological parameters were unaffected, only the lymphocyte/neutrophil ratio was increased [Lamm 2001].

Antimutagenic activity
Enhancement of DNA repair by cat's claw bark was investigated in twelve volunteers in a randomized study. One group received 250 mg per day of a purified aqueous extract for 8 weeks, the second 350 mg and the third group was the control. DNA repair after induction of DNA damage by a standard dose of hydrogen peroxide was measured in freshly prepared peripheral blood lymphocytes 3 times before and 3 times after administration. No differences were found concerning resistance to DNA damage. However, a statistically significant increase in DNA repair was observed (12-15%, $p<0.05$) after treatment. Furthermore, a tendency towards increased PHA induced lymphocyte proliferation was found in both verum groups [Sheng 2001].

Two 35 year old healthy donors, a smoker (approximately 20 cigarettes a day for 15 years) and a non-smoker, were treated for 15 days with a decoction of cat's claw bark (about 6.5 g/day). The urine was tested in the Ames-test, with and without activation by β-glucuronidase. The non-smoker's urine did not show any mutagenic activity before, during and after the treatment. The smoker's urine, however, had mutagenic activity before treatment, which was markedly decreased by the treatment (effect persisted 8 days after treatment) [Rizzi 1993].

Clinical studies

Effect on side effects of chemotherapy
The effectiveness of cat´s claw bark in reducing adverse effects of chemotherapy, particularly neutropenia and leukopenia, was studied in 40 breast cancer patients in a randomized clinical trial. All patients had undergone complete breast cancer resection (invasive ductal carcinoma stage II) and were going to begin adjuvant chemotherapy with a doxorubicin-based scheme for six cycles of 21 days. One group (designated as A, n=20) received the 6 cycles of chemotherapy, the second group (designated as B, n=20) received additionally cat´s claw bark (3x100 mg of a 70% hydroethanolic dried extract, 2.57% pentacyclic oxindole alkaloids, no tetracyclic derivatives). Twenty healthy women participated as the control group. At day zero no significant differences in haematological parameters were observed between the three groups.

A significant reduction in the leukocyte and neutrophil counts was observed in group A during the treatment (leukocytes from 6653 ± 1158 to 3247 ± 1117 cells/mm^3, $p<0.05$; neutrophils from 3588 ± 1081 to 1083 ± 368 cells/mm^3, $p<0.05$). Whereas the values of group B (leukocytes from 6800 ± 1458 to 5469 ± 1626 cells/mm^3, neutrophils from 3496 ± 1108 to 4016 ± 1545 cells/mm^3) remained close to the healthy control values at day 0 (leukocytes 6800 ± 1458 cells/mm3, neutrophils 3510 ± 1077 cells/mm3).

The lymphocyte number was reduced in both groups of cancer patients compared to the control ($p<0.05$). Monocyte counts (control group 487.6 cells/mm3) were not significantly changed by the treatment in group A (from 541 ± 161 to 500.9 ± 226) but were increased in group B (from 515.3 ±169 to 817.0 ± 444.6 cells/mm^3, $p<0.05$).

No significant differences between the patient groups were observed concerning immune response and antioxidant defence. The results of the Comet assay suggested a protective effect of cat´s claw bark on DNA during the treatment. At day 0 no differences were observed between the patient groups. At the end of the sixth cycle, however, the Comet assay index was significantly lower in group B ($p<0.05$) compared to group A [Araujo 2012].

In a randomized interventional trial, the effectiveness of cat´s claw bark in minimizing the side effects of chemotherapy and improving the antioxidant status of colorectal cancer patients was studied. Patients (n=43) who had undergone complete resection of their cancer (stage IIB, III or IV) and due to start chemotherapy with 5-fluorouracil/leucovorin and oxaliplatin (FOLFOX4, 6 cycles of 15 days) were randomly divided into 2 groups. The verum group (A, n=20) was treated with chemotherapy and cat´s claw bark (3x100 mg of a 70% hydroethanolic dried extract, 2.57% pentacyclic oxindole alkaloids, no tetracyclic derivatives), group B (n=23) received only chemotherapy. Administration of cat´s claw bark was suspended on chemotherapy treatment days due to possible interactions. No significant differences were observed in haematological parameters (haemoglobin, MCH, MCV, white blood cells and platelets count) between the two groups. Cat´s claw supplementation also did not change oxidative stress values or activity of antioxidant enzymes (catalase and superoxide dismutase), DNA damage at the level of eukaryotic cells and did not affect immunological parameters [Farias 2012].

In a prospective, single-centre, open-label phase II study, the potential of cat´s claw root bark for symptomatic management of terminal cancer patients was assessed. Patients (n=51) with various solid tumours, without any further therapeutic options, were treated with a dry extract of cat´s claw root bark (3x100 mg, 5.0% total alkaloids) for 8 weeks. The average overall quality of life ($p=0.0411$) and social functioning ($p=0.0341$) improved as assessed by the European Organization for the Research and Treatment of Cancer Quality of Life Questionnaire (version 3). Improvement in fatigue ($p=0.0496$) was assessed by the Chalder Fatigue Questionnaire. Other symptoms such as insomnia, pain, lack of appetite and body weight remained unchanged. No changes were observed in laboratory test results (complete blood count, kidney function, ALT, AST, ALP, GGT, bilirubin) and inflammatory parameters (C-reactive protein, erythrocyte sedimentation rate, α-1-acid glycoprotein) and cytokines (IL-1, IL-6 and TNF-α). No tumour response was detected according to the Response Evaluation Criteria in solid tumours but the disease stabilized for more than 8 months in four participants. The medication was well tolerated by most patients, three gastrointestinal adverse events were classified as being more severe, two of which may be attributed to the treatment [Carvalho Lopes de Paula 2015].

Effect on mild Alzheimer´s disease
In a randomized, placebo controlled pilot study, the effect of a proprietary extract of cat´s claw bark or root (fraction of a methanol extract, no further details) in mild Alzheimer´s disease was investigated. Patients (n=20) were treated with the extract at a dose of 350 mg three times daily for a year, while 20 patients received a placebo. No significant differences were observed between the groups concerning mini-mental state examination and Alzheimer disease assessment scale. The cerebrospinal fluid β-amyloid level, as well as the outcome of MRI measurements (hippocampal, temporal and total brain volume), were not significantly different at 3 and 12 months [Quinn 2004].

Effect on denture stomatitis
Forty-eight patients with denture stomatitis type II, all denture wearers for at least 1 year and in good general health, were

randomly assigned into 3 groups to receive either 2% miconazole gel (positive control, n=15), 1.5% hydroxyethyl cellulose gel (placebo, n=16) or 2% cat´s claw bark gel (no further details, experimental group, n=17). All patients received their treatment on admission (day 0) and were told to apply the gel (2.5 mL = 1 teaspoon) to the base of the denture after meals, 3 times daily for 1 week. Denture stomatitis level as well as fungal load (*Candida* sp.) of the mucosa and denture were recorded on days 0, 7 (after 1 week of treatment) and 14 (1 week after end of treatment). Severity of stomatitis and fungal load were reduced at day 7 and 14 in all groups ($p<0.05$), but with no significant differences between the groups [Tay 2014].

Effect on active rheumatoid arthritis
Forty patients suffering from rheumatoid arthritis and undergoing sulfasalazine or hydroxychloroquine treatment were enrolled in a randomized 2 phase study for 52 weeks. During the first phase (24 weeks, double-blind, placebo-controlled) patients (n=21) were treated with cat's claw (3 x 20 mg of an aqueous acid dried root extract, 1.47% pentacyclic oxindole alkaloids, no tetracyclic derivatives) or placebo (n=19). Comparison of the groups after the first phase showed that patients in the verum group had a greater reduction in the number of painful joints than those of the placebo group (by 53.2 vs. 24.1%, p=0.044). A reduction of tender joints (p=0.001), Ritchie Index (p=0.002) and of the duration of morning stiffness (p=0.002) was observed compared to baseline values, whereas in the placebo patients, the number of tender joints, Ritchie Index and duration of morning stiffness were not significantly reduced. No changes were observed for the number of swollen joints, patient assessment of disease activity and pain. The laboratory variables were unchanged except an increased rheumatoid factor (RF) level in the placebo group (p=0.041) (other parameters: CRP, antinuclear antibodies, complete blood count, hepatic and renal variables).

In the second phase of the study (28 weeks) all patients received the extract. In the former verum group, a further reduction of symptoms was found in the second phase. In patients who received the extract only in phase two, there was a reduction in the number of painful joints (p=0.003), number of swollen joints (p=0.007) and Ritchie Index (p=0.004) compared to the end of phase 1. None of the further observed changes reached statistical significance [Mur 2002].

Pharmacokinetic properties
The alkaloid mitraphylline was stable in simulated gastric fluid (pH 1.2), but unstable in simulated intestinal fluid (pH 6.8; 13.6% degradation after 2 hours). It was subjected to efflux-mediated P-glycoprotein in both Caro-2 and MDR-MDCK monolayers which might limit its intestinal absorption when administered orally. It was metabolized by human liver microsomes with half-lives of 50 min (no details on metabolites). Plasma protein binding was determined by equilibrium dialysis (<90%) [Manda 2014].

Preclinical safety data

Mutagenic effects
No mutagenic effects of different extracts (light petroleum, chloroform, chloroform-methanol 9:1, methanol and water) and chromatographic fractions of cat's claw bark were found in the Ames-test, with and without activation by β-glucuronidase (<100 µg/plate) [Rizzi 1993].

No genotoxic effects of a cat´s claw aqueous extract (plant part not specified) were observed at 0 - 1.9 mg/mL (calculated as dry plant material / mL water) using the somatic mutation and recombination test in wings of *Drosophila melanogaster* [Romero-Jimenez 2005].

Cytotoxic effects
Aqueous extracts (500 mg/mL) did not show any toxic effects in Chinese hamster ovary cells and the bacteria *Photobacterium phosphoreum* in the neutral red assay, tetrazolium assay and microtex test as well as on total protein content (concentrations 10-100 mg/mL) [Santa 1997].

No effect on cell viability was observed after administration of 25-200 mg/mL of an aqueous cat´s claw extract (20g/L, diluted 1:4) in epithelial cells (HT29) and macrophages (RAW 264.7) [Sandoval 1998].

Acute and chronic toxic effects
The LD_{50} of a water/ethanol extract (4:1, 4% alkaloids; no further information; 0.63-5 g/kg b.w.) was found to be > 5 g/kg b.w., the maximum tolerable dose was 2.5-5 g/kg b.w., as sedation and diarrhoea were noticed [Sheng 2000a].

Administration of an aqueous root extract to mice (16.6:1, 3.5% pentacyclic oxindole alkaloids) resulted in lethargy and piloerection. Two of ten mice died within 4 hours of treatment. Autopsy revealed gastro-intestinal haemorrhage and pallor of the liver and spleen. Recovery of survivors was complete within five days after treatment. The mice showed normal body weight gains and normal autopsy findings. The acute LD_{50} of the aqueous extract in mice was greater than 16 g/kg b.w. [unpublished data, cited in Keplinger 1999].

A daily dose of 1 g/kg b.w. (aqueous hydrochloric acid root extract, 10:1, 0.75% oxindole alkaloids) administered p.o. for 28 days caused a slight increase in percentage of lymphocytes and decrease in neutrophil granulocytes. Furthermore, an increase of relative weight of the kidneys in rats was observed. The histology of kidneys was normal. No other findings and no mortalities were observed during the study [unpublished data, cited in Keplinger 1999].

No toxic signs or symptoms, and no differences in food consumption and body weight, were observed in rats after administration of up to 80 mg/kg b.w. of a purified aqueous extract (daily single dose, gavage) for 8 weeks or a dose of 160 mg/kg b.w. for 4 weeks. No differences in organ weight (heart, liver, spleen, and kidney) and no pathological changes were noticed in either group. When a single dose of a purified aqueous extract (up to 8 g/kg b.w.) or capsules containing bark powder (up to 2 g/kg b.w.) was administered to rats (n=5) by gavage, no toxic symptoms or deaths occurred within 2 weeks. Another aqueous cat´s claw bark extract (4:1; 160 mg/kg b.w., as daily single dose for 4 weeks) caused significant reduction in body weight ($p<0.05$) and food consumption ($p<0.01$), but relative organ weights were unchanged [Sheng 2000a].

After treatment of BALB/c male mice once a day with 125, 500 or 1250 mg/kg b.w. of a 50% hydroalcoholic extract (2.9% oxindole alkaloids) for 28 days (no further treatment), no treatment-related mortality and no abnormalities with respect to their coat, eye colour, touch response, strength, salivation, body weight gain and water or food consumption were observed. The bone marrow, lymph nodes, kidneys and liver did not exhibit any significant histological alterations [Domingues 2011a].

Clinical safety data
In a human volunteer study (n=4), no negative effects were observed after treatment with 350 mg/day (5 mg/kg b.w.) of a purified aqueous extract for 6 weeks on haematological analysis, body weight and work attendance. No toxic symptoms were observed [Sheng 2000a].

No negative side effects were observed during and after the

treatment of 23 male volunteers with 250 mg or 350 mg of the same extract for 2 months, or of 12 volunteers for 8 weeks in another study, according to medical examination, clinical chemistry and blood cell analysis [Sheng 2001, Lamm 2001].

Cat´s claw bark related toxic side effects were not observed in colorectal cancer patients (n=20), who had undergone complete resection of their cancer (stage IIB, III or IV) after treatment with chemotherapy with 5-fluorouracil/leucovorin and oxaliplatin (6 cycles of 15 days) and cat´s claw bark (3x100 mg of a 70% hydroethanolic dried extract, 2.57% pentacyclic oxindole alkaloids, no tetracyclic derivatives) within 12 weeks (clinical symptoms, serum clinical chemistry, whole blood analysis, leukocyte differential counts) [Farias 2012].

In a study involving 21 patients with rheumatoid arthritis undergoing sulfasalazine or hydrochloroquine therapy and treatment with cat's claw (3 x 20 mg of an aqueous acid-extracted dry root extract, 73.5% pentacyclic oxindole alkaloids, no tetracyclic derivatives), 12 adverse events occurred. One patient from the verum group withdrew from the study due to gastritis and one from the placebo group (n=19, 12 adverse effects) due to diarrhoea. In a second phase of the study all patients (n=40) were treated with the plant extract. Seven further adverse events were seen, but none could be clearly attributed to the drug intake. No major side effects were observed [Mur 2002].

In another study, patients (n=51) with various solid tumours without further therapeutic options were treated with a dry extract of cat´s claw root bark (3x100 mg, 5.0% total alkaloids). A number of mild adverse events were observed; in general the medication was well tolerated. Three gastrointestinal adverse events were classified as being more severe, two of which may be attributed to the treatment [Carvalho Lopes de Paula 2015].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
CCl_4	carbon tetrachloride
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase

INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E

URTICAE FOLIUM/HERBA 2018

Nettle Leaf/Herb

DEFINITION

Nettle Leaf/herb consists of the whole or cut dried leaves of *Urtica dioica* L., *Urtica urens* L., or a mixture of the 2 species. It contains minimum 0.3 % for the sum of caffeoylmalic acid and chlorogenic acid expressed as chlorogenic acid (dried drug).

The material complies with the monograph of the European Pharmacopoeia [Nettle leaf].

CONSTITUENTS

Caffeic acid esters, principally caffeoylmalic acid in *Urtica dioica* (up to 1.6%) but none in *Urtica urens*; chlorogenic acid (up to 0.5%) and small amounts of neochlorogenic acid and free caffeic acid in both species.
Flavonoids, principally kaempferol, isorhamnetin, quercetin and their 3-rutinosides and 3-glucosides. Anthocyanins, such as peonidin 3-*O*-rutinoside, peonidin 3-*O*-(6''-*O*-p-coumaroyl glucoside), rosinidin 3-*O*-rutinoside. 13-hydroxyoctadecatrienoic acid, diastereoisomeric 3-hydroxy-α-ionol glucosides, scopoletin, sitosterol and its 3-glucoside, glycoprotein, free amino acids (30 mg/kg).
Minerals (ca. 18% expressed as ash) including potassium (1.8-2.0%) and silicon (0.9-1.8%). The potassium-sodium ratio has been determined as 63:1 in the unprocessed drug.
Stinging hairs on the leaves contain acetylcholine, histamine, 5-hydroxytryptamine (serotonin) and small amounts of leukotrienes.
[Collier 1956; Piekos 1976; Lutomski 1983; Chaurasia 1987; Ellnain-Wojtaszek 1988; Czarnetzki 1990; Bauer 1997; Budzianowski 1991; Lapke 1993; Neugebauer 1995; Schomakers 1995; Szentmihalyi 1998; Schulze-Tanzil 2002].

CLINICAL PARTICULARS

Therapeutic indications

Adjuvant in the symptomatic treatment of arthritis, arthroses and/or rheumatic conditions [Ramm 1995,1996,1997; Hansen 1996; Enderlein 1997; Wolf 1998; Randall 2000].

Nettle leaf or herb is also used as to enhance renal elimination of water in inflammatory complaints of the lower urinary tract [Schilcher 1988,1992; Jaspersen-Schib 1989; Czygan 2002].

Posology and method of administration

Dosage

Internal use

Adults: Hydroalcoholic extracts corresponding to 8-12 g of nettle leaf daily, divided into 2-3 doses [Ramm 1995,1996,1997; Hansen 1996; Wolf 1998]; 3-5 g of the drug as an infusion up to three times daily [Urtica BHP 1983; Van Hellemont 1988 Jaspersen-Schib 1989; Schilcher 1992]; tincture 1:5 (25% ethanol) 2-6 ml three times daily [Urtica BHP 1983]; 15 mL of fresh juice up to three times daily [Kirchhoff 1983].

External use

Adults: Fresh nettle leaf applied to the skin in the area of pain for 30 seconds once daily [Randall 2000].

Method of administration

For oral or topical administration.

Duration of use

No restriction.

Contraindications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicinal products and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Gastrointestinal upset or allergic response in a few individuals after oral use [Ramm 1995,1997; Hansen 1996; Enderlein 1997; Wolf 1998].

Overdose
No case of overdose reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Anti-inflammatory activity
A hydroethanolic extract (6.4-8:1) and its main phenolic constituent, caffeoylmalic acid, were tested for inhibitory potential on the biosynthesis of arachidonic acid metabolites by rat leukaemic basophilic granulocytes (RBL-1 cells). The extract (0.1 mg/mL) and the isolated acid (1 mg/mL) showed partial inhibitory effects of 20.8% and 68.2% respectively on the 5-lipoxygenase-derived synthesis of leukotriene B_4; caffeoylmalic acid exhibited concentration-dependent activity with an IC_{50} of 85 µg/mL. Both the extract and the acid showed strong concentration-dependent inhibition of the synthesis of cyclooxygenase-derived prostaglandins (IC_{50} of 92 µg/mL for the extract and 38 µg/mL for the acid) [Obertreis 1996].

The same extract significantly and dose-dependently reduced LPS-stimulated release of two proinflammatory cytokines, TNF-α and IL-1β, in human whole blood from 6 healthy volunteers. After 24 hours, TNF-α concentration was reduced by 50.8% and IL-1β concentration by 99.7% using the highest tested extract concentration of 5 mg/mL ($p<0.001$); after 65 hours the inhibition was 38.9% and 99.9% respectively ($p<0.001$). The extract and LPS stimulated the release of IL-6 in human blood when used separately, but showed no additive effect when used simultaneously; IL-6 acts antagonistically to IL-1β, decreasing IL-1β-induced PGE_2 synthesis by fibroblasts and synovial cells. Selected constituents of nettle leaf (caffeoylmalic acid, chlorogenic acid, caffeic acid, quercetin and rutin), tested in the same way did not influence the release of TNF-α, IL-1β or IL-6 at concentrations up to 5×10^{-5} mol/litre [Obertreis 1996].

Th1 and Th2 cells (T helper cells) have cytokine patterns which regulate cell-mediated and humoral immune responses. Th1 cells produce IL-2 and IFN-γ, proinflammatory cytokines that induce a cascade of inflammatory responses. Th2 cells produce IL-4, IL-5 and IL-10. The cytokine patterns of these Th effector cells are antagonistic and cross-regulated; thus agents that promote Th1 cytokine expression inhibit Th2 cytokine production and vice versa. The water-soluble fraction from a nettle leaf extract (6.4-8.1:1) significantly inhibited phytohaemagglutinin (PHA)-stimulated production of Th1-specific IL-2 ($p<0.01$) and IFN-γ ($p<0.02$) in human peripheral blood mononuclear cells (PBMC) in a dose-dependent manner, by 50 ± 32% and 77 ± 14% respectively at the highest concentration tested (equivalent to 400 µg/mLexpressed as the total extract). The dose-dependent inhibiting effect on IL-2 and IFN-γ expression was also detected by reverse transcriptase-polymerase chain reaction in PHA-stimulated PBMC. In contrast, the extract fraction enhanced the secretion of Th2-specific IL-4 by PHA-stimulated PBMC, but dose-dependently decreased IL-10 secretion [Klingelhoefer 1999].

Incubation of HeLa cells with various concentrations of an extract (6.4-8.1:1) before stimulation with TNF demonstrated that the extract potently and dose-dependently inhibited the formation of an NF-κB DNA complex and inhibited NF-κB reporter gene activity; in both cases even stronger inhibition was observed with a water-soluble fraction of the extract. Pretreatment with the water-soluble fraction also inhibited NF-κB activation in stimulated Jurkat T, L929 fibrocarcinoma and MonoMac6 cells. Further experiments with stimulated HeLa and Jurkat T cells suggested that the water-soluble fraction of the extract inhibits NF-κB activation not by modification of DNA binding but by preventing the degradation of its inhibitory subunit IκB-α [Riehemann 1999].

In an *ex vivo/in vitro* study, 2 x 670 mg of an extract (6.4-8.1:1) was administered daily for 21 days to 18 healthy volunteers from whom blood samples were taken at 0, 7 and 21 days. Testing of the whole blood samples revealed, in comparison with day 0 values, significant reductions in LPS-stimulated release of two cytokines, TNF-α and IL-1β: at day 7 and day 21, release of TNF-α had decreased by 14.6% ($p<0.01$) and 24.0% ($p<0.001$), and IL-1β by 19.2% ($p<0.01$) and 39.3% ($p<0.001$), respectively. When a water-soluble fraction from the same batch of nettle leaf extract, at various concentrations, was incubated for 24 hours with 0-, 7- and 21-day whole blood samples from the volunteers, concentration-dependent (and time-dependent in the sense of 7- and 21-day samples from the volunteers) inhibition of LPS-induced release of the same cytokines was demonstrated; at the highest concentration of extract fraction (160 µg/mL) incubated with 21-day blood samples, release of TNF-α decreased by 79.5% ($p<0.001$) and IL-1β by 99.2% ($p<0.001$) compared to day 0 values of blood untreated with the extract fraction [Teucher 1996].

An extract, prepared as 0.25 mg/mL of a lyophilized aqueous extract in water, produced 93% inhibition of PAF-induced exocytosis of elastase from human neutrophils. The same extract (0.2 mg/mL) showed no activity in a test for inhibition of the biosynthesis of prostaglandins [Tunon 1995].

A dry 95%-isopropanolic extract (19-33:1) and 13-hydroxy-octadecatrienoic acid (a constituent present in the extract) at 10 µg/mL significantly suppressed IL-1β-induced expression of matrix MMP proteins on cultured human chondrocytes: relative expression of MMP-1, MMP-3 and MMP-9 decreased by 63-96% ($p = 0.0014$ to 0.0057) with the extract and 60-88% ($p = 0.0078$ to 0.054) with 13-hydroxyoctadecatrienoic acid [Schulze-Tanzil 2002].

A dry 95%-isopropanolic extract (19-33:1) exhibited an immunosuppressant effect in preventing the maturation of cultured human myeloid dendritic cells (without affecting their viability), leading to reduced induction of primary T cell responses [Broer 2002].

Other effects
Aqueous extracts (not further specified) produced slight contraction followed by relaxation in isolated uterine smooth muscle from the non-pregnant mouse. Application of the extracts to uterine muscle from the pregnant mouse produced a diametrically opposed effect, increase of muscular tone and contractions of considerable amplitude [Broncano 1987].

Inhbitory effects of various extracts (petroleum ether, ethyl acetate, methanol and water) and flavonoid aglycone and flavonoid glycoside fractions (1 mg/mL) from *Urtica dioica* leaves on rat platelet aggregation induced by thrombin 0.5 U/mL were analysed. Only the ethyl acetate extract (60-80%), flavonoid aglycones (86.5%) and flavonoid glycosides (82.8%) were significantly ($p< 0.001$) active [El Haouari 2006].

The results from perfusion of glucose-containing Islets of Langerhans by an aqueous extract (10 g/200 mL) showed an increase in insulin secretion both in 2.8 and 16.7 mM solutions [Farzami 2003].

The antiproliferative activity of an aqueous extract of *Urtica dioica* at 0, 0.375, 0.75, 1.5, 2 and 3 mg/mL concentrations on MCF-7 cell line was tested after 24, 48 and 72 hrs. After 72 hrs a dose-dependent manner antiproliferative activity was observed (IC_{50}: 2 mg/mL). There was a significant difference in cell viability between 0.375 mg/mL and 0.75 mg/mL ($p< 0.05$) [Fattahi 2013].

The antioxidant activity of an aqueous extract of *Urtica dioica* was evaluated by MTT and showed significant activity ($p< 0.05$) at 3-12 mg/mL concentration [Fattahi 2013].

A hydroethanolic dry extract (not further specified) showed histamine receptor antagonist activity with an IC_{50} of 251 (±13) µg/mL and histamine receptor negative agonist activity with an IC_{50} of 193 (±71) µg/mL. It also showed inhibition of mast cell tryptase, COX-1, COX-2 and haematopoietic prostaglandin D2 synthase with IC_{50} values of 172 (±28), 160 (±47), 275 (±9) and 295 (±13) µg/mL respectively [Roschek 2009].

Ex vivo experiments
An ethanolic extract (5 g/100 mL) of *Urtica dioica* caused significant inhibition (25 µL, 50 µL ($p< 0.01$) and 100 µL ($p< 0.02$)) of adenosine deaminase activity in prostate tissue from patients with prostate cancer (Gleason scores 4-7) [Durak 2004].

In vivo experiments

Antidiabetic Activity
Normal and streptozotocin diabetic rats were injected i.p. with a fraction obtained from an aqueous extract of *Urtica dioica*. A significant ($p< 0.05$) rise in the level of serum insulin was observed after 60 min. Glucose level showed a decrease, initiated at 60 min and 120 min [Farzami 2003].

A hydroalcoholic extract (not further specified) of *Urtica dioica* was administered to Wistar rats at 100 mg/kg/day i.p. for five days and then hyperglycaemia was induced with streptozotocin. After five weeks, blood glucose concentrations were significantly ($p<0.05$) lower in the treatment group compared to an untreated diabetic group (303.6±100.6 and 454.7±34.5 respectively). The percentage of β-cells was significantly ($p<0.05$) higher in the treatment group compared to the untreated diabetic group (1.9 and 22.9 % respectively) [Golalipour 2007].

Hepatoprotective Activity
The effects of 14 days treatment with a hydroethanolic extract (80% ethanol; 50 and 100 mg/kg b.w. p.o.) of *Urtica dioica* were investigated in the liver of Swiss albino mice (8-9 weeks old). Significant increases were observed for the activities of cytochrome b5 (cyt b5), NADH-cytochrome b5 reductase (cytb5R; $p< 0.001$ at doses of 50 mg/kg and 100 mg/kg), glutathione S-transferase and DT-diaphorase ($p< 0.005$ at 50 mg/kg, $p< 0.05$ at 100 mg/kg), and glutathione peroxidase, glutathione reductase, superoxide dismutase and catalase ($p< 0.001$ at doses of 50 mg/kg and 100 mg/kg). Both treatment groups showed significantly lower activity of cytochrome P450, lactate dehydrogenase ($p< 0.001$), NADPH-cytochrome P450 reductase ($p< 0.005$, $p< 0.001$), total sulfhdryl groups ($p< 0.05$, $p< 0.005$) and protein bound sulfhydryl groups (100 mg/kg $p< 0.001$) [Özen 2003].

A study investigated the effects of 14 days treatment with a hydroethanolic extract (80% ethanol; 50 and 100 mg/kg b.w. p.o.) of *Urtica dioica* on hepatic aniline 4-hydroxylase (A4H), NADH and NADPH-NADH in Swiss albino mice (8-10 weeks old). Hepatic aniline 4-hydroxylase (A4H) cofactor requirements were significant at both doses for cofactors NADH ($p< 0.05$), NADPH-NADH at 50 mg/kg ($p< 0.01$) and at 100 mg/kg ($p< 0.005$), and not significant for NADPH at 50 mg/kg but significant at 100 mg/kg ($p< 0.01$). Also A4H activity on Mg^{2+} in mice was found to be significant at doses of 50 mg/kg ($p< 0.05$) and 100 mg/kg ($p< 0.005$), and on Ca^{2+} at 50 mg/kg ($p< 0.01$), but not significant at 100 mg/kg [Özen 2009].

Diuretic effects
The effects of continuous intravenous perfusion into anaesthetized rats for 1.25 hours of solutions (in isotonic 0.9% saline) of a dry aqueous extract at two dose levels, 4 mg/kg/hour or 24 mg/kg/hour, were compared with the effect of furosemide (as a control diuretic), similarly perfused at 2 mg/kg/hour. Compared to control periods (perfusion of saline only), the extract caused dose-dependent increases in diuresis (urine volume) of 11% and 84% (both $p<0.001$) and in natriuresis of 28% and 143% (both $p<0.001$) respectively, while furosemide increased diuresis by 85% and natriuresis by 155% (both $p<0.001$) [Tahri 2000].

No effect on diuresis or ion excretion could be demonstrated in rats after oral administration of an aqueous extract at a dose of 1 g/kg b.w. [Lasheras 1986].

Furthermore, no significant diuretic effect was observed during 2 hours after oral administration to rats of an unspecified ethanolic extract at 1 g/kg b.w., whereas urinary excretion increased significantly after intraperitoneal administration of 500 mg/kg [Tita 1993].

Although the potassium-sodium ratio of dried nettle leaf was determined as 63:1, the ratio in a decoction (2 g of dried leaf boiled in 200 ml of deionized water) was found to be much higher at 448:1 [Szentmihalyi 1998].

Spontaneous motility
An infusion and aqueous extract (3:1) produced dose-dependent reductions in spontaneous motility and body temperature in rats and mice when administered i.p. at doses of 1.739 and 3.748 g/kg b.w. for the infusion and 303 and 606 mg/kg for the extract [Broncano 1987]. An aqueous extract at a dose of 750 mg/kg led to a significant reduction in spontaneous activity in mice during the first 16 hours after administration [Lasheras 1986].

Hypotensive effects
In the perfusion experiments described above under *Diuretic effects*, the diuretic and natriuretic effects were accompanied by a dose-dependent hypotensive effect. Compared to control periods (perfusion of isotonic 0.9% saline only), perfusion of a dry aqueous extract (in isotonic saline) reduced arterial blood

pressure by 15% at 4 mg/kg/hour and 38% at 24 mg/kg/hour (both $p<0.001$); while furosemide at 2 mg/kg/hour reduced arterial blood pressure by 28% ($p<0.001$). The hypotensive effect was reversible within about 1 hour of recovery after the lower dose of extract or furosemide, but was persistent after the higher dose of extract, indicating a possible toxic effect at that dose level [Tahri 2000].

Nettle herb produced a rapid but only transient decrease of 31.7% on the blood pressure of anaesthetized rats after i.v. administration of an aqueous extract at a dose of 25 mg/kg b.w. [Lasheras 1986]. In cats, an aqueous extract (3.3:1) administered by cannula at a dose of 26.6 mg/kg b.w. produced a marked hypotensive effect and bradycardia, which was not compensated by subsequent administration of adrenaline [Broncano 1983].

Hyperglycaemic activity
Both an 80% ethanolic extract and an aqueous decoction, evaporated to dryness, resolubilized and administered to mice at the equivalent of 25 g drug/kg b.w. 2 hours prior to glucose load, produced hyperglycaemic effects in an oral glucose tolerance test [Neef 1995].

Analgesic activity
After administration of an aqueous extract at a dose of 1200 mg/kg, mice showed much greater resistance to thermal stimulation in the hot plate test at 55°C, taking 190% longer time to react than control animals [Lasheras 1986].

An ethanolic extract (not further specified) reduced the writhing response to phenylquinone in rats after oral (1 g/kg) and intraperitoneal (500 mg/kg) treatment but demonstrated no analgesic activity in the hot plate test [Tita 1993].

An *U. urens* extract (80% ethanol) showed significant anti-nociceptive activity in chemically induced mouse pain models; in the writhing test (96.5% inhibition at 250 mg/kg i.p., $p<0.01$), the formalin test (62.8% inhibition at 500 mg/kg p.o., $p<0.05$) and significant ($p<0.01$) antiinflammatory activity in the carrageenan-induced rat hind paw oedema test (41.5% inhibition at 300 mg/kg) [Marassini 2010].

Local anaesthetic activity
Local application to the rat tail of 0.05 mL of an aqueous extract (100 mg lyophilized extract per mL), in the same region as subsequent application of heat in the tail flick test, produced a local anaesthetic effect comparable to that of lignocaine [Lasheras 1986].

Clinical studies

Adjuvant treatment of arthritis, arthroses and/or rheumatic conditions
Five open, multicentric, post-marketing surveillance studies have been carried out on patients with arthritic or rheumatic complaints using a preparation containing a dry hydroethanolic extract (6.4-8:1) at a daily dosage of 2 x 670 mg (corresponding to 9.648 g of dried leaf per day). In each study a proportion of the patients also continued other therapies, primarily non-steroidal anti-inflammatory drugs (NSAIDs), while others received only the nettle leaf extract. Assessments were carried out through patient questionnaires and consultations with physicians. Overall, 80-95% of patients rated the efficacy of the extract, and 93-95% its tolerability, as good or very good [Ramm 1995,1996,1997; Hansen 1996; Wolf 1998]:

- 152 patients with rheumatic pains, of whom about 60% had degenerative disorders of joints, were treated in a 3-week study. Pain symptoms assessed by a visual analogue scale (VAS) improved in 70% of patients by at least one third: pain at rest by 50%, movement pain by 51%. In patients receiving only nettle leaf extract (n = 12) pain decreased by 43% [Ramm 1995].

- 219 patients, mainly with degenerative or inflammatory joint disorders, were treated in another 3-week study. Pain symptoms (VAS) improved by at least one-third in 70% of patients; in patients with pain of degenerative origin by about 50%. Patients taking only nettle leaf extract found it as effective as the extract + NSAIDs [Hansen 1996].

- 223 patients with arthritis (over 50% gonarthritis, 34% coxarthritis) were treated in a 6-week study. Pain intensity (VAS) decreased by 56% and objective assessment of all findings on joints (reddening, overheating, swelling, pressure pain and joint discharge) improved by 60-65% on average. A reduction in complaint symptoms of at least 33% from initial values was experienced by 75% of the patients and this was reflected in patients' responses to a Quality of Life questionnaire. Out of the 130 patients initially taking concomitant NSAIDs, 106 (81%) reduced or discontinued their NSAID dosage [Ramm 1997].

- 8955 patients suffering pain and impairment of mobility due to osteoarthritis or rheumatoid arthritis were treated in a 3-week study. The total symptom scores (1-5 point scales for pain at rest, exercise pain and restricted mobility) of 96% of patients decreased by 45% on average and no clinically relevant differences in efficacy were evident between the group taking only the extract compared to those continuing with NSAIDs or other therapy. 64% of those patients who initially continued NSAID treatment reduced (38%) or discontinued (26%) their NSAID dosage later in the study [Ramm 1996].

- 819 patients with gonarthritis were treated in a 12-month study. Symptoms such as pain, joint stiffness and impaired joint function, assessed by a quantitative gonarthritis-specific questionnaire, decreased by 61% on average. The frequency of each of 5 symptoms (swelling, pressure pain, reddening, joint discharge and overheating) decreased significantly ($p<0.001$) [Wolf 1998].

In an open, randomized 14-day study, patients with acute arthritis received daily either 2 × 100 mg of diclofenac (n = 17) or 50 mg of diclofenac and 50 g of a prepacked stewed nettle leaf purée (water content 95.5%, caffeoylmalic acid content 20 mg) (n = 19). Both groups also received the gastroprotective misoprostol (a prostaglandin analogue). The main criterion of the study was relative improvement in elevated serum levels of C-reactive protein, which decreased by about 70% in both groups. Assessments (verbal rating score 0-4) of physical impairment, subjective pain and pressure pain by patients, and stiffness by physicians, showed improvements in the range 52-77%, with no significant differences between the two groups [Enderlein 1997].

An exploratory study was carried out on the alleviation of pain by external application of fresh nettle leaves, which causes urtication. From analysis of recorded, semi-structured interviews between a doctor and 18 people who had tried this self-treatment for joint or muscle pains, 15 out of 18 claimed that nettle treatment worked on every application; 17 out of 18 reported pain relief after the first course of treatment and had found no other treatment as effective as nettle leaf. Onset of pain relief occurred in less than 24 hours in 11 out of 18 patients. The stinging sensation was reported by 14 out of 18 as 'not painful, with a not unpleasant warmth' and, other than

3 cases of localised numbness for 6-24 hours and a few rashes, no side effects were reported [Randall 1999].

Subsequently a randomized, double-blind, crossover study was carried out involving 27 patients with persistent osteoarthritic pain at the base of the thumb or index finger, none of whom had previously used nettle leaf as a treatment. Existing analgesic or anti-inflammatory treatments were continued during the study. A fresh leaf from pot-grown, non-flowering *Urtica dioica* or *Lamium album* (white deadnettle, as a placebo of similar appearance), handled through plastic, was applied to the affected area once daily for 30 seconds in a standard manner. One week of treatment was followed by a wash-out period of 5 weeks before one week of the alternative treatment. Compared to placebo, significantly greater reductions in scores were observed with nettle leaf on a visual analogue scale for pain ($p = 0.026$) and the Stanford health assessment questionnaire for disability ($p = 0.0027$). No serious side affects were reported and the localized rash and itching associated with nettle leaf was acceptable to 23 of the 27 patients [Randall 2000].

Diuretic effects
In an open 2-week study, 32 patients suffering from myocardial or chronic venous insufficiency were treated daily with 3 × 15 mL of nettle herb pressed juice. A significant increase in the daily volume of urine was observed throughout the treatment, the volume on day 2 being 9.2% higher ($p<0.0005$) than the baseline amount in patients with myocardial insufficiency and 23.9% higher ($p<0.05$) in those with chronic venous insufficiency. Minor decreases in body weights (about 1%) and systolic blood pressure were also observed. Serum parameters were unaffected [Kirchhoff 1983].

Antidiabetic effect
In a randomized, double-blind, placebo-controlled clinical trial, the effects of a dried hydroethanolic *Urtica dioica* extract (ethanol 70%, yield 20.24%) were examined in type 2 diabetic patients. Patients continued with their same dose of conventional oral antihyperglycaemic drugs during the trial. They received one capsule every 8 hours for 3 months, containing either 500 mg of the extract (n=46) or placebo (n=46). Effects on the blood levels of fasting glucose, postprandial glucose, glycosylated haemoglobin (HbA1c), creatinine and liver enzymes SGOT and SGPT, as well as on systolic and diastolic blood pressure were evaluated. Compared with placebo, the extract lowered the blood levels of fasting glucose, 2 hours postprandial glucose and HbA1c significantly ($p<0.001$, $p= 0.009$, and $p= 0.006$ respectively) without any significant effects on the other parameters ($p>0.05$) [Kianbakht 2013].

Antioxidant Effect
A randomized, double-blind, placebo-controlled trial involved 50 patients with type 2 diabetes, administered with either 100 mg/kg b.w. of a hydroethanolic extract (45% ethanol; 2.7 g dry matter per 1L extract) or placebo for 8 weeks. In blood samples collected after 8 weeks, *in vitro* Total Antioxidant Capacity (TAC) and Superoxide Dismutase (SOD) were significantly ($p<0.05$) increased in the intervention group compared to the control group [Namazi 2012].

Pharmacokinetic properties
No data available.

Preclinical safety data
The intraperitoneal LD_{50} of an aqueous extract of *Urtica dioica* herb in mice has been determined as 3.625 g/kg b.w. [Lasheras 1986].

An ethanolic extract of *Urtica dioica* herb showed low toxicity in both rats and mice after oral and intraperitoneal administration at the equivalent of up to 2 g of dried drug per kg b.w. [Tita 1993].

Clinical safety data
No serious adverse effects were reported from 5 clinical studies in which a total of 10,368 patients took 2 x 670 mg of a dry hydroethanolic extract (6.4-8:1), corresponding to about 9.7 g of dried leaf, daily for periods varying from 3 weeks to 12 months; the incidence of minor adverse effects (mainly gastrointestinal upsets or allergic reactions) was 1.2-2.7% [Ramm 1995-1997; Hansen 1996; Wolf 1998]. In a study where 19 patients received 50 g of a stewed nettle leaf purée daily for 14 days, 3 patients reported meteorism [Enderlein 1997].

A case of gynaecomastia in a man and a case of galactorrhoea in a woman were reported after consumption of 2-3 cups nettle tea daily for one month. However, the causal relationship was unclear [Şahin 2007].

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

URTICAE RADIX

Nettle Root

2015

DEFINITION

Nettle root consists of the whole, or fragmented, underground parts of *Urtica dioica* L., *Urtica urens* L., their hybrids or mixtures of these.

The material complies with the European Pharmacopoeia [Nettle Root].

CONSTITUENTS

Approx. 0.1% agglutinin (UDA), a lectin which can be separated into 11 isolectins and which contains 86 amino acid residues [Peumans 1984; Van Damme 1988; Broekaert 1989; Willer 1991, 1992; Balzarini 1992; Beintema 1992; Lerner 1992, Wagner 1994a; Frank 1998; Ganzéra 2005]; a mixture of polysaccharides, basically 2 glucans, 2 rhamnogalacturonans and 1 arabinogalactan [Willer 1992; Wagner 1992, 1994b; Frank 1998]; scopoletin, β-sitosterol, β-sitosterol glucoside and other sterols and sterol glucosides [Schilcher 1986; Chaurasia 1986a, 1987a,b; Frank 1998]; phenylpropanes (homovanillyl alcohol and its glucoside) as well as lignans such as (+)-neo-olivil and its derivatives, (–)-secoisolariciresinol, (–)-isolariciresinol and dehydrodiconiferyl alcohol, and lignan glucosides [Chaurasia 1986b, 1987a; Kraus 1990a,b; Ganßer 1995a,b; Schöttner 1997a,b; Orčić 2015]; ceramides [Kraus 1991a]; hydroxy fatty acids including (10*E*,12*Z*)-9-hydroxy-10,12-octadecadienoic acid [Kraus 1991b] and the isomeric 9,10,13-trihydroxy-11-octadecenoic and 9,12,13-trihydroxy-10-octadecenoic acids [Ganßer 1995a,b]; monoterpene diols and their glucosides [Kraus 1991c].

CLINICAL PARTICULARS

Therapeutic indications
Symptomatic treatment of micturition disorders (dysuria, pollakisuria, nocturia, urine retention) in benign prostatic hyperplasia (BPH) [Djulepa 1982; Tosch 1983; Schilcher 1988a,b, 1989, 1992; Stahl 1984; Vontobel 1985; Vahlensieck 1986, 1996; Vandierendounck 1986; Dathe 1987; Maar 1987; Bauer 1988; Feiber 1988; Friesen 1988; Goetz 1989; Jaspersen-Schib 1989; Belaiche 1991; Fischer 1992; Kaldewey 1995; Brom 1996; Engelmann 1996; Bracher 1997; Veit 1998; Chrubasik 2007; Pagano 2014] at stages I and II as defined by Alken [Alken 1973] or stages II and III as defined by Vahlensieck [Vahlensieck1996].

Posology and method of administration

Dosage

Daily dose: 4-6 g of the drug as an infusion [Schilcher 1992; Jaspersen-Schib 1989]; 300-600 mg of dried native extract (7-14:1, 20% V/V methanol) [Djulepa 1982; Tosch 1983; Stahl 1984; Vontobel 1985; Vandierendounck 1986; Dathe1987; Maar 1987; Bauer 1988; Feiber 1988; Friesen 1988; Fischer 1992; Brom 1996; Bracher 1997; Veit 1998; Pagano 2014] or 378-756 mg of dried native extract (12-16:1, 70% V/V ethanol) [Kaldewey 1995]; 4.5-7.5 mL of fluid extract (1:1, 45% ethanol) [Goetz 1989] or 15 mL of fluid extract (1:5, 40% ethanol) [Belaiche 1991]; comparable extracts at equivalent dosages.

Method of administration
For oral administration.

Duration of administration
No restriction.

Contra-indications
None known.

Special warnings and special precautions for use
All cases of difficulty in micturition require clarification by a physician and regular medical checks in order to rule out the need for other treatment, e.g.

E/S/C/O/P MONOGRAPHS

Stages of Benign Prostatic Hyperplasia as defined by Alken	Stages of Benign Prostatic Hyperplasia as defined by Vahlensieck
Stage I Dysuria, pollakisuria, possibly nocturia, reduction in projection of the urine stream, no residual urine (stage of compensation of the bladder musculature).	**Stage I** No micturition problems More or less marked BPH Urine stream: greater than 15 mL/s maximal flow No residual urine No bladder trabeculation
Stage II Same symptomatic as under I, except with residual urine (incipient decompensation of the bladder musculature).	**Stage II** Intermittent micturition problems (frequency, calibre of urine stream) More or less marked BPH Urine stream: between 10 and 15 mL/s maximal flow No or low (≤ 50 mL) residual urine No or incipient bladder trabeculation
Stage III Complete stoppage or overflow of the bladder (decompensation of the bladder musculature).	**Stage III** Permanent micturition problems (frequency, calibre of urine stream) More or less marked BPH Urine stream: less than 10 mL/s maximal flow Residual urine more than 50 mL Trabeculated bladder
	Stage IV Permanent micturition problems (frequency, calibre of urine stream) More or less marked BPH Urine stream: less than 10 mL/s maximal flow Residual urine more than 100 mL Overflowing bladder Stoppage of the upper urinary tract

surgical intervention. Consultation with a physician is particularly necessary in cases of blood in the urine or acute urine retention.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
Not applicable.

Effects on ability to drive and use machines
None known.

Undesirable effects
Gastrointestinal complaints [Djulepa 1982; Stahl 1984; Vontobel 1985; Kaldewey 1995; Engelmann 1996; Pagano 2014]. Rare cases of allergic skin reactions [Tosch 1983, Pagano 2014].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments
Significant suppression (average 67%) of SHBG binding capacity by a 10% solution of a 20% methanolic extract of nettle root has been demonstrated. It appears that the binding of 5α-dihydrotestosterone to proteins can be influenced by the extract [Schmidt 1983]. An aqueous extract of nettle root dose-dependently inhibited the binding of SHBG to solubilized receptors from human prostatic tissue; in the same experiment neither a 70% ethanolic extract of nettle root nor *Urtica dioica* agglutinin were effective [Hryb 1995].

The lignan secoisolariciresinol and a mixture of isomeric (11*E*)-9,10,13-trihydroxy-11-octadecenoic and (10*E*)-9,12,13-trihydroxy-10-octadecenoic acids isolated from nettle root reduced the binding activity of human SHBG; methylation of the mixed hydroxy acids increased their activity by about 10-fold [Ganßer 1995a].

(10*E*,12*Z*)-9-hydroxy-10,12-octadecadienoic acid isolated from an aqueous-methanolic extract of nettle root inhibited aromatase activity [Kraus1991b; Bartsch 1992]. On the other hand, aromatase inhibition by five other compounds isolated from a methanolic extract of nettle root was only weak (less than 1% compared to 4-hydroxy-androst-4-ene-3,17-dione) [Ganßer 1995b].

A polysaccharide fraction from an aqueous extract of nettle root showed activity in the lymphocyte transformation test. Isolated polysaccharides produced significant, concentration-dependent reduction of haemolysis (95% reduction at 1 mg/mL) in classical and alternative complement tests. From these results anti-inflammatory and immunomodulating activities were deduced [Wagner 1989; Willer 1990,1992]. Lectin fractions from *Urtica dioica* agglutinin stimulated the proliferation of human lymphocytes in the lymphocyte transformation test [Wagner 1989; Willer 1992].

Organic solvent extracts of nettle root inhibited Na^+, K^+-ATPase activity of human BPH tissue cells by 28-82% at 0.1 mg/mL. Steroidal compounds from nettle root, such as stigmast-4-en-3-one, stigmasterol and campesterol, inhibited the enzyme activity by 23.0-67.0% at concentrations from 10^{-3} to 10^{-6} M. These results suggest that some hydrophobic constituents such as steroids inhibit the membrane Na^+, K^+-ATPase activity of the prostate, which may subsequently suppress prostate-cell metabolism and growth [Hirano 1994].

A lectin fraction from *Urtica dioica* agglutinin inhibited by 53% the binding of epidermal growth factor (EGF) to EGF receptors in cells cultured from human prostatic tissue [Willer 1992]. The growth of cells cultured from human BPH tissue was significantly inhibited by 5 different fractions from a 20% methanolic extract of nettle root [Enderle-Schmidt 1988]. *Urtica dioica* agglutinin at 500 ng/mL to 100 µg/mL dose-dependently inhibited the binding of ^{125}I-labelled EGF to its receptor on human A431 epidermoid cancer cells [Wagner 1994].

Lignans present in polar extracts of nettle root, (+)-neo-olivil, (–)-secoisolariciresinol, dehydrodiconiferyl alcohol, isolariciresinol and (–)-3,4-divanillyltetrahydrofuran, as well as the main intestinal metabolites of plant lignans in humans (enterodiol, enterolactone and enterofuran), showed binding affinity to human SHBG. Outstandingly high affinity was exhibited by (–)-3,4-divanillyltetrahydrofuran, which is present only in traces in nettle root [Schöttner 1997b].

A 20% methanolic extract of nettle root significantly ($p<0.05$), and time- and concentration-dependently, inhibited the proliferation of human prostatic epithelial LNCaP (**l**ymph **n**ode **ca**rcinoma of the **p**rostate) cells; maximum growth reduction of 30% was obtained on day 5 at a concentration of 10^{-6} mg/mL. In contrast, the extract had no antiproliferative effect on human prostatic stromal cells. Comparable inhibition ($p<0.05$) of proliferation of human epithelial LNCaP cells by a polysaccharide-rich fraction (POLY M) of the same extract was observed over a 7-day period. Again, the inhibition was time- and concentration-dependent, with maximum suppression of 50% on day 6 at concentrations of 10^{-9} and 10^{-11} mg/mL. No cytotoxic effects of the extract or the fraction POLY-M on cell proliferation were observed [Lichius 1999a; Konrad 2000].

Nettle root extract inhibited cell proliferation in cultures of prostate tissue taken from BPH patients [Rausch 1992].

It has been shown that *Urtica dioica* agglutinin binds to the cell membrane of prostatic adenoma cells from BPH patients [Sinowatz 1994] and can inhibit the action of growth factors involved in the regulation of prostate growth [Wagner 1992].

An ethanolic and a petroleum ether extract inhibited 5α-reductase with an IC_{50} of 120 µg and 190 µg, respectively, compared to 1.06 µg by finasteride [Nahata 2012].

In vivo experiments

Ten dogs suffering from BPH, treated daily for 100 days with 90 mg/kg b.w. of a nettle root extract (3.5-7:1, 20% V/V methanol), showed an average decrease of 30% in prostate volume [Daube 1988]. The same extract did not inhibit testosterone and dihydrotestosterone stimulated growth of the prostate in castrated rats [Rhodes 1993].

A crude aqueous fraction from nettle root containing 4 different polysaccharides, administered orally at 40 mg/kg, significantly inhibited carrageenan-induced rat paw oedema by 36.8% after 5 hours ($p<0.01$) and 63.6% after 22 hours ($p<0.005$). This anti-inflammatory activity was comparable after 5 hours, and markedly superior after 22 hours, to that exhibited by indometacin at 10 mg/kg (42.1% and 27.3% inhibition respectively) [Wagner 1989, 1992, 1994c].

In a BPH model involving implantation of mouse fetal urogenital sinus tissue into the ventral prostate glands of adult male mice, a 20% methanolic extract of nettle root administered orally for 28 days reduced experimentally-induced prostate growth by 51.3%, compared to 26.5% by an aqueous extract [Lichius 1997]. In the same model, a polysaccharide-rich fraction (POLY-M) from the 20% methanolic extract reduced prostate growth by 33.8% whereas *Urtica dioica* agglutinin increased prostate growth by 20.1% and secoisolariciresinol by 37.2% [Lichius 1999b].

An ethanolic and a petroleum ether extract were administered orally to rats with testosterone-induced increased prostatic weight. At 50 mg/kg b.w. the nettle extracts reduced this weight increase by 70% and 73% respectively. At 10 mg/kg b.w the respective reductions were close to 30%, compared to 50% for β-Sitosterol at this level. The positive control finasteride at 1 mg/kg b.w reduced the weight increase by 80%. In the negative control group, administered only subcutaneous testosterone, urine output was reduced by 77% after 4 weeks. Treatment with the extracts reduced the urinary obstruction to 2 and 5%, β-Sitosterol to 11% and finasteride to 1% (at the above mentioned concentrations) [Nahata 2012].

Pharmacological studies in humans

31 men aged between 58 and 82 years with BPH at stages I to II were treated daily for 20 weeks with 1200 mg of a dried nettle root extract preparation (3.5-7:1; 20% V/V methanol). From fine needle aspiration biopsies of the prostate at 4-weekly intervals, morphologically significant changes in prostatic adenoma cells were detected that may relate to competitive inhibition of SHBG binding capacity by the extract [Ziegler 1982].

Prostatic cells taken by needle biopsy from 33 BPH patients treated with nettle root extract for about 6 months were investigated by fluorescence microscopy. Compared with normal prostatic cells, a decrease in homogenous granules was detected in hyperplastic cells from the BPH patients, indicating that biological activity in these cells had decreased [Ziegler 1983]. The presence of nettle root constituents or their metabolites in prostate tissue obtained (through prostatectomy) from BPH patients treated with nettle root extract was demonstrated by fluorescence microscopy. The granular fluorescence was not observed in prostate tissue from patients not treated with nettle root extract, but could be simulated to some extent by *in vitro* incubation of this tissue with nettle root extract [Dunzendorfer 1984].

Morphological examination of prostate tissue obtained by needle biopsy from BPH patients before and 6 months after therapy with nettle root extract confirmed ultrastructural changes in the smooth muscle cells and epithelial cells of the prostate [Oberholzer 1987].

Clinical studies

Clinical studies performed with dried native extract of nettle root (7-14:1, 20% V/V methanol) in a preparation containing an equal amount of diluent. As in the published reference papers where mg amounts are stated, ***the following dosages relate to the extract preparation, of which only 50% was native extract (7-14:1).***

A review of 34 clinical trials including 40,000 patients concluded that there is evidence of efficacy for the methanolic extract in

the improvement of BPH related complaints [Chrubasik 2007].

In a randomized, double-blind, placebo-controlled study with 40 BPH II patients (1200 mg of extract preparation per day, n = 20; placebo, n = 20), statistically significant ($p<0.05$) decreases in micturition frequency and SHBG levels were observed in the verum group after 6 months [Fischer 1992].

Significant improvements of 14% in average urinary flow rate and 40-53% in residual urine volume were observed in BPH patients (n = 32) who received 600 mg of extract preparation daily for 4-6 weeks in a randomized, placebo-controlled (n = 35), double-blind study [Dathe 1987].

Fifty BPH stage I-II patients enrolled in a double-blind, controlled study were treated daily for 9 weeks with 600 mg of extract preparation (n = 25) or placebo (n = 25). A significant increase of 44% in micturition volume ($p<0.05$) and a highly significant decrease in serum levels of SHBG ($p = 0.0005$) were observed. The latter effect was probably due to the SHBG binding capacity of the extract [Vontobel 1985].

In an open, multicentre study with 5492 patients receiving 600-1200 mg of extract preparation per day for 3-4 months, significant improvements in nycturia and daytime micturition frequency were observed [Tosch 1983]. A 50% decrease in nycturia was reported in an open, multicentre study with 4051 BPH patients who received 1200 mg of extract preparation per day for 10 weeks [29]. In another open, multicentre study, with 4480 BPH patients receiving 600-1200 mg of extract preparation per day for 20 weeks, significant improvements ($p<0.01$) in urinary flow and residual urine volume were observed [Friesen 1988].

111 BPH patients with nycturia received 1200 mg of extract preparation per day for 10 weeks in an open study. Nocturnal micturition frequency decreased in 55% of cases [Vandierendounck 1986]. 37 out of 39 BPH I-III patients experienced improvements in urinary flow, residual urine, nycturia and pollakisuria after a 6-month treatment with 600-1200 mg of extract preparation per day [Maar 1987]. In another open study, residual urine decreased in 67 out of 89 BPH patients receiving 600 mg of extract preparation per day for 3-24 months [Djulepa 1982].

Significant decreases ($p<0.05$) in prostate volume and residual urine volume as well as in serum SHBG, oestradiol and oestrone levels were observed in an open study with 253 BPH patients who received 1200 mg of extract preparation per day for 12 weeks [Bauer 1988]. Decreases in prostate volume in 54% of cases and residual urine in 75% of cases were observed in an open study with 26 BPH patients who received 1200 mg of extract preparation per day for 4-24 weeks [Feiber 1988].

A one-year double-blind, randomized, placebo-controlled, multicentre study involving 124 patients (mean age 64 ±0.6) treated with 459 mg nettle root dry extract once a day demonstrated a significant ($p=0.0233$) difference in decrease of the International Prostate Symptom Score (IPSS) in favour of the verum group, by 5.7 points (from 18.7 ±0.3 to 13.0 ±0.5) compared to 4.7 points (from 18.5 ±0.3 to 13.8 ±0.5) in the placebo group (122 patients; mean age 63). The secondary objective variables showed positive but non-significant results in favour of the verum group: maximal urinary flow was increased by 3mL/s while residual urinary volume was lowered by 5 mL, compared to 2.9 mL/s and 4 mL respectively for placebo. Analysis showed better results for quality of life improvement in the verum group (65%) than in the placebo group (62%) ($p=0.69$) [Schneider 2004].

Clinical studies performed with other nettle root preparations
In a double-blind, multicentre study, 41 BPH patients were treated daily for 3 months with either 2 x 3 mL of an aqueous extract preparation equivalent to 4.68 g of a fluid extract (1:1, 16% ethanol) (n = 20) or placebo (n = 21). A decrease in residual urinary volume of 19.2 mL in the verum group compared to 10.7 mL in the placebo group, and an increase in maximal urinary flow of 7.1 mL/s in the verum group compared to 4.4 mL/s in the placebo group, were observed. A significantly greater improvement ($p = 0.002$) in the IPSS was also reported in the verum group [Engelmann 1996].

Daily treatment for 60 days with 90-150 drops of a fluid extract (1:1, 45% ethanol; Ph. Fr.) led to a 66% decrease in residual urine in an open study with 10 BPH patients [Goetz 1989].

In an open study with 67 BPH patients, a reduction in nocturnal micturition frequency was observed after 6 months of daily treatment with 3 x 5 mL of a fluid extract (1:5, 40% ethanol) [Belaiche 1991].

In an open multicentre study involving 1319 patients with BPH and/or prostatitis, daily treatment for 6 months with 378-756 mg of a native extract of nettle root (12-16:1, 70% V/V ethanol) led to substantial improvements in dysuria, nycturia, pollakisuria, urinary flow and residual urine volume. 79.9% of the patients reported an improvement in their quality of life [Kaldewey 1995].

In a double blind, randomized, placebo-controlled, partial crossover study, 620 patients with lower urinary tract symptoms (LUTS) secondary to BPH, aged between 55 and 72 (mean age 63), were treated for 6 months with a preparation of *Urtica dioica* fluid extract (120 mg per dose; not further specified) (n = 305) or placebo (n = 315) three times daily with meals. Unblinding was carried out after completion of the six month trial, and for an 18 month follow-up period patients were allowed to continue with *Urtica dioica* treatment or to crossover if they had previously been on placebo. Patients with a follow up >16 months after participation in the trial were included in the analysis. After the initial 6 months, verum treatment demonstrated a significantly greater ($p<0.001$) reduction in residual urinary volume than placebo, from 73 mL ± 32.6 to 36 mL ± 25.5 in the verum group compared with 74 mL ± 29.6 to 71 mL ± 24.4 in the placebo group, and a significantly greater increase in maximal urinary flow ($p<0.05$) for verum (8.2 mL/s) compared to placebo (3.4 mL/s). Crossing over to *Urtica dioica* resulted in a reduction in urinary retention to a volume of 38 mL ± 25.5 and an increase of the maximal urinary flow by 7.4 mL/s. The size of the prostate was measured by transrectal ultrasonography (TRUS) and showed a significant reduction ($p<0.001$) of the prostate volume in the verum group from 40.1 cc ± 6.8 to 36.3cc ± 4.2, this increased again to 39.5 cc ± 6 in those patients who discontinued the medication during the follow up, while the volume stayed decreased in those patients who continued the medication during follow-up. There was also a significantly greater improvement to the IPSS in the verum group compared to placebo ($p<0.002$) [Safarinejad 2005].

In an open, prospective phase IV multicentre trial, 100 patients with LUTS received four capsules each containing 240 mg of a dry extract (5.4-6.6:1; ethanol 20% V/V) daily for 24 weeks. Treatment with the preparation resulted in a significant ($p<0.0001$) reduction in the IPSS from 19.5 ± 4.8 to 13 ± 5, a significant ($p<0.0001$) increase in the maximal urinary flow rate from 9.7 mL/s ± 2.2 to 13.2 mL/s ± 3.8 and a non-significant reduction of the residual urinary volume by 24.8 mL (±150). Digital measurement (n=48) showed no reduction in prostate volume after 24 weeks [Klein-Bischoff 2007].

Pharmacokinetic properties
After oral administration of 20 mg of purified *Urtica dioica* agglutinin (UDA) to patients and healthy volunteers, 30-50% was excreted unchanged in the faeces. The concentration in urine was in the 1-10 ng/mL range and the total amount of UDA in urine was less than 1% of the administered dose. These data confirmed the extreme stability of UDA in the digestive tract and its partial uptake and renal clearance [Samtleben 1996].

Preclinical safety data
No data available.

Clinical safety data
Over 16,000 patients were treated with nettle root extracts in clinical studies [Djulepa 1982; Tosch 1983; Stahl 1984; Vontobel 1985; Vandierendounck 1986; Dathe 1987; Maar 1987; Bauer 1988; Feiber 1988; Friesen 1988; Goetz 1989; Belaiche 1991; Fischer 1992; Kaldewey 1995; Engelmann 1996] and have taken daily doses of up to 756 mg of hydroalcoholic dry native extract for periods of up to 6 months or, in a few cases, 300 mg of dry native extract for 24 months. The incidence of adverse events was generally under 5%. No serious adverse effects have been reported, the majority of complaints being mild gastrointestinal upsets. In a large open study involving 1319 patients, the incidence of adverse events probably or possibly related to treatment with nettle root extract was 1.0% [Kaldewey 1995].

According to a review, the majority of 40,000 patients participating in clinical trials were treated with an extract prepared with 20% methanol. As adverse effects were only reported as occurring in 2% of all cases, and these were of minor concern, treatment with this particular extract was suggested to be safe [Chrubasik 2007].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

UVAE URSI FOLIUM

2012

Bearberry Leaf

DEFINITION

Bearberry leaf consists of the whole or cut dried leaf of *Arctostaphylos uva-ursi* (L.) Spreng. It contains not less than 7.0% of anhydrous arbutin ($C_{12}H_{16}O_7$; M_r 272.3), calculated with reference to the dried drug.

The material complies with the monograph of the European Pharmacopoeia [Bearberry Leaf].

CONSTITUENTS

The main characteristic constituent of bearberry leaf is arbutin (5 to 15%) accompanied by variable amounts of methylarbutin (up to 4%) and by small amounts of the free aglycones hydroquinone (less than 0.3%) and methylhydroquinone [Sticher 1979; Linnenbrink 1984;Veit 1992; Blaschek 2007]. Other constituents include gallic acid, galloylarbutin and up to 20% of gallotannins [Hegnauer 1989]; flavonoids, especially glycosides of quercetin, kaempferol and myricetin [Hegnauer 1989; Blaschek 2007]; and 0.4 to 0.75% triterpenes, mainly ursolic acid and uvaol [Hegnauer 1989; Blaschek 2007].

CLINICAL PARTICULARS

Therapeutic indications

Uncomplicated infections of the lower urinary tract [Frohne 1970; Kedzia 1975; Bradley 1992; Wichtl 1999; Fintelmann 2009; Blaschek 2009; Schilcher 2010] such as cystitis, when antibiotic treatment is not considered essential [Coe 1989; Furrer 1994; Weber 1995].

Posology and method of administration

Dosage

Adults: Cold water macerates of 9 to 12 g dried leaf corresponding to 400-800 mg of arbutin per day, divided into 2-4 doses; equivalent preparations [Blaschek 2009; Schilcher 2010].

Not recommended for children below 12 years [Blaschek 2007; Schilcher 2010].

Method of administration
For oral administration. Patients should be advised to consume plenty of liquid during the treatment [Fintelmann 2009].

Duration of administration
Treatment should be continued until complete disappearance of symptoms (up to a maximum of 1 week) [Schilcher 2010].

Contraindications
Pregnancy, lactation, children below 12 years of age [Schilcher 2010].

Special warnings and special precautions for use
If symptoms worsen after 48 hours medical advice should be sought.

Interaction with other medicaments and other forms of interaction
None reported in clinical studies.

Pregnancy and lactation
Bearberry leaf should not be used during pregnancy or lactation [Mills 2005].

Effects on ability to drive and use machines
None known.

Undesirable effects
Nausea and vomiting may occur due to stomach irritation from the high tannin

E/S/C/O/P MONOGRAPHS

content of bearberry leaf [Blaschek 2009].

Overdose
No reports are available on overdose of bearberry leaf.

PHARMACOLOGICAL PROPERTIES

The ability of bearberry leaf to resolve uncomplicated infections of the lower urinary tract is based on its antibacterial and anti-inflammatory properties. Although the exact mechanisms are not fully elucidated the pharmacodynamic and pharmacokinetic data suggest that most of the effect is mediated by arbutin [Jahodar 1985a; Moskalenko 1986; Holopainen 1988; Rios 1987; Paper 1993].

Pharmacodynamic properties

In vitro experiments

Antimicrobial activity
The antimicrobial activity of a 70% ethanolic bearberry leaf extract (1:5) was tested using the disc assay. The extract demonstrated maximal antibacterial activity against *Staphylococcus aureus*, *Bacillus subtilis*, and *Mycobacterium smegmatis* [Moskalenko 1986].

The antimicrobial activity of an 80% ethanolic whole plant extract was tested against *Escherichia coli*, *Proteus vulgaris*, *Streptococcus faecalis*, *Enterobacter aerogenes* and compared to streptomycin. The greatest activities were found against *E. coli* (approx. 1/100 of the activity of streptomycin) and *P. vulgaris* (approx. 1/300) [Holopainen 1988].

A 95% ethanolic bearberry leaf extract showed antibacterial activity against *Staphylococcus aureus* (MIC 2 g/L) [Rios 1987].

The effect of arbutin on different bacteria was related to their extracellular ß-glucosidase activity. The highest ß-glucosidase activity was found in *Streptococcus faecalis* (100%), *Proteus vulgaris* (100%), *Klebsiellae* (95%) and *Enterobacteriae* (72%), and the lowest in *E. coli* (11.6%). A 90 to 100% bactericidal effect was achieved for the species *Klebsiella pneumoniae* and *S. faecalis* at 4 µg/ml and for *Enterobacter cloacae* and *P. vulgaris* at 5.6µg/ml [Jahodář 1985a].

Older experiments revealed strong antibacterial properties of urine samples obtained from healthy volunteers after consumption of arbutin or bearberry tea. This effect was only observed with urine adjusted to pH 8, whilst urine of pH 6 was ineffective [Frohne 1970; Kedzia 1975].

Urine samples of volunteers, after ingestion of a 60% ethanolic extract (corresponding to 420 mg arbutin), were incubated with *E. coli* which was able to deconjugate the hydroquinone (HQ) glucuronide and sulphate to free HQ [Siegers 1997]. Further investigations demonstrated that the majority of the free HQ was found inside the bacteria, this way exerting the antibacterial effect [Siegers 2003]. Accordingly, the pH of urine neither modifies HQ formation nor the antibacterial effect of HQ derivatives [Garcia 2010].

Anti-inflammatory activity
Preincubation of rat peritoneal mast cells with a methanolic bearberry leaf extract at 20, 100 and 500 µg/ml reduced histamine release to 88%, 65.1% and 23.6%, respectively [Kubo 1990].

The ability of a bearberry leaf extract to prevent LPS-induced up-regulation of NO production was examined on N-11 murine microglia and in RAW 264.7 murine macrophages. The extract at concentrations between 5 and 50 µg/ml, corresponding to 3 to 30 nM arbutin, significantly reduced LPS-induced NO production with an IC_{50} value of around 20 µg/mL [Shanmugam 2008].

Arbutin was shown to decrease the neutrophil oxidative burst dose-dependently, starting at concentrations of 1µM. A more detailed study on isolated human neutrophils showed that arbutin potently decreased the external oxidant concentration without reduction of the oxidative burst arising inside neutrophils [Jančinová 2007].

Anti-adherence activity
An aqueous extract of bearberry leaf enhanced the surface hydrophobicity of 40 *E. coli* and 20 *Acinetobacter baumannii* strains and increased the cell aggregation capacity [Türi 1997].

An aqueous extract decreased the surface hydrophobicity of *Helicobacter pylori* and enhanced the cell aggregation capacity in the salt aggregation test [Annuk 1999].

Other activities
A bearberry leaf extract (not further specified; 10 µg/ml) showed antioxidant activity in U937 cells and strongly protected cells against DNA damage induced by hydrogen peroxide and *t*-butanol [Carpenter 2006].

Aqueous and methanolic extracts of five commercial bearberry leaf preparations demonstrated *in vitro* inhibition of cytochrome P450 isoenzymes [Chauhan 2007].

In vivo experiments

Anti-inflammatory activity
A 50% methanolic bearberry leaf extract was administered *p.o.* to mice at doses of 20, 100 and 500 mg/kg b.w. immediately before and 16 hours after picryl chloride application. The extract did not show a relevant inhibitory effect on ear swelling when compared to prednisolone. However, the effect of prednisolone was enhanced by combination with bearberry leaf. In the same experiment, arbutin had a significant effect only at an oral dose of 50 mg/kg in combination with prednisolone ($p<0.01$) [Kubo 1990]. Oral administration of 20, 100 or 500 mg/kg of the bearberry leaf extract reduced acetic acid-induced capillary vascular permeability in mice by 10.4, 21.7 and 27.9% respectively. A significant effect ($p<0.05$) was observed only for the highest dose [Kubo 1990]. The extract significantly reduced carrageenin-induced paw oedema in Wistar rats at an oral dose of 100 and 500 mg/kg, the effect being significant for the highest dose ($p<0.05$) [Kubo 1990)].

Oral administration of arbutin at 50 mg/kg/day for 28 days was shown to decrease plasma levels of the pro-inflammatory cytokine IL-6 in a rat model of adjuvant arthritis. The control plasma level of interleukin-6 was 29.4±2.6 pg/ml and was increased on days 14 and 21 of arthritis to 119.9±14.3 and 101.3±11.3 pg/ml, respectively. In the group treated with arbutin, the respective IL-6 concentrations were 72.8±12.0 and 35.5±8.8 pg/ml. In addition, arbutin was found to inhibit neutrophil activity in the experimental arthritis model [Jančinová 2007].

Diuretic activity
An aqueous extract of bearberry leaf was administered *i.p.* to 10 male rats as a single dose of 50 mg/kg b.w.; a control group of 10 rats received hypotonic saline solution and another group of 10 rats received hydrochlorothiazide at 10 mg/kg. The urine volume from rats treated with the extract was higher than from the controls and was comparable to the volume after

hydrochlorothiazide [Beaux 1999].

Female Wistar rats received a bearberry leaf extract (prepared from 3 g of the drug/L) ad libitum instead of tap water, with a diet fortified with calcium (8 g/kg b.w.) for 12 days. After that period, two 24-hour urine samples were collected. Excretion of calcium, citrate, phosphate, creatinine, pH and diuresis were evaluated in control and treated rats. No relevant differences between control and treated rats were observed in any of the parameters [Grases 1994].

Pharmacokinetic properties

Arbutin, the main active constituent of bearberry leaf, is rapidly absorbed after oral administration of the pure substance or bearberry leaf tea or bearberry leaf extract preparations via a Na^+/glucose carrier [Paper 1993; Schindler 2002; Quintus 2005; Blaut 2006].

In vitro and human studies have demonstrated that arbutin does not undergo hydrolysis in the stomach and reaches the small intestine intact. The contribution of bacteria to arbutin hydrolysis in the small intestine is very small [Paper 1993; Blaut 2006].

In rats, arbutin is eliminated unchanged, while in humans arbutin is eliminated in the form of conjugated metabolites. Urinary excretion of free HQ (less than 0.6% of the administered dose) and arbutin metabolites (HQ-glucuronide and HQ-sulphate) occurs within a few hours, with maximum excretion during the first 6 hours; within 24 hours approximately 70-100% of the administered dose is excreted [Frohne 1970; Kedzia 1975; Paper 1993; Siegers 1997; Schindler 2002; Quintus 2005; Blaut 2006].

Older *in vitro* experiments suggest the uptake of arbutin and a lack of free HQ in biopsy homogenates from the small intestine of rat, hamster and chicken as well as in human small intestine of healthy volunteers [Garcia et al. 2010].

An *in vivo* study with Fischer 344 rats investigated the tissue distribution of ^{14}C-hydroquinone (^{14}C-HQ; 25 or 50 mg/kg b.w.) following single or repeated oral administration. After a single dose, HQ was rapidly absorbed, metabolized and eliminated as conjugated HQ. Free HQ eliminated in the urine represented less than 1% of the total administered dose. The mean radioactivity recovered in the combined tissues and carcasses ranged from 0.51% to 0.96% of the dose. Livers and kidneys contained the highest concentrations of ^{14}C-HQ (0.24% and 0.04%, respectively). In a repeated dose study, 8 rats were treated daily for 14 days with unlabeled HQ (25 mg/kg) and with ^{14}C-HQ on day 15. Blood concentration increased to a plateau in the first 30 min and declined to the limits of quantification by 24 h after dose administration. A mean of 87-94% of the dose was recovered in the urine and an additional 1-3% of the dose was recovered in the faeces [English 2005].

The elimination of arbutin (20, 100 and 400 mg/kg) was investigated in female Wistar rats. Up to 16 hours after oral administration nearly 82% of the arbutin was eliminated unchanged, even after changing urine pH; and excretion was complete after 30 hours. Free HQ as a possible degradation product was not detected [Jahodář 1985b].

In a study on the metabolism of arbutin following oral intake of bearberry leaf, twelve healthy volunteers received 3 x 2 coated tablets containing a 60% ethanolic extract of bearberry leaf (corresponding to 420 mg arbutin). Only 0.6% of the arbutin was excreted as free HQ, whereas 70% (294 mg) was detected as HQ-conjugates to glucuronic and sulphuric acid in the urine. In 6 volunteers no free HQ was detected [Siegers 1997].

In a preliminary pharmacokinetic study in 3 volunteers, the time-dependent renal excretion of arbutin metabolites HQ-glucuronide, free HQ and HQ-sulphate was investigated after ingestion of an aqueous bearberry leaf extract containing 150 mg of arbutin. More than 50% of the arbutin was excreted within 4 hours, mainly in the form of the metabolites HQ-glucuronide and HQ-sulphate; and more than 75% of the total administered arbutin was excreted within 24 hours. The elimination of free HQ was negligible in 2 out of 3 volunteers, and only in the third reached 5.6% of the total administered arbutin dose [Quintus 2005].

A cross-over study in 6 healthy volunteers investigated the bioavailability of an aqueous preparation of bearberry leaf compared to that of enteric-coated tablets containing the same herbal substance. The mean arbutin content in one enteric-coated tablet corresponding to 250 mg bearberry leaf was 50 mg. The aqueous extract was prepared to contain the same amount of arbutin. The participants received 2 tablets or 500 mg of the aqueous preparation. Five urine samples were collected within 24 hours. After a washout phase of 24 hours the volunteers received a single dose of the other preparation. The mean total amount of arbutin detected after 24 hours in urine of subjects treated with the aqueous preparation was 86.6 ± 16.3 mg. In urine from subjects treated with coated tablets, the total amount of arbutin was 82.8 ± 16.1 mg. Therefore, a very high percentage of arbutin was recovered in the urine for both herbal preparations after 24 hours. No free HQ was detected and differences in the pH of the urines (6.5 to 8) had no influence on the amount of free HQ. After administration of the aqueous extract, most of the arbutin was eliminated within 3 hours (53% of the total arbutin), whereas with the coated tablets maximum arbutin elimination was found after 3 to 6 hours (31% of the total arbutin) [Paper 1993].

An open, randomized, crossover study with 16 healthy volunteers compared the bioavailability of a single oral dose of bearberry leaf dry extract as film-coated tablets or as a herbal tea. Participants received either 2 tablets containing 472.5 mg of bearberry leaf dry extract (corresponding to 105 mg arbutin each) or 100 ml of an aqueous herbal preparation containing 945.0 mg of bearberry leaf dry extract (corresponding to 210 mg arbutin). Urine was collected 90 min prior to the experiment and during the periods 0 to 4, 4 to 8, 8 to 12, 12 to 24 and 24 to 36 hours after drug administration. The three major metabolites identified in urine were free HQ, HQ-glucuronide and HQ-sulphate. After administration of the film-coated tablets 66.7 % of the arbutin was excreted in the urine and after the aqueous herbal preparation 64.8%. The major metabolite HQ-glucuronide accounted for 67.3% and 70.3% after coated tablet or herbal tea administration, respectively. Both metabolites were rapidly excreted mainly during the first 4 hours for both preparations. No further excretion of arbutin metabolites was detected in urine more than 24 hours after extract administration. The mean amounts of free HQ and each HQ metabolite in urine did not differ significantly between the two preparations. The relative availability of arbutin from the tablets, in relation to the aqueous herbal preparation, was 103.3% based on the relative urinary excretion of the arbutin metabolites (total HQ, free HQ, HQ-glucuronide and HQ-sulphate) [Schindler 2002].

Preclinical safety data

Single dose toxicity
No data have been reported for bearberry leaf. No toxic effects were observed in mice treated with arbutin at 50-200 mg/kg b.w., *p.o.* or *i.p.* [NTP 2006].

The oral LD_{50} value of hydroquinone was greater than 375

mg/kg in male and female Sprague-Dawley rats [Topping 2007], 400 mg/kg in mice, 550 mg/kg in guinea pigs, 300 mg/kg in pigeons, 70 mg/kg in cats and 200 mg/kg in dogs [Woodard 1949]. The high sensitivity of cats is related to lower glucuronide conjugation activity in the liver and intestinal tract. Administration in the food decreased the rate and extent of HQ absorption, thus increasing oral LD_{50} values up to 1050 mg/kg in rats [DeCaprio 1999].

LD_{50} values for HQ by parenteral administration have been reported as 115-160 mg/kg in the rat and 190 mg/kg in the mouse [DeCaprio 1999].

Dermal application of 200 mg /kg of HQ to rabbits under occlusive wrap for 24 hours did not result in neurobehavioural effects or mortality [Topping 2007].

Repeated dose toxicity
No data have been reported for bearberry leaf.

Arbutin administered intraperitoneally to mice, at a dose of 8 g/kg b.w. for a period of 2 weeks, did not induce toxic effects [NTP 2006].

Subchronic exposure of male and female Sprague-Dawley rats to free HQ (200, 64, 20 mg/kg b.w./day) revealed that doses up to 64 mg/kg HQ resulted in acute behavioural effects including tremors and reduced activity. Tremors occurred within 1 hour of dosing and resolved at hour 6. Brain weights were not altered by HQ administration, but mean terminal body weight was reduced by approximately 7% after doses of 200 mg/kg in males. No treatment-related morphological or histological changes of organs were observed. Neuropathologic examination of the CNS and PNS did not reveal any morphologic lesions associated with HQ administration or due to repetitive CNS stimulation by HQ. No nephrotoxic effects were observed in rats given 200 mg/kg [Topping 2007].

Two toxicity studies with free HQ were conducted in F344 rats and B6C3F mice for 2 and 13 weeks and the animals were treated 5 days/week. Mice received 0, 31, 63, 125, 250 or 500 mg HQ/kg b.w. in corn oil by gavage for 14 days. Rats received 0, 63, 125, 250, 500 or 1000 mg HQ/kg b.w. on the same schedule. No chronic toxicity was observed at doses below LD_{50} for rats and mice, which range from 200 to 500 mg/kg (NTP 1989). In mice, 4/5 males and 5/5 females at the dose of 500 mg/kg and 3/5 males at 250 mg/kg died before the end of the study. Tremors followed by convulsions were seen at doses of 250 and 500 mg/kg. All rats receiving a dose of 1000 mg/kg as well as 1/5 male rats and 4/5 female rats at the 500 mg/kg dose died before the end of the study. Clinical signs included tremors lasting up to 30 min after each dosing of 500 and 1000 mg/kg [NTP 1989; Kari 1992].

In a 13-week study, mice and rats received 0, 25, 50, 100, 200 or 400 mg free HQ/kg b.w. administered in corn oil by gavage. Doses below LD_{50} did not show any signs of toxicity. Free HQ at 400 mg/kg caused death in all rats and 3/10 female rats had already died before the end of the study at 200 mg/kg. Tremors and convulsions were observed in most rats receiving 400 mg/kg and in several female rats receiving 200 mg/kg. Inflammation and/or epithelial hyperplasia of the fore-stomach were seen in 4/10 male rats and 1/10 female rats receiving 200 mg/kg. Toxic nephropathy, characterized by tubular cell degeneration in the renal cortex, was seen in 7/10 male and 6/10 female rats receiving 200 mg/kg and in 1/10 females receiving 100 mg/kg. [NTP 1989; Kari 1992].

In a long-term repeated-dose toxicity study, mice were given 0, 50 or 100 mg HQ/kg b.w. for up to 2 years. Rats received 0, 25 or 50 mg HQ/kg b.w. on the same schedule. At the highest dose, the mean body weights in mice and rats were approximately 5 to 14% lower than those of controls. No significant differences in survival were observed between treated and control animals. In male rats receiving 50 mg/kg HQ a significantly higher severity of nephropathy ($p<0.01$) and compound-related lesions in the liver including anisokaryosis, syncytial alteration and basophilic foci were observed [Kari 1992]. Mononuclear cell leukaemia in female rats occurred with an increased incidence in the dosed groups (vehicle control, 9/55; low dose, 15/55; high dose, 22/55) [NTP 1989].

Earlier studies showed that in the rat kidney the outer stripe of the outer medulla, particularly in renal proximal tubules, were mainly affected by the toxicity of HQ. In re-evaluations [Hard 1997; Whysner 1995] these results were interpreted as an exacerbation of a spontaneous, age-related disease occurring primarily in male rats (chronic progressive nephropathy), with no known counterpart in humans [IARC 1999; McGregor 2007; NTP, 2009].

Reproductive toxicity
No data have been reported for bearberry leaf.

A study in 240 Sprague-Dawley rats evaluated the effects of arbutin on the reproductive performance of the parent rats as well as on the development and reproductive performance of the offspring. Arbutin was administered s.c. at doses of 25, 100 or 400 mg/kg b.w. daily to male rats before mating and to female rats during pregnancy and lactation. All pregnant parent rats delivered with normality. No effect on reproduction of male and female rats or the development of the offspring was observed at doses up to 100 mg/kg. No treatment-related change in the reproductive performance of the F1 rats was observed. Foetal toxicity occurred at doses of 400 mg/kg[Itabashi 1988].

Genotoxicity and Mutagenicity
Bearberry leaf has been shown to be non-mutagenic in the Ames test using *Salmonella typhimurium* strains TA98 and TA100, and in the *Bacillus subtilis* rec-assay [Morimoto 1982]. In the cytochalasin block micronucleus test a 70% ethanolic bearberry leaf extract (0.025 - 0.2 mg/ml) did not show clastogenic activity as it did not affect the yield of micronuclei either in irradiated or unirradiated human blood lymphocytes [Jokic 2003].

An *in vitro* study investigated the mutagenic capacity of arbutin (0.1-10 µM) in mammalian cells after deglycosylation to free HQ by human intestinal bacteria. Mutagenicity was detected by the determination of mutant frequency in Chinese hamster V79 cells.

Four of nine representative human intestinal species investigated, namely *Eubacterium ramulus*, *Enterococcus casseliflavus*, *Bacteroides distasonis* and *Bifidobacterium adolescentis*, deglycosylated arbutin at rates of 21.08, 16.62, 8.43 and 3.59 nmol x min^{-1}/mg protein, respectively. In contrast, homogenates from small intestinal mucosa and cytosolic fractions from colon mucosa deglycosylated arbutin at substantially lower rates: 0.50 and 0.09 nmol x min^{-1}/mg protein, respectively. Arbutin, unlike HQ, did not induce gene mutations in Chinese hamster V79 cells in the absence of an activating system. However, in the presence of cytosolic fractions from *E. ramulus* or *B. distasonis*, arbutin (1mM) was strongly mutagenic. Cytosolic fraction from *Escherichia coli*, showing no arbutin glycosidase activity, was not able to activate arbutin in this model system [Blaut 2006]. Hydroquinone was found to be mildly myeloclastogenic in the micronucleus test in SPF mice after oral administration of

a toxic dose (200 mg/kg b.w.) [Gad-el-Karim 1985].

Urine samples from 12 volunteers after oral intake of a preparation corresponding to 420 mg arbutin/day did not show mutagenic potential *in vitro* in the Ames test with typical bacterial strains. Neither was any mutagenic potential found in vivo in the micronucleus assay in mice [Siegers 1997].

Carcinogenicity
No data have been reported for bearberry leaf.

Clinical safety data

An observational case report assumed that ingestion of an unspecified bearberry leaf preparation for three years at an unspecified dose caused bilateral bull's-eye maculopathy in a 56-year-old woman [Wang 2004].

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

Plant illustrated on the cover: *Vaccinium macrocarpon*

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

VACCINII MACROCARPI FRUCTUS 2020

Cranberry

DEFINITIONS

Cranberry
Cranberry consists of the ripe, fresh or dried fruits of *Vaccinium macrocarpon* Aiton.

Cranberry Liquid Preparation
Cranberry liquid preparation is a bright red juice derived from the fruits of *Vaccinium macrocarpon* Aiton or *Vaccinium oxycoccus* L. It contains no added substances.

The material complies with the monograph of the United States Pharmacopeia [Cranberry liquid preparation].

CONSTITUENTS

Cranberry
The main characteristic constituents of cranberry are A-type proanthocyanidins [Foo 2000a,b] and lower amounts of B-type proanthocyanidins [Feliciano 2013]; quinic, malic and citric acids (2.6-3.6%) [Jensen 2002, Coppola 1986]; benzoic acid (up to 0.5%), hydroxybenzoic acids and hydroxycinnamic acids, mainly in bound forms [Marwan 1982, Chen 2001, Zuo 2002, Murphy 2003, He 2006]; anthocyanins, especially peonidin 3-arabinoside and 3-galactoside [Hong 1986, Ohnishi 2006, Neto 2007, Kylli 2011]; flavonol glycosides, mainly of quercetin and myricetin [Yan 2002, Vvedenskaya 2004, Neto 2007]; iridoids (monotropein and 6,7-dihydromonotropein) [Jensen 2002]; ursolic acid and derivatives [Schmandke 2004, He 2006]; fructose, xyloglucans and other sugars [Hong 1986, Hotchkiss 2015] and volatile compounds [Zhu 2001].

Cranberry Liquid Preparation
The content requirements of the United States Pharmacopeia include: not less than 2.4% of dextrose, 0.7% of fructose, 0.9% of quinic acid, 0.9% of citric acid and 0.7% of malic acid; a quinic acid to malic acid ratio of not less than 1.0; and not more than 0.05% each of sorbitol and sucrose [Cranberry liquid preparation].

CLINICAL PARTICULARS

Therapeutic indications
Prevention of urinary tract infections (UTIs) [Ferrara 2009, Takahashi 2013, Foxman 2015, Maki 2016].

Posology and method of administration

Dosage

Adults: 240-750 mL per day of a cranberry liquid preparation containing 25-100% of cranberry juice, divided into 2 or 3 portions; 200-500 mg of cranberry dry extract or juice concentrate twice daily [Avorn 1994, Walker 1997, Stothers 2002, Hess 2008, McMurdo 2009, Maki 2016, Vostolova 2015]; other equivalent preparations [Foxman 2015].

Children 2-18 years of age: 2-15 mL of cranberry juice per kg body weight [Foda 1995, Afshar 2012, Salo 2012]; other equivalent preparations [Fernández-Puentes 2015]

Note: The liquid and solid cranberry preparations that have been used in clinical studies are mainly commercial products, variously and often inadequately described as cranberry juice, cranberry juice cocktail, cranberry concentrated juice, cranberry concentrate, cranberry extract, cranberry concentrated extract etc. The heterogeneity of products and dosages used make it difficult to define a minimum or optimal dosage and composition for effective cranberry preparations [Jepson 2008, Nowack 2008, Guay 2009].

E/S/C/O/P
MONOGRAPHS

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contra-indications
None known.

Special warnings and special precautions for use
Increased medical supervision and international normalized ratio (INR) monitoring should be considered for any patient on warfarin and taking high amounts of cranberry juice regularly [UK Medicines and Healthcare Products Regulatory Agency 2004, Ansell 2009].
Patients with a history of calcium oxalate nephrolithiasis should seek medical advice before intake of cranberry.

Interaction with other medicaments and other forms of interaction
A pharmacokinetic interaction between cranberry juice and warfarin is unlikely, especially with moderate cranberry consumption [Greenblatt 2006a,b, Li 2006, Lilja 2007, Ansell 2008, Zikria 2010].

Pregnancy and lactation
Except under medical supervision, cranberry should not be taken during pregnancy or lactation in amounts greatly exceeding those found in foods [Barnes 2007].

Effects on ability to drive and use machines
None known.

Undesirable effects
None of clinical relevance reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Anti-adherence activity
Cranberry juice inhibited by more than 75% the adherence to uroepithelial cells of more than 60% of isolates of *Escherichia coli* from clinical samples (out of 77 isolates tested) [Sobota 1984].

Inhibitory effects of cranberry juice on the adherence to eukaryotic cells of various *E. coli* strains were investigated in several models. The inhibitory activity against type 1 fimbriated *E. coli* was ascribed to the fructose content of cranberry juice. Inhibitory activity against P-fimbriated bacteria was non-dialyzable, suggesting that high molecular weight constituents are involved [Zafriri 1989].

Electron micrographic evidence from P-fimbriae-producing strains of *E. coli* grown in media with a cranberry juice content of 25% suggested that the juice acts on the cell wall, preventing the proper attachment of fimbrial subunits, or as a genetic control preventing the expression of normal fimbrial subunits, or both [Ahuja 1998].

Atomic force microscopy was used to investigate bacterial surface characteristics and adhesion forces between a silicon nitride probe surface and two strains of *E. coli*, one P-fimbriated and the other non-fimbriate, after exposure to dilutions of a cranberry juice neutralized to pH 7. The results demonstrated molecular-level changes on the surfaces of P-fimbriated *E. coli* upon exposure to neutralized cranberry juice [Liu 2006].

Presence of 10% juice or the equivalent amount of a proanthocyanidin (PAC)-enriched fraction during cultivation of *E. coli* resulted in the downregulation of flagellar basal body rod and motor proteins as shown in gene expression analysis. In SEM images a decrease in the visible P-fimbriae was observed [Johnson 2008].

P-fimbriated *E. coli* can form strong bonds with the Gal-Gal disaccharide receptor on uroepithelial cells, while non-fimbriated *E. coli* interactions are only non-specific. In the P-fimbriated *E. coli*-uroepithelial cell system, Gibbs free energy of adhesion values increased as a function of increasing cranberry juice concentration up to the point where adhesion became unfavourable. The results suggested that cranberry juice may disrupt bacterial ligand-uroepithelial cell receptor binding, thus inhibiting bacterial attachment to the host tissue [Liu 2008].

Atomic force microscopy resulted in a significant decrease in adhesion forces to a model surface when *E. coli* (non-fimbriated HB101 or P-fimbriated HB101pDC1) was cultivated under addition of either light cranberry juice cocktail (L-CJC) or PACs ($p<0.001$). Exposure of *E. coli* HB101pDC1 to increasing concentrations of L-CJC or PACs decreased bacterial attachment to human ureteral epithelial cells (CRL 9520 VA) ($p<0.001$) [Pinzon-Arango 2009].

P-fimbriated *E. coli* HB101pDC1 or non-fimbriated *E. coli* HB101 were attached to atomic force microscopy tips, and the adhesion forces between *E. coli* and uroepithelial cells in solutions containing 0, 2.5, 5, 10 and 27% cranberry juice were measured. The adhesion forces between *E. coli* HB101pDC1 and uroepithelial cells decreased dose-dependently [Liu 2010].

Adherence of *P. aeruginosa* PAO1 to uroepithelial cells decreased significantly ($p<0.001$) in the presence of cranberry juice as compared to control. Biofilm formation on sterile catheters was significantly ($p<0.001$) reduced with substantially less exopolysaccharides in the biofilms. With the juice, lower levels of alginate, cell surface hydrophobicity, pyochelin, haemolysin and phospholipase C were also observed in the culture supernatant of the biofilm cells [Harjai 2014].

In tests of cranberry juice extract and fractions thereof, surface adhesion of the antibiotic-resistant pathogenic *E. coli* B78 and the non-pathogenic strain *E. coli* HB101 to silicon nitride tips was determined by atomic force microscopy (AFM). The extract and three flavonoid-rich fractions did not change the adhesion of *E. coli* HB101. In contrast, a significant ($p<0.001$) decrease in the adhesion forces of strain B78 was shown, as compared to control [Gupta 2016].

Freeze-dried cranberry powder (9 mg PAC/g) reduced the mean adherence of a P-fimbriated uropathogenic *E. coli* isolate to vaginal epithelial cells from 18.6 to 1.8 bacteria per cell ($p<0.001$). At 50 µg/mL a purified PAC extract from fresh cranberry reduced mean adherence of this strain to primary cultured bladder epithelial cells from 6.9 to 1.6 bacteria per cell ($p<0.001$) in a linear and dose-dependent manner [Gupta 2007].

In uropathogenic *E. coli* strain CFT073 exposed to dried cranberry powder (CP; 5, 10, and 20 mg/mL) or PACs (0.1 mg/mL), expression of the flagellin gene involved in flagella formation, and motility was inhibited. Transmission electron

microscopy imaging revealed fewer flagella in bacteria grown with CP or PACs. Swimming and swarming motilities were hindered significantly ($p< 0.001$ for CP at 10, 15, 20 mg/mL and for CP at 5, 10, 15, 20 mg/mL, as well as PACs at 0.1 mg/mL, respectively) [Hidalgo 2011].

An extract enriched in PACs at concentrations of 5, 25, 75 and 137 mg PACs/mL demonstrated a dose-dependent inhibition of adherence of *E. coli* to human urinary bladder carcinoma T24 cells by 17%, 52%, 76 and 89% respectively [Risco-Rodríguez 2015]. Urine samples from rats taking this preparation as powder for oral suspension or as tablets (118 mg PACs/animal) showed an inhibition of *E. coli* adherence to bladder epithelial cells of 83% and 52% respectively. The lower dose of 59 mg PACs/animal also resulted in an inhibition of adherence (40% and 29% respectively) [Risco 2010].

In an adhesion/invasion assay a dry PAC extract significantly ($p<0.01$) reduced invasion of canine kidney cells by pathogenic *E. coli* CFT073 and O157:H7, *Enterococcus faecalis* 29212, and *Pseudomonas aeruginosa* 10145. Adhesion of Gram-positive *E. faecalis* decreased upon treatment, whereas adhesion of the Gram-negative strains slightly increased [Tukenkji 2010].

Two dry extracts, standardized for PACs, at concentrations of 5 -180 µg/mL significantly ($p<0.05$) inhibited adhesion of an *E. coli* strain carrying PAOGII fimbriae to uroepithelial cells. Another extract showed significant inhibition ($p<0.05$) only from 20 µg/mL upwards [Ermel 2012].

Adherence to uroepithelial cells of *E. coli* strains 8 and 269 was concentration-dependently reduced by an extract (not further specified). After exposure to 0.75×MIC of the extract (38 and 55 mg/mL respectively), the percentage of adherent bacteria was 18.4% and 22.9% for *E. coli* strains 8 and 269 respectively, as compared to control [Wojnicz 2012].

An extract significantly ($p<0.05$) inhibited the adhesion to polystyrene surfaces of *Candida albicans* ATCC 3153 at concentrations of 10, 20 and 40 mg/mL and of *C. glabrata* IHEM9556 at the two higher concentrations. Pretreatment of surfaces with the extract induced an anti-adhesion activity mainly against the different strains of *C. glabrata* and an anti-biofilm activity against various strains of *C. albicans* [Girardot 2014].

In contrast, a dose-dependent increase in bacterial adhesion of two *E. coli* strains to T24 bladder cells was observed with a cranberry extract with 21% PACs from 10 to 100 µg/mL ($p<0.05$ and 0.01 respectively). Confocal laser scanning microscopy and scanning electron microscopy proved that the extract led to the formation of bacterial clusters on the outer plasma membrane of the host cells without subsequent internalization. This activity was not observed with a PAC-depleted extract. The latter extract showed significant inhibition of adhesion of type 1 fimbriae dominated and mannose-sensitive strain NU14 ($p<0.01$ at 50 and 100 µg/mL) but had no inhibitory activity against P- and F1C-fimbriae dominated strain 2980. Quantitative gene expression analysis indicated that PAC-containing as well as PAC-depleted extracts increased the *fimH* expression in NU14. For strain 2980 the PAC-containing extract led to upregulation of P- and F1C-fimbriae, whereas the PAC-depleted extract had no influence on gene expression [Rafsanjany 2015].

An extract (not further specified) from concentrated cranberry juice (0.5 and 1 mg/mL) significantly ($p<0.05$) reduced biofilm formation of a mixture of fourteen strains of uropathogenic *E. coli* [Margetis 2015].

Pre-incubation of fimbriae expressing *E. coli* with a spray dried extract (41% PACs) inhibited adhesion to villi from pig jejunal mucosa by 75.3 and 95.8% at 20 and 100 µg respectively in strain $F4^+$, and by 100% at both concentrations in strain $F18^+$. Binding of isolated F4 and F18 fimbriae to pig intestinal epithelium was reduced by pretreatment of the fimbriae with 2 and 20 mg/mL of the extract [Coddens 2017].

A significant ($p<0.05$) inhibition of *Vibrio cholera* biofilm formation during the development/maturation stage by reducing the biofilm matrix production and secretion was observed after addition of a water-soluble cranberry extract (4.0% PACs) to the culture medium at 2 mg/mL. Downregulation of the expression of several genes responsible for the production of the bacterial polysaccharide and matrix proteins was observed [Pederson 2018].

A cranberry dry extract (DER 25:1, PACs>2.7%) significantly decreased adhesion of uropathogenic *E. coli* strains UTI89 to human T24 bladder cells and CFT073 to A498 kidney cells in a concentration-dependent manner from 250 to 2500 µg/mL ($p<0.05$ to 0.001). Urine samples of male volunteers (n=8) after consumption of 900 mg/day of the extract for 7 days inhibited adhesion of strain UTI89 to T24 cells, whereas the urine of female volunteers (n=8) remained without effect. Protein analysis of the urine samples indicated increased amounts of Tamm-Horsfall protein (syn. uromodulin) in the active samples [Scharf 2019].

PACs, consisting predominantly of epicatechin oligomers (degree of polymerization [DP] 3-5), inhibited the adherence of uropathogenic P-fimbriated *E. coli* to cellular surfaces containing α-Gal(1→4)β-Gal receptor sequences similar to those on epithelial cells of the urinary tract [Foo 2000a,b].

A non-dialyzable, high-MW fraction from cranberry juice (MW > 12000-15000) significantly ($p<0.01$) inhibited sialic acid-specific adhesion of several strains of *Helicobacter pylori* to immobilized human gastric mucus and to human gastric HT-29 cells at a concentration of 100 µg/mL [Burger 2000]. The IC_{50} of the fraction was below 100 µg/mL for adhesion of some clinical isolates of *H. pylori* to both human gastric mucus and cultured gastric epithelial cells [Burger 2002].

Confluent monolayers of gastric cell lines were exposed to suspensions from 83 different isolates of *H. pylori* in the presence and absence of a non-dialyzable, high-MW fraction from cranberry juice. Adhesion of two thirds of the isolates to gastric cells was inhibited by the fraction at 0.2 mg/mL. Only 13 isolates (16%) were resistant to both the fraction and metronidazole, and 30 (36%) were resistant to the fraction alone. There was no cross-resistance [Shmuely 2004].

High molecular weight PACs (100 µg/mL) were examined for their potential to reduce the initial adhesion of uropathogenic *E. coli* CFT073 and *E. faecalis* 29212 to two model materials (PVC and PTFE). The experiments demonstrated a decreased attachment of both bacteria to PVC and PTFE when either bacteria, the model materials or both bacteria and model materials were pretreated with PACs. The most potent reduction was seen with *E. faecalis* and coated material surfaces (90% inhibition with PVC; 88% inhibition with PTFE) [Eydelnant and Tufenkji 2008].

Immobilized oral bacterial fructosyltransferase (FTF, involved in the pathogenesis of dental diseases) was treated with non-dialyzable, high-MW material (NDM; MW 15000) from concentrated cranberry juice at concentrations between 0 µg/mL and 200 µg/mL, with or without the addition of salivary amylase. NDM attached firmly to immobilized FTF in a dose-dependent manner, and the attachment was reduced in the presence of

salivary amylase (affinity constant 10^6 M^{-1} and 0.2 x 10^6 M^{-1}, respectively). At 200 µg/mL, NDM with sucrose inhibited the activity of immobilized FTF by 63% within minutes as compared with sucrose alone [Feldman 2010].

PACs (100 µg/mL) completely suppressed swarming motility of *Pseudomonas aeruginosa* ($p<0.05$), while a weaker decrease was also observed after treatment with cranberry powder, natural cranberry juice, diet cranberry juice cocktail containing artificial sweeteners, and cranberry tea. Twitching and swimming motilities were reduced to a lesser extent by the PACs [O'May 2011].

A highly purified A-type PAC inhibited adherence of sensitive and multi-drug resistant strains of *E. coli* to vaginal and bladder epithelial cells dose-dependently up to 70% with 50 µg/mL ($p<0.001$) [Gupta 2012].

A-type PACs were significantly more effective ($p<0.05$) in increasing agglutination of extra-intestinal pathogenic *E. coli* 5011 as compared to B-type PACs. The reduction of invasion of gut epithelial Caco-2 cells by *E. coli* was also significantly ($p<0.05$) more pronounced with A-type PACs [Feliciano 2013].

Adhesion of different strains of uropathogenic *E. coli* and *Proteus mirabilis* to HT1376 human bladder carcinoma cells was dose-dependently reduced by A-type PACs (15, 25, 50, 75 and 100 µg/mL) by up to 75%, as compared to controls. A reduction in motility of two *P. mirabilis* strains was observed [Nicolosi 2014].

Addition of PACs at 100 µg/mL to agar plates reduced the swarming motility of *P. aeruginosa* and inhibited biofilm formation by 40.9% ($p<0.05$) and 55.7% ($p<0.01$) at 1 and 10 µg/mL respectively. Proteomic analysis of PAC-treated *P. aeruginosa* revealed upregulation of 12 proteins related to iron siderophores or cation transporters and 5 proteins putatively involved in amino acid synthesis. Two proteins related to ATP synthesis, a likely cytochrome C protein (PA2482) and several proteins involved in DNA and RNA synthesis were downregulated, and several citric acid cycle proteins were reduced. Murine macrophages (J774A.1) and human embryonic kidney cells (HEK293T/17) pretreated with 10 µg/mL PACs were significantly ($p<0.05$) prevented from *P. aeruginosa*-mediated lysis as compared to untreated control [Ulrey 2014].

A xyloglucan fraction inhibited the adhesion of uropathogenic *E. coli* CFT073 and UTI89 strains to T24 human bladder epithelial cells in a dose-dependent manner with half-maximal inhibitory concentrations of 0.82 and 0.66 mg/mL respectively. A non-dose-dependent response was shown for adhesion of enterohaemorrhagic E. coli O157:H7 to HT29 human colonic epithelial cells [Hotchkiss 2015].

A phenolic-free carbohydrate fraction from cranberry fruit, containing predominantly oligosaccharides with xyloglucan and arabinan residues, reduced biofilm production of the uropathogenic *E.coli* strain CFT073 and the non-pathogenic strain MG1655b by 50% at 1.25 mg/mL, but did not inhibit bacterial growth [Sun 2015].

Application of a combination of cranberry PACs (DP4 and DP9) with myricetin reduced the insoluble exopolysaccharide (EPS) content (>80% reduction vs. vehicle-control; $p<0.001$) produced by *Streptococcus mutans*-derived glucosyltransferases, which is essential for the initiation of cariogenic biofilms. The 3D architecture of biofilms showed a defective EPS-matrix and failure to develop microcolonies on saliva-coated hydroxyapatite surface. The mechanical stability of the biofilms was significantly ($p<0.001$) weakened [Kim 2015].

A cranberry juice powder dissolved in water to a 25% concentration significantly ($p<0.01$) reduced the adherence of various oral *Streptococcus* strains to saliva-coated hydroxyapatite beads. A non-dialyzable, high-MW fraction from cranberry juice (MW > 14000) at a concentration of 100 µg/mL significantly ($p<0.01$) inhibited biofilm formation by *Streptococcus mutans*, *S. criceti*, *S. oralis* and *S. mitis* on saliva-coated hydroxyapatite beads. At 500 µg/mL biofilm formation by *S. sobrinus* and *S. sanguinis* was also significantly ($p<0.05$) inhibited [Yamanaka 2004].

Adhesion of three different strains of *E.coli* to human buccal cells was significantly ($p<0.001$) reduced up to 80% by a dry extract at a concentration containing 180 µg/mL PACs [Margetis 2015].

At a concentration of 0.6-2.5 mg/mL a non-dialyzable, high-MW fraction from cranberry juice dissociated co-aggregates formed by a wide range of oral bacteria. Gram-negative bacteria were more sensitive than Gram-positive bacteria [Weiss 2002].

At 0.066-1.33 mg/mL a non-dialyzable, high-MW fraction (MW >15000) from cranberry juice significantly inhibited the activity of two components of dental biofilm, glucosyltransferase and fructosyltransferase ($p<0.05$); it also inhibited the adhesion of *Streptococcus sabrinus* to hydroxyapatite beads ($p<0.05$) [Steinberg 2004]. In the same concentration range the non-dialyzable fraction promoted desorption of *Streptococci* from dental biofilm in the presence and absence of extracellular glucans and fructans ($p<0.05$), although the effect was more pronounced in the absence of these polysaccharides [Steinberg 2005].

A-type PAC oligomers of defined DP influenced 3D biofilm architecture and *Streptococcus mutans*-transcriptome responses. Accumulation of biofilms formed in a saliva-coated hydroxyapatite biofilm model was significantly ($p<0.0001$) impaired by application of PACs, and genes involved in bacterial adhesion, acid stress tolerance and glycolysis were affected. Genes (*rmpC*, *mepA*, *sdcBB* and *gbpC*) associated with sucrose-dependent bacterial binding were repressed. PACs of DP 4 and DP 8 to 13 were most effective in disrupting bacterial adhesion to glucan-coated apatite surface (>85% inhibition vs. vehicle-control; $p<0.0001$) and gene expression [Feng 2013]. In a similar study, topical application of a purified PAC fraction resulted in significantly ($p<0.05$) reduced biomass and total amount of extracellular insoluble polysaccharides of *S. mutans* biofilms as compared to vehicle control [Koo 2010].

A-type PACs significantly ($p<0.05$) prevented biofilm formation of *C. albicans* in a dose-dependent manner (23% reduction at 6.25 µg/mL to 80% reduction at 100 µg/mL). At 25 and 50 µg/mL, adherence to oral epithelial cells was reduced by 42% and 90% respectively, with complete inhibition observed at 100 µg/mL. A similar effect was observed in adherence to saliva-coated acrylic resin discs [Feldman 2012].

Co-aggregation of dental plaque forming bacteria was tested with a combination of either *Streptococcus sanguinis* (Ss) with *Fusobacterium nucleatum* (Fn) or *Porphyromonas gingivalis* (Pg) with Fn. The crude non-dialyzable fraction from a juice concentrate (NDM) and its phenol-rich fraction prepared with 75% acetone (NDMac) were effective in inhibiting co-aggregation of Ss and Fn (MIC = 470 µg/mL) and of Fn and Pg (MIC = 940 µg/mL). Biofilm formation by three bacterial strains, *Streptococcus mutans*, *Streptococcus epidermidis* and a methicillin-resistant strain of *Staphylococcus aureus*, was significantly ($p<0.001$) reduced by NDMac at concentrations of 80 µg/mL and by NDM at 320 µg mL [Neto 2017].

Anti-inflammatory activity
A phenol-rich extract from fresh cranberries at 1, 10 and 50 µg/mL decreased COX-2 expression ($p<0.05$) and suppressed degradation of IκBα ($p<0.05$) in unstimulated HT-29 human colon adenocarcinoma cells cultivated in serum-free medium. In phorbol 12-myristate 13-acetate (PMA)-stimulated cells, increased COX-2 expression and IκBα degradation were reduced by pretreatment with the extract at 10 µg/mL ($p<0.05$) [Narayansingh 2009].

A defatted 90% methanolic extract from fresh fruits inhibited COX-2 activity in human T lymphocytes with an IC_{50} of 12.8 µg/mL and the NF-κβ transcriptional activation with an IC_{50} of 19.4 µg/mL. The release of IL-1β, IL-6, IL-8 and TNF-α from LPS-stimulated human peripheral blood mononuclear cells was significantly ($p<0.001$) inhibited at a concentration of 50 µg/mL. iNOS activity in murine RAW 264.7 cells remained unchanged [Huang 2009].

In J774 macrophages, LPS-induced NO production was inhibited significantly ($p<0.01$) by concentrations of 30 µg/mL and 100 µg/mL of an extract enriched in hydroxybenzoic and hydroxycinnamic acids, anthocyanins and flavonols. Significant effects on iNOS or COX-2 expression were not detected. In human THP-1 macrophages the extract (100 µg/mL) inhibited LPS-induced IL-6, IL-1β and TNF-α production [Kylli 2011].

IL-8 secretion from MKN-45 stomach cancer cells, induced by 25 isolated strains of *Helicobacter pylori*, was significantly ($p<0.001$) inhibited by an extract (5.4% total polyphenols, 11.2% total organic acids) at a concentration of 1 mg/mL [Matsushima 2013].

An extract (not further specified), and a polyphenol-rich fraction thereof, reduced LPS-elicited induction of IL-1β in mouse Raw 264.7 macrophages in a dose-dependent manner [Grace 2014].

In LPS-induced BV-2 microglia, an extract enriched in anthocyanins (20 µg/mL) significantly lowered levels of NO species by 36.5% ($p<0.0001$) and of ROS by 9.2% ($p<0.01$) [Ma 2018].

Pre-incubation of Caco-2/15 cells with three fractions from freeze-dried cranberries (250 µg/mL; low-, medium- and high molecular mass phenolics respectively) prevented iron/ascorbate-mediated lipid peroxidation and counteracted LPS-mediated inflammation significantly ($p<0.01$ to $p<0.001$). Increased pro-inflammatory cytokines (TNF-α and IL-6), COX-2 and prostaglandin E2 as well as elevated NFκB activation were decreased. Nrf2 downregulation was enhanced. Oxidative stress-dependent mitochondrial dysfunctions (rise in ATP production, upregulation of Bcl-2, decline of protein expression of cytochrome c and apoptotic-inducing factor) as well as changes in the protein expression of mitochondrial transcription factors (mtTFA, mtTFB1, mtTFB2) were restored by the high molecular phenolic fraction [Denis 2015].

At 10-50 µg/mL the non-dialyzable fraction (MW > 14000) from cranberry juice potently inhibited pro-inflammatory cytokine (IL-1β, IL-6, TNF-α) and chemokine (IL-8, RANTES) responses of a macrophage cell line triggered by LPS from the five major periodontopathogens ($p<0.05$) [Bodet 2006a]. The same fraction dose-dependently inhibited the proteolytic activities of several bacteria known to contribute to periodontal tissue destruction ($p<0.05$) [Bodet 2006b].

The effects of A-type PACs (25, 50, and 100 µg/mL) on MMP production in LPS-stimulated macrophages were investigated. The increased secretion of MMP-7, MMP-8 and MMP-13 was significantly reduced at all concentrations ($p<0.05$). The LPS-induced production of MMP-3 was only decreased at 100 µg/mL ($p<0.05$), and a synergistic effect was observed at 25 µg/mL. Elevated MMP-1 and MMP-9 secretion was diminished at 50 and 100 µg/mL ($p<0.05$). Pretreatment of the macrophages with the PACs significantly ($p<0.05$) reduced LPS-induced NF-κB p65 activation. The LPS-enhanced levels of phosphorylated JNK2 (Thr183/Tyr185), AKT (Ser473), AKT (Thr308), and MEK1 (Ser217/Ser221) were reduced with 50 µg/mL PACs. MMP-1 mediated type I collagen degradation and MMP-9-mediated gelatine degradation were inhibited significantly ($p<0.05$) at all concentrations [La 2009a].

Pretreatment of oral epithelial cells with A-type PACs (25, 50, and 100 µg/mL) prior to stimulation with *C. albicans* resulted in a significant decrease ($p<0.05$) of the elevated secretion of IL-6 and IL-8 in a dose-dependent manner. Pretreatment of the cells with 50 µg/mL of the fraction significantly ($p<0.05$) decreased *C. albicans*-induced activity of NF-κB p65 to the level of non-stimulated cells. Elevated levels of phosphorylated kinases AKT (Ser473), ERK1/2 (Thr202/Tyr204) and MEK1 (Ser217/Ser221) were significantly ($p<0.05$) reduced upon pretreatment at 50 µg/mL [Feldman 2012].

In human gingival epithelial cells and normal human gingival fibroblasts IL-17 stimulated the production of IL-6 ($p<0.005$) and IL-8 ($p<0.03$). Non-toxic levels of non-dialyzable high molecular material from juice inhibited constitutive IL-6 and IL-8 production by epithelial cells ($p<0.01$) and fibroblasts ($p<0.03$) as well as IL-17-stimulated cytokine production [Tipton 2013b].

Aggressive periodontitis (AgP) gingival fibroblasts were incubated with high molecular weight non-dialyzable material rich in PACs (NDM) from cranberry juice or NDM+LPS from *Fusobacterium nucleatum* or *Porphyromonas gingivalis*. NDM (50 µg/mL) inhibited LPS-stimulated NF-κB p65 ($p<0.003$) and constitutive or LPS-stimulated matrix metalloprotease (MMP)-3 ($p<0.02$). Constitutive or LPS-stimulated IL-6 production in AgP fibroblasts ($p<0.0001$) was increased by NDM, but inhibited in normal human gingival fibroblasts ($p<0.01$) [Tipton 2013a].

In human gingival epithelial cells IL-1β-stimulated IL-6 production was significantly decreased after incubation with NDM (25 µg/mL; $p<0.001$) or inhibitors of NF-κB or AP-1. The increased activation of NF-κB or AP-1 after IL-1β was reduced by NDM ($p<0.0001$). NDM did not significantly affect IL-1β-stimulated levels of phosphorylated intermediates in the NF-κB pathway (IκBa) or the AP-1 pathway (c-Jun, ERK1/2) [Tipton 2014].

Human temporomandibular joint synovial fibroblasts from joints with and without degenerative osteoarthritis were incubated with IL-1β (0.001–1 nM) and NDM (25–250 µg/mL). Increases of IL-6, IL-8 and VEGF production were dose-dependently reduced by NDM (25, 50, 100 and 250 µg/mL). NDM decreased IL-1β-elevated nuclear levels of NF-κB and AP-1 ($p<0.04$) [Tipton 2016].

Antimicrobial activity
Liquid extracts (50 µl of 3g of homogenated berries or berry cake in 10 mL acidified ethanol) showed activity against six Gram-positive and four Gram-negative bacteria, with *Bacillus cereus* being the most sensitive [Viskelis 2009].

Three cranberry extracts (enriched in water-soluble phenolic compounds (E1), apolar phenolic compounds (E2) or anthocyanins (E3)) were investigated against seven bacterial strains. The strongest effects were observed for E1 with MICs between 12.6 and 50.4 µg phenolics/well [Côté 2011].

Six different microorganisms (*Candida glabrata*, *C. lusitaniae*, *C. krusei*, *C. tropicalis*, *C. albicans* and *Cryptococcus neoformans*) were significantly ($p<0.001$) inhibited by an extract enriched in phenolics and four PAC-rich subfractions with MIC_{50} values between 0.5 and 63 µg/mL [Patel 2011].

Addition of 10% cranberry juice or of a PAC fraction (10, 50 or 100µg/mL) to the cultivation broth strongly increased the doubling time of *E.coli*. Altered expression of genes associated with iron transport and binding, the transcripts for essential metabolic enzymes, ATP synthesis, and fumarate hydratase was shown. The changed expression of genes associated with iron transport was attributed to the strong iron-chelating capacity of PACs. Addition of exogenous iron to the growth media partially reversed the inhibitory effect on bacterial growth [Lin 2011].

Three extracts standardized for PACs reduced the growth of *Staphylococcus spp.*, but not of *E. coli*, with MICs in the range 0.02–5 mg/mL. The extracts also inhibited biofilm production in several clinically relevant strains of *Staphylococcus* (*S. epidermidis*, *S. aureus*, methicillin-resistant *S. aureus*, *S. saprophyticus*) and *E. coli*, but did not eradicate the established biofilm [LaPlante 2012].

Treatment of *S. aureus* with a water-soluble extract (containing at least 88% carbohydrates and 2 to 3.8% total phenolic compounds) or an ethanolic extract from cranberry press-cake revealed a transcriptional signature typical of peptidoglycan-acting antibiotics (upregulation of genes *vraR/S*, *murZ*, *lytM*, *pbp2*, *sgtB*, *fmt*). The effect of the ethanolic extract on peptidoglycans was confirmed by the marked inhibition of incorporation of D-[^{3}H]alanine. The combination of β-lactams and this extract in checkerboard assays revealed a synergistic activity against *S. aureus* including strain MRSA COL. For this strain a 512-fold decrease of the MIC of amoxicillin in the presence of the ethanolic extract at 128 µg/mL was observed [Diarra 2013].

Growth of several pathogenic *E. coli* strains was significantly inhibited by an extract with defined PAC content at 50 to 1000 µg/mL ($p<0.04$ to 0.0001) [Margetis 2015].

A reduction in cell viability of approximately 40% was observed for monocyte-derived macrophages or oral epithelial cells treated with cell wall of *Peptostreptococcus micros*. Pretreatment of both cell lines with NDM dose-dependently reduced the toxic effect to approximately 15% ($p<0.05$) [La 2009b].

Polymeric PACs (mean DP 35) from lyophilized cranberries showed strong activity against *S. aureus* VTT E-70045 [Kylli 2011].

A potent and dose-dependent effect of PACs on the cytoskeleton of HeLA cells was demonstrated. Actin pedestal formation and localized actin polymerization required for infection with two strains of enteropathogenic *E. coli* and *S. typhimurium* were clearly diminished. Invasion of HeLa cells by *S. typhimurium* was reduced in a concentration-dependent manner. PACs had no effect on bacterial growth, nor the production of bacterial effector proteins of the type III secretion system [Harmidy 2011].

Different fractions from cranberry powder (sugars plus organic acids, monomeric phenolics, anthocyanins plus PACs, anthocyanins or PACs alone) were found to inhibit *E. coli* O157:H7, *Listeria monocytogenes* and *Lactobacillus rhamnosus* to various degrees, with *L. monocytogenes* being the most susceptible [Lacombe 2013].

Antiviral effects

Monolayers of monkey kidney epithelial-like MA-104 cells were inoculated with 0.2 ml cranberry juice before or after treatment with Simian rotavirus SA-11 and bovine reovirus type 3. Pretreatment of the monolayers at juice concentrations from 16% to 30% reduced reovirus infectivity titers by >90% and of rotavirus to a similar extent. Transmission electron microscopy did not detect virus penetration or egress among pretreated monolayers. Detection of rotavirus RNA was markedly reduced after pretreatment. Posttreatment was less effective in the reduction of viral infectivity titers than pretreatment [Lipson 2010].

The influence of cranberry juice and a PAC fraction on the infectivity of murine norovirus (MNV-1), feline calicivirus (FCV-F9), MS2(ssRNA) bacteriophage and phiX-174(ssDNA) bacteriophage was studied. Viruses (~7 log^{10} or ~5 log10 PFU/mL) were mixed with equal volumes of the juice or 0.30, 0.60, and 1.20 mg/mL final PAC concentration and viral infectivity was evaluated with plaque assays. At low viral titres, FCV-F9 was undetectable after all treatments. All other tested titres were reduced by the treatment [Su 2010].

Pretreatment of Vero cells with an extract (>360 mg/g PACs) resulted in a concentration-dependent inhibition of *Herpes simplex* virus 1 and 2 (IC_{50} against HSV-1 and HSV-2 replication 14.2 ± 0.5 mg/mL and 9.6 ± 0.2 mg/mL respectively). Two PAC-A containing fractions of the extract were shown to be responsible for the activity. Gene expression studies showed that the attachment of HS viral particles to the target cells was impaired at an early step in a concentration-dependent manner. The extract and the PAC fractions led to a loss of infectivity of the HSV particles by targeting the viral envelope glycoproteins gD and gB [Terlizzi 2016].

An extract (366 mg/g total PACs) inhibited influenza A and B virus replication in MDCK cells in a concentration-dependent manner with an IC_{50} value of 4.5 µg/mL for both viruses. The extract prevented the attachment and entry of the viruses and exerted virucidal activity. The extract and PAC-A2 directly interacted with the ectodomain of viral haemagglutinin (HA) glycoprotein [Luganini 2018].

Neuraminidase activity (NA) of influenza A and B strains was inhibited by NDM (MW 12,000-15,000). The most potent effect was observed against two H1N1 strains (IC_{50} 187 and 197 µg/mL respectively). The NA inhibition in two influenza B strains (IC_{50} 441 and 578 µg/mL respectively) and of bacterial neuraminidase of Streptococcus pneumoniae (IC_{50}, 594 µg/mL) was much less [Oiknine-Djian 2012].

Anticancer activity

An extract from cranberry fruit and fractions from it were tested for their ability to induce quinine reductase, an enzyme that can inactivate certain carcinogens, and to inhibit the induction of ornithine decarboxylase, an enzyme involved in tumour proliferation. The ethyl acetate fraction induced quinine reductase, doubling its activity at a concentration of 3.7 µg of tannic acid equivalent (TAE) per 150 µl of medium. The IC_{50} values (as TAE per 150 µl of medium) for inhibition of ornithine decarboxylase were 6.0 µg for the PAC fraction, 7.0 µg for the extract and 55.0 µg for the ethyl acetate fraction [Bomser 1996].

A fraction from a methanolic extract inhibited the growth of two human tumour cell lines with IC_{50} values in the range 16-125 µg/mL [Yan 2002].

The IC_{50} of a proanthocyanidin-rich fraction from an extract was 5.67 µg/mL in an ornithine decarboxylase assay, indicating a significant activity against the promotion stage of chemically-induced carcinogenesis [Kandil 2002].

Fractions of an extract enriched with sugars, organic acids, total polyphenols, PACs or anthocyanins were tested for antiproliferative effects against human cancer cell lines at concentrations corresponding to their content in the extract. The extract and all fractions except the sugar fraction showed significant antiproliferative activity compared to controls ($p \leq 0.01$), the total polyphenol fraction being the most active against all cancer cell lines [Seeram 2004].

Pretreatment with a proanthocyanidin-rich fraction inhibited viability and proliferation of SEG-1 human oesophageal adenocarcinoma cells in a time- and dose-dependent manner. At 50 µg/mL, acid-induced cell proliferation was also significantly reduced, apoptosis was induced and a cell cycle arrest at the G1 checkpoint occurred (all $p<0.05$) [Kresty 2008].

Gene expression analysis of NCI-H460 human lung cancer cells after treatment with 50 µg/mL of an A-type PAC (DP 4-5) fraction showed upregulation of numerous processes linked to cell death and downregulation of cell cycle linked processes. The treatment also resulted in significant ($p<0.05$) and rapid induction of apoptosis [Kresty 2011].

A PAC fraction from frozen fruits (PAC-1), consisting of mainly A-type PACs with DP 2 to 11, exhibited cytotoxicity against platinum-resistant human ovarian SKOV-3 cancer cells (IC_{50} = 79 µg/mL) by inducing classic apoptotic changes, but was non-cytotoxic to lung fibroblasts. Synergistic effects with paraplatin were observed: pretreatment of SKOV-3 cells with the fraction (106 µg/mL) led to a distinct reduction of the paraplatin IC_{50} value, and co-treatment revealed reduced cell proliferation at lower concentrations than individual treatment with the fraction or with paraplatin [Singh 2009]. Purification of this fraction resulted in fraction PAC-1A, which selectively reduced the viability of various human neuroblastoma cell lines and showed synergistic effects with cyclophosphamide [Singh 2012].

The proanthocyanidin-rich isolate PAC-1 inhibited viability and proliferation of chemotherapy-resistant SKOV-3 ovarian cancer cells by causing cell cycle arrest in the G2/M phase and increasing the generation of intercellular ROS. Apoptosis was induced through activation of caspases 3, 7 and 8, blocking of the activation of the pro-survival factor AKT and inactivation/ cleavage of DNA repair factor PARP. PAC-1 also blocked vascular endothelial growth factor (VEGF)-stimulated receptor phosphorylation in HUVEC cells [Kim 2012].

In human oesophageal adenocarcinoma cells, a PAC fraction (DP 4-5) at 50 and 100 µg/mL induced caspase-independent cell death mainly via autophagy and low levels of apoptosis in acid-sensitive JHAD1 and OE33 cells, but resulted in cellular necrosis in acid-resistant OE19 cells ($p<0.05$ as compared to vehicle treated cells). Cell death involved PI3K/ AKT/mTOR inactivation, pro-apoptotic protein induction (BAX, BAK1, deamidated BCL-xL, Cytochrome C, PARP), modulation of MAPKs (P-P38/P-JNK) and G2-M cell cycle arrest [Kresty 2015].

An extract from frozen fruits with sugars removed showed significant ($p<0.05$) and dose-dependent cytotoxicity against DU145 human prostate cancer cells at 10, 25 and 50 µg/mL with an IC of 46% at 50 µg/mL. At this concentration the extract led to an arrest in the G1 phase of the cell cycle associated with significant ($p<0.05$) decreases in the expression of CDK4, cyclin A, cyclin B1, cyclin D1 and cyclin E and increased expression of p27 [Deziel 2012].

A sugar-free extract and two fractions (rich in flavonoids and PACs respectively) reduced viability of human DU145 prostate adenocarcinoma cells in a dose- dependent manner with IC50 values < 50 µg/mL. Cell death occurred due to apoptosis as shown by increased caspase-8 and -9 activity [MacLean 2011].

A PAC-enriched fraction from frozen fruits decreased viability of DU145 prostate cancer cells by 30% at a concentration of 25 µg/mL. The fraction inhibited MMP 2 and 9 activity via an increase in the expression of TIMP-2 and a decrease in the expression of EMMPRIN. The expression of PI-3 kinase and AKT proteins and the translocation of the NF-kB p65 protein to the nucleus and c-fos protein levels were decreased. The phosphorylation of p38 and ERK1/2 as well as the c-jun protein levels increased [Deziel 2010].

In a similar experiment with a flavonoid fraction (25 µg/mL), viability of DU145 cells, as well as MMP-2 and MMP-9 activity, was decreased due to increased TIMP-2 expression. Urokinase plasminogen activator (uPA) activity was reduced through effects on specific temporal MMP regulators and uPA regulators and by affecting the phosphorylation and/or expression of specific MAP kinase, PI-3 kinase, NF-kB and AP-1 pathway associated proteins [MacPhee 2014].

In DU145 cells, a fraction containing A-type PACs (DP 2-12) at 25 µg/mL caused cell cycle arrest in the G2/M-phase, decreased the expression of cyclin A, cyclin B1, $p16^{INK4a}$, p21, and pRBp107 protein levels and increased protein expression levels of cyclin E, cyclin D1, CDK2, CDK4 and p27 [Kim 2014].

Antioxidant activity

Cranberry juice with a polyphenolic content corresponding to 1548 mg gallic acid equivalents/L inhibited cupric ion-dependent low density lipoprotein (LDL) oxidation at a dilution of 0.1% ($p<0.001$) [Wilson 1998].

Ethyl acetate fractions from cranberry containing mainly flavonol glycosides and anthocyanins showed 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical-scavenging activity with EC_{50} values of 33-40 µg/mL. Cyanidin 3-galactoside exhibited the highest antioxidant activity (EC_{50}: 1.45 µM) in LDL + VLDL oxidation assays, comparable to tocopherol [Yan 2002].

Moderate free radical-scavenging activities and inhibition of lipid peroxidation were observed for fractions from cranberries and cranberry pomace [Caillet 2011, 2012].

Fractions enriched in free, esterified or bound phenolics prepared from different cranberry genotypes showed antioxidant activity in several assays (ORAC, Trolox equivalent antioxidant activity, TBARS, ferric reducing capacity and others) [Abeywickrama 2016].

Effects on enzymes involved in drug metabolism

In human liver microsomes, with the use of mycophenolic acid as a probe, UDP-glucuronosyltransferase (UGT) 1A9 was weakly inhibited by a juice (>40% total PACs) with an IC_{50} of 260 µg/mL [Mohamed and Frye 2011].

A methanolic extract was tested for CYP2C8 inhibition in human liver microsomes with amodiaquine and pioglitazone as probes. The formation of the metabolites N-desethylamodiaquine and hydroxypioglitazone was reduced with IC_{50} values of 24.7 and 24 µg/mL respectively [Albassam 2015].

Fractions from a methanolic extract of freeze-dried juice were tested for their inhibitory potential on recombinant CYP3A4 and CYP3A5 enzymes with the probe midazolam. At 10 µg/mL, the inhibition towards rCYP3A4 varied from 10% (butanol-soluble) to 50% (hexane-soluble) and the extent of inhibition toward rCYP3A5 from 0% (chloroform-soluble) to

23% (hexane-soluble). The hexane-soluble fraction differed significantly ($p<0.05$) from all other fractions. At 50 µg/mL, the hexane- and chloroform-soluble fractions reduced rCYP3A4 activity by at least 75%. Towards rCYP3A5 the inhibition by all fractions was much less with the hexane-soluble fraction resulting in the strongest effect (62% inhibition) [Ngo 2009].

Maslinic and corosolic acid, isolated from a methanolic extract in an activity-guided approach, showed the strongest inhibition of enteric CYP3A activity for the substrate midazolam. The IC_{50} values were 7.4 and 8.8 µM for maslinic and corosolic acid respectively, using human intestinal microsomes and 2.8 and 4.3 µM respectively, using recombinant CYP3A4 as the enzyme source [Kim 2011a].

Other effects
Cranberry juice at a concentration of 1% dilated phenylephrine-induced contractions in rat aortic rings ($p<0.002$). The vasodilation was shown to be dependent on endothelial cell nitric oxide formation [Maher 2000].

Human retinal pigment epithelium cells (ARPE-19) were irradiated with blue light to mimic age-related macular degeneration. Treatment with an ethyl acetate extract from a concentrated juice at 12.5, 25 or 50 µg/mL resulted in a significant ($p<0.05$) increase of proliferation. Similar effects were seen after treatment with the non-condensed and the condensed tannin fraction of the ethyl acetate extract [Chang 2017].

An extract, its ethyl acetate fraction, water fraction and three subfractions significantly ($p<0.05$) inhibited formation of glycated haemoglobin in human blood. Most of the fractions reduced glucose-mediated glycation of human albumin with EC_{50} values from 21-52 µg/mL, better than aminoguanidine (EC_{50} 64 µg/mL) as positive control [Liu 2011]

Formation of fructose-induced glycation end-products was reduced by an anthocyanin-enriched fraction (100 µg/mL) by 74.5%. A significant ($p<0.0001$) inhibition of Aβ-fibrillation was observed in two models. H_2O_2-induced cytotoxicity in BV-2 microglia decreased by 18.7% ($p<0.001$) [Ma 2018].

In differentiated 3T3-L1 adipocytes, treatment with an aqueous extract (25-100 µg/mL) decreased lipid accumulation and generation of reactive oxygen species. Adipogenesis and lipogenesis were suppressed via downregulation of the expression of *PPARγ* and other genes. The extract significantly increased the expression of adiponectin ($p<0.001$ at all concentrations) and decreased leptin expression ($p<0.001$ at 100 µg/mL) [Kowalska 2017].

Pretreatment of neuroblastoma SH-SY5Y cells with lyophilized cranberry juice (25, 50 and 100 µg/mL) for 24 h significantly increased cell viability after exposure to hydrogen peroxide (100 µM) ($p<0.05$ to 0.01). The juice increased mitochondrial activity, reduced intracellular ROS production and lipid peroxidation due to hydrogen peroxide and upregulated the activity of catalase ($p<0.05$) and superoxide dismutase ($p<0.01$) [Casedas 2018].

An anthocyanin-fraction increased Akt phosphorylation in a dose-dependent manner in HUVECs. Cell migration and capillary-like tube formation were significantly ($p<0.01$) enhanced at a concentration of 0.2 mg/mL. The effects were abolished by pretreatment with wortmannin, a PI3 kinase inhibitor [Tulio 2012].

A fraction enriched in A-type PACs (10, 25 and 50 µg/mL) significantly decreased the formation of differentiated osteoclasts in a dose-dependent manner ($p<0.05$, 0.01 and 0.01, respectively) via an inhibition of cell maturation of pre-osteoclastic cells exposed to RANKL and M-CSF. The secretion of IL-8, involved in osteoclastogenesis, was significantly increased, whereas MMP-2 and -9, related to the resorptive activity of osteoclasts, were reduced ($p<0.01$ for all experiments). A significant ($p<0.05$) reduction of released helical peptides from the bone matrix was observed upon treatment of osteoclasts [Tanabe 2011].

Complexes of oligomeric PACs (DP 2-11) with bovine serum albumin significantly ($p<0.05$) reduced COX-2 and iNOS expression in LPS-stimulated RAW 264.7 macrophages in a concentration-dependent manner. The effects of the same concentrations of PACs alone were less pronounced. PACs complexed with hen egg-white lysozyme modulated antigen uptake, processing and presentation in murine peritoneal macrophages as shown by an increase of IL-2 expression in co-cultures with a T-cell hybridoma line [Carballo 2017].

In vivo experiments

Anti-adherence activity
Urine collected from mice receiving a cranberry cocktail (not further specified) for 14 days in place of normal drinking water, inhibited the adherence of *E. coli* to uroepithelial cells by approximately 80% ($p<0.01$) [Sobota 1984]. After administration of cranberry juice (25% or 100%; 3 x 1 mL/d for 3 days) to Sprague-Dawley rats, urine was collected. Treatment of uropathogenic *E.coli* with the urine significantly reduced the adhesion to human urinary bladder carcinoma T24 epithelial cells ($p=0.0181$ for 25% juice and $p=0.0045$ for 100%). Haemagglutination of a fimbriated *E.coli* strain decreased by 40.9% ($p=0.0038$) and 39.8% ($p<0.021$), biofilm formation by 53.9% ($p=0.0006$) and 72.9% ($p=0.0001$), respectively [Chen 2013].

Dogs with recurrent history of UTIs received orally either a cranberry extract (not further specified; 1 g/d for dogs < 25 kg and 2 g/d for dogs > 25 kg; n=6) for 6 months or cephalexin (20 mg/kg twice daily; n=6) for fourteen days. None of the dogs developed a UTI during the 6 months. Urine collected from the cranberry group on day 30 significantly ($p<0.05$) reduced bacterial adhesion of different E. coli strains to MDCK cells as compared to urine samples obtained before extract administration. The day 60 urine showed significantly ($p<0.05$) better effects than days 0 and 30 urine [Chou 2016].

Urine samples from Sprague-Dawley rats collected 2, 4, 8 and 24 hours after a single oral dose of an extract (100 mg/kg containing 15% total PACs) were studied for inhibition of adhesion of P-fimbriated E. coli to HAT-29 cells. The 8 h sample showed the highest activity ($p<0.05$). A 47% reduction in *E. coli* binding was still evident with the sample collected after 24 h [Peron 2017a].

In piglets on standard chow or chow supplemented with 1g/kg or 10 g/kg cranberry extract (41% PACs) for three days before and eight days after challenge with $F18^+$ *E. coli*, no differences in faecal excretion of *E.coli* were observed. In a second approach with 1% extract in the chow and 0.1% in the drinking water, a decrease of *E. coli* in the faeces was observed with significant overall reduction ($p<0.0001$). Score and duration of diarrhoea were also significantly reduced ($p<0.05$ at days 3 to 7 for score and $p=0.038$ for duration). Total serum antibody and IgM levels were significantly lower ($p<0.001$ and 0.01 respectively) [Coddens 2017].

Protective effects on intestinal mucosa and kidney
In male IRC mice, dysfunction of the mucosal immune system

and a suppression of the mucosal barrier function was induced by elemental enteral nutrition (EEN). Mice received 8 mg, 50 mg or 100 mg PACs/kg b.w. in addition to EEN for five days. Body weights were significantly ($p<0.05$) lower in all EEN groups as compared to the group on standard chow. Decreased intestinal tissue IL-4 and IL-13 levels after EEN were significantly ($p<0.05$) improved by 100 mg PACs and by 8, 50 and 100 mg PACs, respectively. IL-1β, IL-6 and TNF-α remained unchanged by EEN or EEN+PACs. Goblet cell numbers and luminal mucin 2, reduced with EEN, were attenuated ($p<0.05$) with 50 and 100 mg PACs [Pierre 2013].

In a similar experiment with only one PAC group (100 mg/kg), decreased phosphorylated STAT-6, polymeric immunoglobulin receptor and small intestine luminal IgA concentrations after EEN were significantly ($p<0.05$) improved with the extract [Pierre 2014].

Cranberry juice (15%; 1 mL/d) was administered orally to female LACA mice for 14 days. On day 15 the animals were infected by introduction of *Pseudomonas aeruginosa* PAO1 into the bladder. Significantly ($p<0.001$) lower renal colonization with bacteria was observed in the cranberry group as compared to untreated controls 5 days after infection. Inflammation with infiltration of polymorphonuclear leukocytes into the interstitium, vascular permeability and destruction of glomeruli and tubules in renal tissue was reduced by the treatment as well as the expression of renal pathology markers, MDA and RNI ($p<0.01$) [Harjai 2014].

Effects on life span
The life span of *Caenorhabditis elegans* wild-type N2 worms was increased by an extract (not further specified; 2 mg/mL) from 12 to 15.9 days. Life span extension was induced via the insulin/IGF signalling pathway and the nuclear localisation of the gene *DAF-16* through osmotic stress resistant-1 and its downstream effector UNC-43. Concentrations of > 6 mg/mL reduced the mean life span. In different stress models, higher resistance of worms (pretreated with 2 mg/mL of the extract for two generations) to heat shock and to osmotic stress was observed [Guha 2013].

Feeding of *C. elegans* with a uropathogenic *E. coli* strain reduced lethal time 50% (LT50) from 279.6 hours (feeding on non-virulent *E. coli* OP50) to 97.6 hours. Pretreatment of uropathogenic *E. coli* with urine from rats which had received cranberry juice (25% or 100%; 3 x 1 mL per day for 3 days) resulted in an improvement of the reduced LT_{50} to 117.4 hours (25% juice) and 158.1% (100% juice) [Chen 2013].

Addition of 2 mg/mL of a water-soluble cranberry extract (standardized to 4.0% PACs) to the growth medium significantly extended the life span of *C. elegans* CL2006 worms (expressing β-amyloid (Aβ) peptides) by 16.2% from 14.8 to 17.2 days ($p=0.006$), and delayed paralysis due to Aβ toxicity via heat shock transcription factor (HSF)-1. The total amount of Aβ species in the cranberry-treated worms was around 20% less than in controls ($p<0.05$). The extract also significantly ($p<0.05$) enhanced the solubility of proteins in aged worms [Guo 2016].

Life span in three life stages (healthy span 3–30 days, transition span 31–60 days and senescence span 61 days to the death of all flies) of adult *Drosophila* flies was extended by addition of 2% of a PAC-enriched extract to their diet. Life span extension was associated with reduced phosphorylation of ERK, slightly increased phosphorylation of AKT and a reduced level of 4-hydroxynonenal protein adducts [Sun 2014].

Addition of 5 and 20 mg/mL of an extract enriched in anthocyanins to the diet of male fruit flies increased the mean life span from 48 to 51 ($p<0.05$) and 53 ($p<0.01$) days respectively. The higher dose significantly delayed the age-dependent decline in climbing activity compared with control ($p<0.01$). The effects were accompanied by upregulation of the ageing-related genes SOD1 and downregulation of MTH, InR, TOR and PEPCK [Wang 2015].

In male ICR mice ageing was accelerated by 80 mg/kg/d galactose i.p. for 8 weeks. Oral treatment with a cranberry concentrate (15, 30 and 60 mg/kg/d PACs) resulted in a reduction of elevated hepatic and brain TBARS and serum and brain MAO levels. Hepatic CAT activity was significantly decreased by all doses ($p<0.05$). The lowest dose also significantly lowered the plasma 8-isoprostane level [Jiao 2017].

Anti-inflammatory effects
Male Sprague-Dawley rats received an atherogenic diet supplemented with 5 and 10% freeze-dried cranberry powder for 6 weeks. After challenge with LPS (0.5 mg/kg i.p. 15 hours prior to sacrifice) significantly ($p<0.05$) lower mean serum levels of CRP and IL-1β and higher serum IL-10 and NO levels were observed in the cranberry groups [Kim 2011b].

Colitis was induced in mice with dextran sulphate sodium (DSS) for 7 days in weeks 3 and 6 of feeding with either normal chow, chow containing 0.1% or 1% cranberry extract (not further specified) or 1.5% whole dried cranberry powder (DC). Animals on the high extract dose and on DC showed a later onset of colitis and a lower disease activity index in both weeks on DSS. DSS-induced shortening of the colon and increased colonic myeloperoxidase were significantly improved by DC ($p<0.05$). DC treatment resulted in reduced structural damage in colonic mucosa and less infiltration of inflammatory cells when compared to DSS alone. All cranberry treatments significantly reduced serum levels of TNF-α compared to DSS control, while DC also significantly reduced serum IL-1β (both $p<0.05$) [Xiao 2015].

Addition of 0.8% of a polyphenol-rich cranberry fraction (80.9% total phenolics; approx. 0.1% dimeric PACs and 0.7% anthocyanins) to the diet of high fat (HF)-fed obese C57BL/6J mice for 10 weeks resulted in a significant decrease in plasma ALT (31%, $p<0.01$) and in histological severity of non-alcoholic fatty liver disease (33% reduction in area of involvement, $p<0.01$; 29% decrease in lipid droplet size, $p<0.05$) compared to only HF-fed control mice. Hepatic protein levels of TNF-α and C-C chemokine ligand 2 were reduced by 28% ($p<0.01$) and 19% ($p<0.05$) respectively. The extract also decreased hepatic mRNA levels of toll-like receptor 4 (63%) and NF-κB (24%), as well as a number of downstream target genes and markers of macrophage infiltration [Glisan 2016].

Mice received a methanolic extract at doses of 50 and 200 mg/kg p.o. for 10 days. The extract significantly ($p<0.05$) reduced carrageenan-induced paw oedema by 42.9% and 36.9% after 5 hours respectively. Increased lipid peroxidation and influx of neutrophils, as measured by myeloperoxidase activity, in inflamed paws were decreased by both doses of the extract, significantly ($p<0.05$) only at the high dose [Nardi 2016].

A hydroethanolic extract (50, 100, and 200mg/kg) or vehicle was administered orally to mice at 1, 25 and 49 hours after induction of acute pancreatitis. The extract decreased L-arginine-induced abdominal hyperalgesia (from 48 to 72 h) and pancreatic oedema, pancreatic and pulmonary neutrophil infiltration, as well as levels of TNF-α, IL-1β and IL-6 after 72 h. Hyperamylasaemia and hyperlipasaemia were also reduced in comparison to the vehicle-treated group. Moreover, lipoperoxidation, carbonyl radicals, non-protein sulfhydryl

groups, and activity of catalase and superoxide dismutase, but not glutathione peroxidase, were restored by the extract [Santana 2018].

Experimental periodontitis in female BALB-c mice induced by mixed infection with *Porphyromonas gingivalis* and *Fusobacterium nucleatum* resulted in distinct alveolar bone loss after 42 days, which was significantly less ($p<0.05$) following pre-treatment of the two strains with NDM (MG > 12.000) from cranberry juice (4 mg/mL) and addition of the same dose of NDM to the drinking water of the mice [Polak 2013].

Antitumour effects
Chemopreventive effects of cranberry juice concentrate were evaluated in a model of bladder cancer in female Fischer-344 rats given N-butyl-N-(4-hydroxybutyl)-nitrosamine (150 mg, 2 x per week for 8 weeks). Cranberry juice concentrate (1.0 or 0.5 mL/rat/d), or water only, was administered by gavage for up to 6 months, starting one week after the final dose of the carcinogen. A dose-dependent effect of cranberry treatment was observed, with a reduced number of bladder tumours (-38%) in the 1.0 mL cranberry group compared to the water only control. The extract neither affected body weight gain nor caused other signs of toxicity [Prasain 2008].

Colon tumours were induced in male Fischer-344 rats by injection of azoxymethane at the age of 7 and 8 weeks. From week 4 the animals received either standard rodent feed, standard feed supplemented with 5 or 10% cranberries, or 2.5% and 5% cranberry juice for 42 weeks. A significant ($p<0.05$) reduction in the number of tumours, tumour size and the ratio of tumours/tumour bearing rat was observed in all cranberry groups as compared to control with the cranberries showing better effects than the juice. Activities of SOD and CAT increased in all cranberry groups [Sunkara 2009].

BALB/c nu/nu mice were inoculated s.c. with 5×10^6 human gastric SGC-7901 cancer cells pretreated with 0, 5, 10, 20 or 40 mg/mL of a dry cranberry extract (80% acetone). After 28 days, mean tumour diameter and weight of xenografts in the 10 and 20 mg cranberry groups were significantly lower than those in the control group ($p<0.05$ and 0.001 respectively). Tumour volume was also reduced ($p<0.05$ after 20 mg/mL). Mice did not develop any tumours with 40 mg/mL [Liu 2009].

An acidic ethanolic extract (yield 12.5%) was administered orally to male CD-1 mice at 200, 400 and 800 mg/kg b.w. daily for one week, concurrently with 200 mg/kg/day p.o. benzo[a] pyrene (B[a]P). Other groups received either no treatment, B[a]P 200 mg/kg alone or the cranberry extract alone at 800 mg/kg. B[a]P-induced increased frequency of micronucleated normochromatic erythrocytes was significantly ($p<0.05$) and dose-dependently reduced by all doses of the extract. The decrease in the index of polychromatic/normochromatic erythrocytes caused by B[a]P was significantly ($p<0.05$) improved by the highest extract dose [Madrigal-Santillan 2012].

The effects of freeze-dried cranberry powder were investigated against colitis-associated colon tumorigenesis induced by azoxymethane/dextran sulphate sodium in mice. The animals received a basal diet or the same diet containing 1.5% cranberries for 20 weeks. The supplementation resulted in a significant reduction of tumour incidence, multiplicity, burden, and average tumour size (all $p<0.05$) compared to the group on the basal diet. Gene and protein expression levels of pro-inflammatory cytokines IL-1β, IL-6, and TNF-α were significantly decreased (all $p<0.05$). Multiple signalling pathways/proteins related to inflammation, cell proliferation, apoptosis, angiogenesis and metastasis in the colon, such as COX-2, HO-1, NQO1, p-PI3K, PI3K, p-Akt, Akt, p21, p27, cyclin D1, CDK 4, p-Rb, EGFR, p53, cleaved caspase-3, cleaved PARP, VEGF, MMP-2, and MMP-9 were improved [Wu 2018].

An NDM fraction (MG 12,000–30,000) from cranberry juice inhibited the growth of tumours after i.p. inoculation of Balb/C female mice with Rev-2-T-6 lymphoma cells. The animals received 160 mg/kg i.p. the day after inoculation and 80 mg/kg/d for a further 2 weeks. A second group received half of these doses in the same regimen. Sixty days after inoculation 4 out of 5 mice without NDM developed tumours. In both NDM groups tumours were observed in none of the animals due to an increase in the immune response toward Rev-2-T-6 cells [Hochman 2008].

Oral administration to mice of a PAC fraction (DP 4-5, 250 µg/mouse, 6 days a week for 19 days) inhibited human oesophageal adenocarcinoma OE19 tumour growth by 67.5% via modulation of AKT/mTOR/MAPK signalling and induction of the autophagic form of LC3B [Kresty 2015].

Effects on lipids and glucose metabolism
Male Sprague-Dawley rats received either an atherogenic diet (HFC) or atherogenic diet supplemented with 2% or 5% cranberry powder for 6 weeks. Serum total cholesterol and LDL-cholesterol levels were not significantly different with the addition of cranberry powder. However, serum HDL-cholesterol level was significantly increased and serum protein carbonyl and TBARS levels significantly decreased in the 5% cranberry group compared with the HFC control (all $p<0.05$). Plasma FRAP value tended to be increased by cranberry powder [Kim 2008].

In Golden Syrian hamsters fed with a high-fat, high-cholesterol diet, addition of 2% cranberry concentrate powder (2-3.8% total phenolics, 0.3-1% total anthocyanins) to the diet for 20 weeks resulted in significantly reduced ($p<0.05$) liver weight to body weight ratio, heart rate, blood pressure and aortic esterified cholesterol concentrations. HDL- to VLDL- and HDL to LDL-cholesterol ratios remained unchanged [Kalgaonkar 2010].

The effect of a polyphenol-rich cranberry powder (CP) on metabolic parameters associated with metabolic syndrome was investigated in growing rats fed a high fructose diet (HFD, containing 58% fructose) or the HFD diet containing an additional 3.3, 6.6 or 33 g CP/kg for eight weeks. Fasting plasma glucose and triglycerides were reduced by the addition of CP to HFD. The AUC following an oral glucose tolerance test was 35–50% higher in animals fed the HFD vs. a starch-based control diet, and was decreased to control levels by the low or medium CP diet. CP tended to lower fasting plasma insulin. Homeostatic models of insulin resistance and β-cell function were lowest in animals fed low or medium CP diets ($p<0.05$). Rats on the control diet had a slightly higher food intake, final body weight and abdominal fat compared to animals on the other diets. Kidney weight was higher in the HFD group while CP decreased kidney weight to normal levels [Khanal 2010a].

A further study investigated the effect of cranberry pomace on selected metabolic parameters (increased fasting plasma insulin, cholesterol, and triacylglycerols (TAG), post-prandial plasma TAG homeostatic assessment models of insulin resistance and β-cell function) associated with high fructose feeding (58% by weight) in growing Sprague–Dawley rats. Addition of 1.5 or 3% extruded or un-extruded pomace to the high fructose diet for 8 weeks effectively ameliorated fasting plasma insulin, cholesterol, TAG level and insulin resistance. The best effects were observed with 3% extruded pomace [Khanal 2010b].

Male Sprague-Dawley rats received an atherogenic diet alone or supplemented with 5 or 10% freeze-dried cranberry powder for 6 weeks and were subsequently challenged with LPS (0.5 mg/kg i.p.) 15 hours prior to sacrifice. Mean serum HDL-cholesterol was significantly ($p<0.05$) higher in rats receiving 5% cranberry powder as compared to the atherogenic diet alone [Kim 2011b].

Male Fischer 344 rats were fed normal rodent chow with or without 2% cranberry powder from 6 to 22 months of age. Both groups displayed an age-related decline in basal plasma insulin concentrations, which was significantly ($p<0.05$) delayed by cranberry with a portal insulin concentration 7.6-fold higher at the end of the study, coupled with improved β-cell function. Supplementation led to increased β-cell glucose responsiveness during an oral glucose tolerance test, but insulin resistance values were similar in both groups. Total β-cell mass and expression of pancreatic and duodenal homeobox 1 and insulin within islets were enhanced, and insulin release from insulin-producing β-cells was increased [Zhu 2011].

Dietary supplementation of normal and obese C57BL/6 male mice with 2% of an ethanolic extract from cranberries (enriched in flavonoids) in addition to low-fat or high-fat diet resulted in an amelioration of insulin resistance and plasma lipid profile in obese mice, and a reduction of visceral fat mass. The adiponectin-AMPK pathway was identified as the main mediator of the improvement. In contrast, the reduced plasma atherogenic cholesterol observed in normal mice with cranberry supplementation was correlated to a downregulation of the hepatic cholesterol synthesis pathway [Shabrova 2011].

Daily treatment of ovariectomised rats with cranberry juice at 7 mg/kg for 8 weeks returned circulating levels of TC, triglycerides, HDL, non-HDL, and non-HDL/HDL cholesterol ratio close to normal values ($p<0.01$ to 0.001). Juice consumption improved endothelium-dependent relaxation in the aorta of the rats ($p<0.001$) by restoring phosphorylated eNOS levels, reversing the up-regulated levels of the renin–angiotensin system and normalising the elevated NAD(P)H oxidase expression and oxidative stress [Yung 2013].

Obese diabetic C57BL/KsJ-*db/db* mice received either a normal diet (control) or an atherogenic diet with or without the addition of 5 or 10% cranberry powder (120mg anthocyanins/100g; 2.6 g PACs/100g) for 6 weeks. Consumption of the atherogenic diet resulted in elevated serum total cholesterol and atherogenic index (AI), and reduced HDL-cholesterol. With 10% cranberry powder, mean HDL-cholesterol was increased close to control levels, whereas the AI remained higher than in the control rats. LPS-induced elevated serum insulin was lowered by more than 60% with both amounts of cranberry powder ($p<0.05$), and mean serum glucose level was reduced by approximately 19% with the lower amount ($p>0.05$). Mean activity of liver cytosolic glutathione peroxidase was significantly increased by LPS but found to have comparable values to without LPS in the 10% cranberry group ($p<0.05$). A reduction of approximately 89% in serum protein carbonyl was also observed at the higher amount ($p>0.05$) [Kim 2013].

The effects of consuming a diet enriched with 2% of a cranberry extract (88.8 mg PACs and 2.5 mg anthocyanins/g) for 28 days on the antioxidant status of non-obese mice and mice with monosodium glutamate–induced obesity were examined. Only in obese animals did the extract reduce the MDA content in erythrocytes and increase the activity of NAD(P)H:quinone oxidoreductase in the liver, which was accompanied by an increase in the corresponding mRNA levels. Catalase activity was raised in erythrocytes and the small intestine (all $p<0.01$) [Bousova 2015].

The effects of a cranberry extract (200 mg/kg p.o. for 8 weeks) were compared in C57Bl/6J male mice receiving either normal chow or a high fat-high sucrose (HFHS) diet to induce obesity. The extract significantly reduced HFHS-induced weight gain and visceral obesity ($p<0.05$) and decreased liver weight and triglyceride accumulation in association with blunted hepatic oxidative stress and inflammation. Insulin sensitivity improved, as revealed by improved insulin tolerance, lower homeostasis model assessment of insulin resistance and decreased glucose-induced hyperinsulinaemia during an oral glucose tolerance test. The extract lowered intestinal triglyceride content and alleviated intestinal inflammation and oxidative stress. The treatment markedly increased the proportion of the mucin-degrading bacterium *Akkermansia* in the gut microbiota [Anhe 2015].

In another study, the animals received the different diets for 3 weeks, then 8 weeks of treatment with the same extract as above. The extract did not reverse weight gain or fat mass accumulation in either diet group, but did fully reverse hepatic steatosis in the obese group, which was linked to upregulation of genes involved in lipid catabolism (e.g. PPARα, PPARγ; $p<0.001$) and downregulation of pro-inflammatory genes (e.g. COX2, NF-κB; $p<0.001$; TNFα $p<0.05$) in the liver. The extract also improved glucose tolerance and normalized insulin sensitivity in obese mice. The gut microbiota of obese mice significantly ($p<0.001$) changed in the cranberry group [Anhe 2017].

Male Wistar rats (120 days old) were fed either a standard diet (SD) or a high fat diet to induce obesity for 30 days. Both obese and normal rats subsequently received by gavage either 200 mg/kg cranberry extract/d (4 mg total polyphenols) or water as a control for a further 30 days. At the end of the study, body weights in the high fat + cranberry group were significantly lower ($p<0.05$) compared to high fat controls, and comparable to rats on the SD or cranberry-supplemented SD. Supplementation of the high fat diet with cranberry also resulted in less visceral fat, corticosterone, liver glucocorticoid sensitivity, cholesterol and triglycerides, and microsteatosis. High fat diet-increased lipid peroxidation in plasma and tissues, as well as higher protein carbonylation in liver and adipose tissue, was improved by the cranberry supplementation [Peixoto 2018].

Wistar rats received either a high fat diet (HFD) or a high fat diet supplemented with 3% unextruded cranberry pomace (UCP; with 32 mg/100 g anthocyanins and 59 mg/100 g flavonols) or 3% extruded cranberry pomace (ECP; no anthocyanins and 7.5 mg/100 g flavonols) for 8 weeks to study the effects on faecal fat excretion, liver index, lipid and carbohydrate metabolism, and the inhibition of oxidative stress due to HFD. Both supplements significantly improved the plasma antioxidant capacity and decreased lipid peroxidation ($p<0.05$). The addition of UCP significantly ($p<0.05$) increased faecal lipid excretion and decreased serum triglycerides [Bajerska 2018].

Hamsters were randomly assigned to either a high-cholesterol control diet (HCD), an HCD diet supplemented with 1% cranberry anthocyanins (CL) or an HCD diet supplemented with 2% cranberry anthocyanins (CH), for six weeks. Plasma total cholesterol and aorta atherosclerotic plaque decreased dose-dependently with increasing amounts of cranberry anthocyanins, whereas the excretion of both neutral and acidic sterols increased as compared to HCD ($p<0.05$ for CH). mRNA levels of intestinal genes of transporters, enzymes and proteins involved in cholesterol absorption and metabolism remained unchanged [Wang 2018].

Cranberry powder (4% PACs) at concentrations of 0.016% and 0.08% dose-dependently reduced fat accumulation in Caenorhabditis elegans ($p<0.05$) by 43% and 74%, respectively,

without affecting food intake, locomotor activities or body size. In mutant worms, the effects on different genes involved in lipogenesis were established in detail [Sun 2016].

Antimicrobial activity
Over 5 days eighty mice were infected on three occasions with *H. pylori* and two weeks later randomly allocated to four groups for various oral treatments: 0.5 mL of a cranberry juice daily for 30 days; triple therapy (amoxicillin 50 mg/kg, bismuth subnitrate 6.15 mg/kg and metronidazole 22.5 mg/kg, daily for 14 days), a combination of cranberry juice and triple therapy; or no treatment (control). The "clearance rate" for *H. pylori* was assessed after 24 hours, the eradication rate 4 weeks after treatment. The clearance rate was 80% in the cranberry group, 100% in the triple therapy group and 90% in the combination group compared to the control group. The eradication rate in the cranberry group was only 20% compared to 80% in the triple therapy group and 80% in the combination group.
In a prevention study, mice were treated with 0.5 mL of cranberry juice daily for 30 days and in the last 5 days (days 26-30) divided into four groups. One group was challenged orally with *H. pylori* on days 26, 28 and 30 (when the mice were not given juice), a second group with *H. pylori* suspended in cranberry juice, a third group with *H. pylori* 6 hours after receiving juice, and a control group with *H. pylori* but no cranberry juice. None of the mice were protected from infection and the numbers of colonizing bacteria were not reduced [Xiao 2003].

In a mouse model of mastitis, *S. aureus*-infected mammary glands were treated with either amoxicillin (0.005 mg/gland), an ethanolic extract of cranberry pomace (20 mg/gland) or a combination of both (0.005+20 mg/gland); the combination significantly ($p<0.05$) reduced bacterial counts in infected glands [Diarra 2013].

In BALB-c mice, intranasal instillation with a highly infective oropharyngeal *E. coli* strain resulted in 59.2% mortality after 48 hours. Mortality caused by the same strain pre-cultured with a dry extract (180 mg/mL PACs) was significantly ($p<0.01$) lower at 18.5%, and deaths occurred only during the first 24 hours due to increased bacterial clearance accompanied by a decreased inflammatory immune response and pulmonary neutrophil recruitment. Profuse neutrophil infiltration and severe alveolitis was observed in lungs challenged with non-exposed *E. coli*, whereas lung injury was significantly ($p<0.05$) attenuated in mice challenged with PAC-exposed *E. coli* [Margetis 2015].

Effects on drug metabolising enzymes
Male Wistar rats were treated orally with a standardized extract (containing 1.6 mg of anthocyanidins and 36 mg of PACs) in two dosage schemes (long-term: 14 days, 0.5 mg PACs/kg/d; short-term: 1 day, 1.5 mg PACs/kg). Long-term administration showed significantly ($p<0.05$) increased activities of hepatic CYP3A and CYP1A1 (by 38% and 34% respectively). Both treatments significantly ($p<0.05$) enhanced hepatic carbonyl reductase 1, UDP-glucuronosyl transferase and glutathione-S-transferase activities. No change in the activity of these enzymes was observed in the small intestine [Bartikova 2014].

Other effects
Male Wistar rats received a 90% methanolic extract from lyophilized cranberries (100 mg/kg p.o. for 10 days) and were challenged with doxorubicin (DOX; 15 mg/kg i.p. on day 7). DOX-induced bradycardia, ST segment depression and prolongation of ST and QT intervals in ECG were completely restored by the extract ($p<0.05$). The extract significantly inhibited DOX-provoked elevated myeloperoxidase activity, GSH depletion as well as accumulation of GSSG, MDA and protein carbonyls in cardiac tissues ($p<0.05$). The DOX-induced decreases of cardiac activities of SOD, glutathione peroxidase (GSH-Px) and glutathione reductase (GR) were significantly ($p<0.05$) improved. Treatment with the extract significantly ($p<0.05$) reduced the DOX-induced rise of serum LDH, creatine phosphokinase, creatine kinase-MB and troponin I level. Histopathological changes in cardiac tissues were also improved [Elberry 2010].

Unfit mares completed three graded exercise tests (GXTs) in a cross-over design after receiving either water (2 L) or cranberry extract (30 g in 2 L of water) 1 hour prior to testing with 7 days wash-out. Blood samples were taken prior to dosing (pre-exercise), at the end of each step of the GXT, at the end of the exercise and at 2, 5 and 30 min, 1, 2, 4 and 24 h post-GXT. No effect of treatment was observed on maximal oxygen uptake, run-time to fatigue, core temperature, total blood protein or haematocrit. The cranberry group had significantly ($p<0.05$) lower TNF-α mRNA expression than control [Liburt 2010].

A water-soluble cranberry extract (4.0% PACs) at 2 mg/mL enhanced innate immunity of *C. elegans* against *Vibrio cholerae* infection as shown by an elongation of survival time. Supplementation only slightly reduced the intestinal colonization of *V. cholerae*, but upregulated the expression of innate immune genes, such as clec-46, clec-71, fmo-2, pqn-5 and C23G10.1. In *C. elegans* mutants p38 MAPK signalling, insulin/IGF-1 signalling and HSF-1 were shown to be involved in the host immune response to the extract [Dinh 2014].

Male albino Wistar rats were intoxicated with CCl_4 (1.6 g/kg b.w. s.c., twice a week for 30 days). During this period one group was treated intragastrically with 7 mg/kg of a cranberry extract enriched in phenolics. The extract prevented changes in liver mitochondrial ultrastructure. The number of damaged mitochondria/100 mitochondria was 10.9 in untreated controls, 17.7 in intoxicated controls and 13.8 in the extract group ($p<0.05$ as compared to CCl_4 group) [Lapshina 2015].

Sprague-Dawley rats infected in the mouth with *Streptococcus mutans* consumed 56% sucrose with their feed and 5% sucrose with the drinking water. Topical treatment with a PAC fraction twice daily for 5 weeks led to the incidence and severity of smooth-surface caries being significantly reduced in the PAC group as compared with vehicle control, and 40-45% less severe smooth-surface lesions of dentin were observed (both $p<0.05$). The influence on the incidence and severity of sulcal-surface caries (at the dentin exposed level) was less [Koo 2010].

In a mouse model, oral administration of bovine reovirus type 3 resulted in systemic haemorrhage, diarrhoea and dehydration. Deaths occurred 3 to 4 days after inoculation. Co-inoculation of the virus with a 40% concentration cranberry juice cocktail (0.2 ml by gavage) revealed normal mucosa in the colon, intact goblet cells and dense faeces on histological analsysis [Lipson 2010].

Experimental periodontitis in female BALB-c mice induced by mixed infection with *Porphyromonas gingivalis* and *Fusobacterium nucleatum* resulted in distinct alveolar bone loss after 42 days, which was significantly ($p<0.05$) less after pretreatment of the two strains with NDM (MG > 12.000) from cranberry juice added to the drinking water [Polak 2013].

Pharmacological studies in humans

Anti-adherence activity
Following consumption of 140 mL of cranberry juice, urine samples from 15 out of 22 healthy volunteers showed significant ($p<0.05$) inhibition of adherence of a clinical isolate of *E. coli* to uroepithelial cells [Sobota 1984].

Isolates of *E. coli*, *Proteus* and *Pseudomonas* from patients with urinary tract infections (UTIs), were tested for adherence to urinary epithelial cells by four different techniques with a cranberry juice cocktail (CJC): pre-incubation of the bacteria with CJC; pre-incubation of the urinary epithelial cells with CJC; pre-incubation of the bacteria with urine collected from healthy individuals 2 hours after drinking 340 mL of CJC; and use of urinary epithelial cells collected from healthy individuals 2 hours after drinking CJC. Significant ($p<0.05$) anti-adherence activity of cranberry was demonstrated by each technique [Schmidt 1988].

In an open, controlled study 39 uropathogenic P-fimbriated *E. coli* isolates obtained from women with UTIs were incubated with urine collected from healthy women over a 12-hour period before and after consumption of 240 mL of a CJC. Urine collected after CJC consumption prevented adhesion of 80% of the 39 *E. coli* isolates and 79% of the 24 antibiotic-resistant isolates, while pre-consumption urine failed to prevent adhesion of any of the isolates. Anti-adherence activity was evident in the urine within 2 hours and for up to 10 hours after CJC consumption [Howell 2002].

In a double-blind, placebo-controlled, cross-over study 20 healthy volunteers were randomized to receive on separate occasions, with a wash-out period of at least 6 days, a single dose of 250 mL or 750 mL of a cranberry drink (containing 27% of cranberry juice concentrate) or a placebo drink. Compared to urine samples from the placebo group, urine collected the morning after consumption of the cranberry drink significantly and dose-dependently inhibited adherence of six uropathogenic *E. coli* strains from patients with UTIs to a human urinary epithelial bladder cell line [Di Martino 2006].

Eight volunteers consumed a preparation (36 or 108 mg cranberry) or placebo in a double-blind, randomised, cross-over trial with a wash-out period of at least 6 days between each regimen. Twelve hours after consumption, the first morning urine was collected, and four different *E. coli* strains were cultured in the samples. A significant ($p <0.001$) dose-dependent decrease in bacterial adherence of all strains to human T24 epithelial cells was seen after both doses of cranberry as compared to placebo [Lavigne 2008].

Urine of healthy women who had ingested cranberry extract (not further specified) significantly ($p<0.0001$) reduced the bacterial adhesiveness of two strains of *E. coli* (ATCC 25922, ATCC 35218) to HT1376 human bladder carcinoma cells (-50.9%). No changes were observed with placebo [Tempera 2010].

In a multi-centre, randomized, double-blind, placebo-controlled, cross-over study, 32 women consumed cranberry powder standardized to 18, 36 or 72 mg PACs or placebo. Urine samples collected from 1 to 6 hours as well as at 24 hours after consumption were tested for anti-adhesion activity in a mannose-resistant haemagglutination assay and with uropathogenic *E. coli* on human T24 epithelial cells. Significant ($p<0.001$) anti-adhesion activity was observed in the cranberry groups as compared to placebo. The inhibition dose-dependently increased with PAC equivalents and was prolonged until 24 h with 72 mg of PAC [Howell 2010].

Four male volunteers took 300 mg of a cranberry dry extract (50% ethanol soluble) twice daily for 7 days, with urine samples collected prior to and on days 3 and 7 of consumption. A significant reduction of the adhesion of a uropathogenic *E. coli* strain to T24 bladder cells was observed ($p<0.01$ at both time points) [Rafsanjany 2015].

After consumption of a single dose of cranberry juice cocktail (470 mL containing 0.04% PACs) or placebo by 12 healthy participants, in a cross-over study with a washout period of 1 week, urine was collected at 0, 0 to 3, 3 to 6, 6 to 9, 9 to 12, and 24 hours after consumption. The juice significantly ($p<0.05$) increased the anti-adhesion activity of uroepithelial cells against P-fimbriated *E. coli* compared with placebo [Mathison 2014].

In a similar randomized, double-blind, placebo-controlled, cross-over set-up, 10 volunteers ingested single doses of 450 mL of cranberry beverages or placebo. In a second experiment, 60 participants took two doses of the beverages, in the evening and the following morning. Urine samples were taken at baseline and 0–3, 3–6, 6–9 and 24 hours, and from 0 to 6 hours post-intervention, respectively. The mean anti-adhesion activity, as determined by the suppression of agglutination of mannose-resistant human red blood cells, following incubation with uropathogenic P-fimbriated *E. coli* was significantly ($p<0.05$) higher in cranberry groups as compared to placebo [Kaspar 2015].

In a prospective study, 72 patients with recurrent UTIs were randomized to take either cranberry capsules (2 x 60 mg PACs/d; n=36) or Lactobacillus capsules (2 x 400 million bacteria/d) as 'placebo' for 12 weeks. Compared to 'placebo', cranberry significantly reduced the urinary mean bacterial adhesion score (0.28 vs. 2.14; $p<0.001$) and biofilm formation ($p<0.01$) [Singh 2016].

After ingestion of 360 mg of extract (42.6% A-type PACs and 14.6% B-type PACs) and 200 mg of quercetin by healthy volunteers, urine samples were collected after 2 ,4, 6, 8 and 24 h. Changes in antiadhesive properties of uropathogenic E. coli to HAT-29 epithelial cells after treatment with the urine samples were strongest ($p<0.001$) in urine samples taken at 6–8 h. Metabolomic analysis revealed valeric acid- and valerolactone-derivatives in these samples [Peron 2017b].

Antimicrobial activity of urine

In a crossover study, 8 healthy volunteers received three successive regimens with a minimum 6 day wash-out period. Volunteers received with their evening meal either 3 capsules of cranberry PACS (36 mg each), 3 placebo capsules or 1 cranberry and 2 placebo capsules. Urine samples were taken 12 hours later (first urine of the day). A *C. elegans* model was used to evaluate the influence of the urine following cranberry intake on the ability of 4 different uropathogenic *E. coli* strains to kill the worms. Urine collected after intake of 108 mg cranberry PACs resulted in reduced mortality of the worms feeding on 3 of the *E. coli* strains. The effects were significant in 2 strains with type 1 pili and P-fimbriae ($p<0.001$) and another strain with type 1 pili but no P-fimbriae ($p=0.02$) as compared to the placebo-treated *E. coli* strains [Lavigne 2008].

A similar assay was used to evaluate the influence of urine following intake of cranberry powder standardized to 18, 36 and 72 mg PACs on the virulence of a uropathogenic *E. coli* strain. Pre-treatment of the bacteria with the urine of patients who took the cranberry preparations reduced the ability to kill worms as compared to untreated *E. coli*. The effect was most pronounced with 72 mg of PACs [Howell 2010].

Effects on urinary stone risk factors

Calcium oxalate is the most common type of urinary stone. In dietary excess, oxalate can be a causative factor in nephrolithiasis; cranberry juice contains moderately high levels. Urine samples collected from 5 healthy volunteers before and after taking the recommended dosage of cranberry concentrate tablets for one

week were analysed for oxalate and other components. Average oxalate levels in the urine were significantly ($p<0.01$) increased by 43.4%, from 29.0 to 41.2 mg/day over the 1-week period. While urinary pH dropped from 5.82 to 5.54 (not significant) and urinary calcium increased by 12.8% (not significant). On the other hand, there were significant increases in urinary levels of the stone formation inhibitors magnesium (+ 47.3%, $p<0.02$) and potassium (+ 67.5%, $p<0.006$) [Terris 2001].

In two other cross-over studies [Keßler 2002, Gettman 2005], involving daily intake of cranberry juice preparations, urinary excretion of oxalate also increased. On the other hand, in a further cross-over study, involving 20 healthy men, daily consumption of 500 mL of cranberry juice significantly ($p<0.001$) reduced urinary excretion of oxalate [McHarg 2003]. This contradiction reflects the complexity of the processes demonstrated by Terris, and other effects that may minimise the risk of urinary stone formation [Gettman 2005].

In a cross-over study on the effect of fruit juices on risk factors associated with kidney stone formation, 12 healthy male subjects adhered to a standard diet (including beverages) for 5 days during each of four study phases. On the fifth day in each phase they consumed 330 mL of juice (cranberry or plum or blackcurrant) diluted to 750 mL with mineral water or, as the control, 750 mL of mineral water. Compared to the control, cranberry juice significantly lowered the urinary pH from 6.35 to 6.18 ($p\leq0.05$) and increased the excretion of oxalic acid ($p\leq0.05$). Uric acid excretion was unchanged, but the "relative supersaturation value" for uric acid increased from 0.67 to 0.99 ($p\leq0.05$), which could increase the risk of uric acid stone formation [Keßler 2002].

In a further cross-over study, 20 healthy male students without previous history of kidney stones were randomized to receive daily for 2 weeks either 500 mL of cranberry juice (oxalate 86 mg/L, ascorbic acid 300 mg/L) diluted with 1500 mL water, or 2000 mL water only as control, and after a 2-week wash-out the alternative treatment. Analysis of urine samples collected at baseline and on day 14 of each phase revealed that cranberry juice significantly reduced the excretion of oxalate ($p<0.001$) and phosphate ($p<0.014$), and increased citrate excretion ($p = 0.001$) as compared to the control [McHarg 2003].

Healthy subjects (n=12) and calcium oxalate stone formers (n=12) were randomized in a cross-over study to receive a controlled metabolic diet and either 1 litre cranberry juice cocktail (CJC, 27% cranberry juice) or 1 litre deionized water daily for 7 days and, after a 3-week wash-out, the alternative treatment. Blood samples and 24-hour urine collections on the last 2 days of each phase were analysed for stone risk factors and serum chemistry. Since no significant differences were evident between normal subjects and stone formers in response to the CJC the groups were combined. Cranberry juice significantly increased urinary calcium (from 154 to 177 mg/day, $p = 0.0008$) and urinary oxalate (from 26.4 to 29.2 mg/day, $p = 0.04$), while urinary uric acid decreased (from 544 to 442 mg/day, $p<0.0001$), and urinary pH dropped from 5.97 to 5.67 ($p = 0.0005$). Although cranberry juice had a mixed effect, the authors concluded that overall it probably does not substantially affect the risk of stone formation [Gettman 2005].

Antioxidant and anti-inflammatory activity
The effect of cranberry consumption on plasma antioxidant capacity was evaluated in 9 healthy female volunteers. After an overnight fast they consumed with wash-out periods of one week, 500 mL of cranberry juice or 500 mL of a 9% sucrose solution. Blood samples were collected 5 minutes before and 0.5, 1, 2 and 4 hours after intake of the beverage. Consumption of the juice, resulted in a significant increase in plasma antioxidant capacity ($p<0.001$), mainly attributable to an increase in plasma vitamin C concentration ($p<0.001$) rather than a modest increase in total phenolics ($p<0.05$ after 1 hour) [Pedersen 2000].

In 20 healthy female volunteers, consumption of 750 mL/day of cranberry juice for 2 weeks did not alter blood or cellular antioxidant status or biomarkers of lipid status pertinent to heart disease as compared to placebo or baseline. The juice had no effect on basal or induced oxidative DNA damage [Duthie 2006].

After a single dose (240 mL) of high fructose corn syrup (HFCS) or the syrup supplemented with cranberry juice, plasma antioxidant capacity, glucose, triglycerides and ascorbate were measured 6 times over 7 hours in 10 normal volunteers. The decrease in plasma antioxidant capacity after HFCS at all time points was improved with cranberry juice [Vinson 2008].

In a randomized, double-blind, placebo-controlled, cross-over trial, 12 participants consumed a single dose of cranberry juice cocktail or placebo with a washout period of 1 week. Blood was collected at 0, 2, 4, 8, and 24 hours after consumption. The juice significantly ($p<0.05$) increased GSH concentrations and SOD activity compared with placebo at 24 hours. No significant differences were observed in GSSG, GSH:GSSG ratio, CRP, NO production and oxidative damage of DNA. IL-4 was significantly ($p<0.05$) reduced after 4 hours whereas other cytokines remained unchanged [Mathison 2014].

In a double-blind, randomized, placebo-controlled study, 16 male members of a rowing team received two capsules per day for 6 weeks of either cranberry extract (n=9) or placebo (n=7). Each cranberry capsule contained 360 mg of cranberry extract (10% PACs; equivalent to 4320 mg cranberry fruit). The participants performed a 2000 m rowing test at the beginning and at the end of the supplementation. Blood samples were taken prior to each exercise test, one minute after the test, and after a 24-h recovery period. The levels of hepcidin, IL-6, TNF-alpha, ferritin, iron, soluble transferrin receptor and myoglobin were determined, along with total iron-binding capacity, unbound iron-binding capacity and total antioxidant capacity (TAC). At the end of the study period, athletes in the cranberry group had significantly higher resting, post-exercise and post-recovery levels of TAC than controls [Skarpanska-Stejnborn 2017].

Overweight or obese volunteers (n=78; BMI 27–35) ingested 450 mL of a low calorie, high polyphenol cranberry extract beverage or placebo daily for 8 weeks in a randomized, double-blind, placebo-controlled trial. Blood and urine samples were collected at baseline and after 8 weeks. Compared to placebo, a single cranberry dose at baseline lowered endothelin-1 and elevated NO, the GSH:GSSG ratio and interferon-γ ($p<0.05$). After 8 weeks of cranberry intervention, fasting C-reactive protein was significantly ($p<0.05$) lower as compared to placebo. No effects on any other inflammatory biomarkers were seen [Chew 2019].

Investigations on possible interactions
A number of cases of suspected interaction between cranberry consumption and the anticoagulant warfarin have been reported since 1999 [UK Medicines and Healthcare Products Regulatory Agency 2003, 2004, Suvarna 2003, Zikria 2010, Hamann 2011, Haber 2012]. From assessment of the data available in several reports none of the cases was considered to plausibly demonstrate that loss of anticoagulant control was caused by cranberry juice [Bussey 2006, Greenblatt 2006a,b]. Additionally, in several case reports excessive amounts of juice or sauce were ingested (0.4-2 L/d for 1 week to 1 month) [Zikria 2010, Haber 2012].

In a study investigating the effect of cranberry juice on CYP2C9, the NSAID flurbiprofen was used as a surrogate for S-warfarin, since both drugs are metabolized almost exclusively by CYP2C9. In human volunteers, clearance of a single 100 mg dose of flurbiprofen was not significantly changed by 230 mL of cranberry juice administered the night before and 30 minutes before the flurbiprofen [Greenblatt 2006b].

In an open, randomized, 3-way cross-over study, 12 healthy male volunteers received single oral 200 mg doses of cyclosporine (as surrogate for R-warfarin), with either 240 mL of cranberry juice or water, under fasting conditions and multiple whole blood samples collected up to 36 hours. The juice had no significant effect on the overall disposition of cyclosporine, the ratios of least squares means for AUC_t, AUC_{inf}, and C_{max} for cyclosporine were 95.0%, 93.4%, and 95.2% respectively [Grenier 2006].

In another study, 10 healthy volunteers took 3 × 200 mL of cranberry juice or water daily for 10 days. On day 5 they ingested simultaneously 10 mg of racemic warfarin, 1 mg of tizanidine and 0.5 mg of midazolam as probe drugs for CYP2C9, CYP1A2 and CYP3A4 enzymes respectively. The juice did not change the anticoagulant effect of warfarin nor inhibit the activities of CYP2C9, CYP1A2 or CYP3A4 [Lilja 2007].

The effect of cranberry juice on prothrombin time, as assessed by the international normalized ratio (INR), was investigated in a randomized, double-blind study. Seven patients with atrial fibrillation, on a stable dose of warfarin for 3 months, were randomized to consume 250 mL of cranberry juice daily for 7 days then, after a wash-out period of 7 days, placebo for 7 days, or vice versa. No significant interaction between cranberry juice and warfarin was evident; the INR did not change significantly from baseline and differences between the cranberry and placebo groups were not significant [Li 2006].

In a randomized, double-blind study, patients on warfarin with a history of stable anticoagulation were given 230 mL/d of cranberry juice (n = 14) or placebo (n = 16) for 2 weeks. Daily intake of cranberry juice by patients on warfarin therapy appeared to have no significant effect on the INR compared to placebo [Ansell 2008].

A randomized, open-label, cross-over study demonstrated that although cranberry did not alter warfarin *pharmacokinetics* or plasma protein binding it could alter the *pharmacodynamics* of warfarin in certain individuals, depending on genetic factors. Variability in warfarin response has been attributed by some authors to genetic variability of *CYP2C9** (cytochrome P450 2C9) and *VKORC1* (vitamin K epoxide reductase subunit 1) genes. The study involved healthy male subjects of known, varying genotype with respect to *CYP2C9* and *VKORC1*. From 16 subjects randomized to one of three treatments, 12 completed the study (4 per treatment arm). The volunteers received a single high dose of 25 mg of racemic warfarin orally either alone or after 2 weeks of pretreatment with cranberry juice concentrate in capsules (2 × 500 mg three times daily, corresponding to 57 g fresh fruit per day) or garlic tablets. Administration of the cranberry or garlic preparations continued for a further 7 days when the last blood sample was drawn. Following a wash-out period of 2 weeks, the subjects crossed over to the other treatments.

Cranberry increased the INR AUC by 30%. The mean INR_{max} attained after warfarin and cranberry was 2.8 compared to 2.6 after warfarin alone [Mohammed Abdul 2008].

In an open, cross-over study with a wash-out period of at least 2 weeks, 8 healthy volunteers were given in one phase a single 25 mg diclofenac tablet with 180 mL of water and in the other phase pretreated for 5 days with 180 mL cranberry juice drink (containing 27% cranberry) twice a day and on day 6 administered a 25 mg diclofenac tablet and a further 180 mL cranberry juice. No significant differences were observed in t_{max}, C_{max} or AUC0-∞ of diclofenac following cranberry consumption [Ushijima 2009].

Possible interactions between amoxicillin or cefaclor and consumption of cranberry juice were investigated in 18 healthy women receiving a single oral dose of amoxicillin (500 mg and 2 g) with or without 240 mL of cranberry juice cocktail in a cross-over design. Another test was conducted with 500 mg cefaclor with or without 360 mL cranberry juice cocktail. Concurrent use of cranberry juice had no significant effects on the extent of oral absorption or renal clearance of amoxicillin and cefaclor. However, T_{max} of amoxicillin was significantly higher with the juice (0.75 hours with 500 mg and 1 hours with 2 g; $p<0.01$). For cefaclor a significant decrease in C_{max} ($p< 0.01$) and a longer T_{max} ($p< 0.05$), but no difference in the mean AUC with concomitant use of cranberry juice was observed [Li 2009].

Healthy volunteers (n=16) received every 15 minutes 3 x 240 mL of a concentrated juice or water and 5 mg midazolam with the third portion. Ten blood samples were taken during the 12 hours after the last dose. As compared to water, the concentrate significantly increased the geometric mean AUC0-∞ of midazolam by 30% ($p<0.001$), decreased the geometric mean AUC0-∞ ratio of 1´-hydroxymidazolam/midazolam by 40% ($p<0.001$) and had no effect on geometric mean terminal half-life. This indicated inhibition of enteric, but not hepatic CYP3A-mediated first-pass metabolism of midazolam [Ngo 2009].

In a similar study, 16 volunteers followed the same administration scheme of cranberry concentrate, but took 10 mg warfarin and 10 mg vitamin K concomitantly with the last dose of concentrate. Relative to water, the juice decreased the geometric mean S-to-R-warfarin Cmax ratio significantly ($p<0.05$) by 11%. No significant differences were detected between water and the concentrate with respect to the geometric mean AUC0–∞ ratio and terminal half-life of S/R-warfarin [Ngo 2010].

In a randomized, double-blind, placebo-controlled trial, 30 patients on stable warfarin anticoagulation consumed 240 mL cranberry juice cocktail (n=14) or 240 mL placebo beverage (n=16) daily for 2 weeks. INR values and plasma levels of R- and S-warfarin were measured during the intervention and a 1-week follow-up period. The groups did not differ significantly in mean plasma R- and S-warfarin concentrations. Four patients in each group developed minimally elevated INR (3.38-4.52) during the treatment period. Mean INR differed significantly ($p<0.02$) only on treatment day 12 [Ansell 2009].

Ten patients on stable warfarin therapy received 240 mL of cranberry juice twice daily for 7 days. No differences in the mean prothrombin time between baseline and at days 2, 6 and 8 were observed [Mellen 2010].

Other effects

A randomized, double-blind, placebo-controlled intervention in 45 healthy volunteers compared a low calorie cranberry beverage (CB; 450 mL/d; n = 22) with a placebo beverage (PB; n = 23) for 10 weeks on health outcomes related to cold and influenza symptoms. A significant ($p<0.001$) increase in the proliferation index of γδ-T cells *ex vivo* was observed in the CB group as compared to placebo. The total incidence of colds and

* As a convention, these designations are italicised when referring to genes (CYP2C9 is the gene that encodes the enzyme CYP2C9).

influenza did not differ between the groups, but the proportion of the total number of symptoms was significantly (p = 0.031) lower in the CB group. Levels of cytokines (IL-1α, IL-1β, IL-13, MIP-1β, TNF-α) in peripheral blood mononuclear cell did not differ between the groups, but IFN-γ was significantly higher in the CB group [Nantz 2013].

In a randomized, double-blind, controlled, cross-over trial, flow-mediated dilation (FMD), blood pressure, pulse wave velocity and augmentation index were investigated in ten healthy males at baseline, 1, 2, 4, 6 and 8 h post-consumption of cranberry juices containing 409, 787, 1238, 1534, and 1910 mg of total cranberry (poly)phenols (TCP), or a control drink. Dose-dependent increases in FMD were observed at all time-points with a peak at 4 h and maximal effects with 1238 mg TCP. No significant changes were seen in blood pressure, pulse wave velocity and augmentation [Rodriguez-Mateos 2016].

Urine and faecal samples were collected from 10 healthy individuals before and at the end of intake of 42 g/d of sweetened dried cranberries for 2 weeks. In the urinary proteome, 22 proteins changed significantly (p<0.05) from pre- to post-samples. Of 25 proteins found in all subjects, the vesicular integral membrane protein, the phosphoinositide 3-kinase interacting protein 1 and uromodulin significantly decreased (p=0.001). Changes in the faecal microbiome were a decrease in the *Firmicutes:Bacteroidetes* ratio in 7 of 10 volunteers, an increase in *Akkermansia* bacteria, increases in commensal bacteria and decreases or the absence of bacteria associated with negative health effects [Bekiares 2018].

Overweight or obese volunteers (n=78; BMI 27–35) underwent 3 oral glucose tolerance challenges (prior to intervention, after a single dose of verum or placebo in week 0 and in week 8) during a randomized, double-blind, placebo-controlled trial. The participants ingested 450 mL/d of a low calorie, high polyphenol cranberry extract beverage or placebo for 8 weeks. Blood and urine samples were collected at baseline, after 8 weeks and during the challenges. The cranberry beverage significantly (p<0.05) reduced serum insulin and increased HDL cholesterol compared to placebo [Chew 2019].

High-molecular-weight NDM (MW <12000) from cranberry juice concentrate in a mouthwash (3 mg/mL) was evaluated by colonization of 40 children with *Streptococcus mutans*. The children rinsed their mouth one minute daily for 30 days with 5 mL of the preparation or a placebo solution. The mean plaque and salivary scores after 30 days were significantly decreased with the preparation (p<0.0001 for both scores as compared to baseline; p<0.008 and 0.007, respectively, as compared to placebo) [Gupta 2015].

Epidemiological data
An evaluation of US data for adults (n=10334) showed significantly (p<0.015) lower levels of C-reactive protein for consumers of cranberry juice cocktails (average consumption 404 mL/2 days) and trends towards lower weight and waist circumferences, levels of BMI, fasting glucose, insulin, total cholesterol and triglyceride values [Duffey and Sutherland 2015].

Clinical studies

See Table 1 for a brief summary of clinical studies.

Prevention of bacteriuria and symptomatic urinary tract infections (UTIs)

In a randomized, double-blind, placebo-controlled study, 153 volunteers (women; mean age 78.5 years) were randomized to 300 mL of a commercial cranberry beverage or a placebo drink daily for 6 months. Urine samples were tested at baseline and at monthly intervals for 6 months for bacteriuria and white blood cells (an indication of pyuria). For subjects in the cranberry group, the odds of bacteriuria ($\geq 10^5$ organisms/mL) with pyuria were only 42% of the odds in the placebo group (p = 0.004) and, for those with bacteriuria-pyuria in the previous month, the odds of remaining so were only 27% of the odds in the placebo group (p = 0.006) [Avorn 1994].

In a randomized, double-blind, placebo-controlled cross-over study, women (28-44 years) with a history of recurring UTIs and with a symptomatic UTI treated with antibiotics on commencement were randomly assigned to one of two groups. Treatment began with either 400 mg of a cranberry extract or placebo daily for 3 months, followed by the alternative treatment for a further 3 months. Out of 19 subjects, 10 completed the study (4 taking cranberry first, 6 placebo first) and among these 10 a total of 21 UTIs were recorded, only 2 being for non-*E. coli* bacteria. Cranberry was significantly (p<0.005) more effective than placebo in reducing the occurrence of UTIs; only 6 occurred during the 3 months of cranberry treatment compared to 15 during 3 months on placebo [Walker 1997].

To compare cranberry extract with low-dose trimethoprim for prevention of recurrent UTIs, women aged 45-93 years with two or more antibiotic-treated UTIs in the previous 12 months were randomized to 500 mg cranberry extract (not further specified; n = 69) or 100 mg of trimethoprim (n = 68) daily for 6 months. Antibiotic-treated UTIs were experienced by 39 of the 137 participants, with no significant difference between the numbers in each group (25 in the cranberry group, 14 in the trimethoprim group) or the median times to first recurrence (84.5 days in the cranberry group, 91 days in the trimethoprim group [McMurdo 2009].

A double-blind, non-inferiority trial compared 12-months of prophylactic treatment with 480 mg trimethoprim-sulfamethoxazole (TMP-SMX) or 2 x 500 mg cranberry extract daily in premenopausal women with recurrent UTIs (n=221). After 12 months, the mean number of patients and the proportion of patients with at least 1 symptomatic UTI was higher in the cranberry group than in the TMP-SMX group (4.0 vs. 1.8; p=0.02) and 78.2% vs. 71.1%, respectively. Median time to the first UTI was 4 months for the cranberry group and 8 months for the TMP-SMX group. After 1 month, in the cranberry group, 23.7% of faecal and 28.1% of asymptomatic bacteriuria *E.coli* isolates were TMP-SMX resistant, whereas in the TMP-SMX group, 86.3% of faecal and 90.5% of asymptomatic bacteriuria *E. coli* isolates were TMP-SMX resistant [Beerepoot 2011].

A controlled, double-blind trial was conducted in children with recurrent UTIs, 85 were aged 1 month to 1 year and 107 were aged from 1 to 13 years. As prophylaxis, the children received 0.2 mL/kg of a syrup containing 3% cranberry extract (n=117) or 0.2 mL/kg of a syrup containing 8 mg/mL trimethoprim (n=75) for one year. The cumulative rate of UTIs in infants treated with trimethoprim was 28% as compared to 35% with cranberry. In children over 1 year the rate was 35% with trimethoprim and 26% with cranberry [Fernández-Puentes 2015, Uberos 2015].

To evaluate the effectiveness of cranberry in the prophylaxis of UTIs, 150 women (21-72 years) were randomized to one of three treatments for a year (n = 50/group): cranberry juice + placebo tablets, placebo juice + cranberry tablets (not further specified), or placebo juice + placebo tablets. Tablets were taken twice daily, 250 mL of juice three times daily. All the subjects had experienced at least two UTIs during the previous year. The number of patients experiencing at least one symptomatic UTI

per year decreased significantly in both the cranberry juice and cranberry tablet groups (both $p<0.05$), to 10 patients (20%) and 9 patients (18%) respectively, compared to 16 patients (32%) in the placebo group [Stothers 2002].

In a randomized, double-blind, placebo-controlled study 376 elderly, hospitalized patients (mean age 81 years) were administered 300 mL of cranberry juice daily (n = 187) or placebo (n = 189) and followed up for 35 days or until hospital discharge. A total of 21 out of 376 participants (5.6%) developed a symptomatic UTI, 7/187 in the cranberry juice group and 14/189 in the placebo group. As a secondary outcome, there were significantly ($p = 0.027$) fewer infections with *E. coli* in the cranberry group [McMurdo 2005].

The effects of cranberry on asymptomatic bacteriuria in pregnancy were assessed in a double-blind, placebo-controlled study in 188 women at less than 16 weeks of gestation. The women were randomized to a 240 mL cranberry juice cocktail (CJC; 27% cranberry juice) three times daily (group A), CJC at breakfast then placebo at lunch and dinner (group B), or placebo three times daily (group C). Of the 188 women randomized, 73 withdrew (mainly due to gastrointestinal upset). In all there were 27 UTIs in 18 of the women, of which 6 were in 4 of the group A women, 10 in 7 of the group B women and 11 in 7 of the group C women. There were reductions in the frequency of asymptomatic bacteriuria and all UTIs, by 57% and 41% respectively, in women who took multiple daily doses of CJC when compared to placebo only [Wing 2008].

In a randomized, double-blind, placebo-controlled trial, 319 women with acute UTI received 240 mL of a low-calorie cocktail containing 27% cranberry juice (112 mg PACs per dose) or placebo twice daily for 6 months. Participants were followed up until a second UTI or for 6 months. An overall recurrence rate of 16.9% (20% for verum and 14% for placebo) with no significant difference between the groups was found [Barbosa-Cesnik 2011].

In a randomized, double-blind, placebo-controlled trial, children (n=255; mean age 4 years) treated for UTI were randomized to either cranberry juice (n=129) or placebo (n=134) for 6 months. Twenty children (16%) in the cranberry group and 28 (22%) in the placebo group had at least 1 recurrence of UTI, with no differences in timing between the first recurrences. Episodes of UTI were 27 and 47 in the cranberry and placebo groups, respectively, and the UTI incidence density per person-year at risk was 0.16 episodes lower in the cranberry group ($p=0.035$). The children in the cranberry group had significantly ($p<0.001$) fewer days on antibiotics [Salo 2012].

Children (n=40; 5 to 18 years; at least two non-febrile UTIs in the year before) were randomized to either 2 mL/kg/day juice containing 37% PACs (verum) or the same amount without PACs (placebo) for one year in a double-blind study. In the verum group, 5 UTIs occurred in 5 patients as compared to 15 UTIs in 8 patients in the placebo group. In the 13 and 14 patients who completed the study, respectively, an average incidence of UTIs of 0.4/patient after verum and 1.5/patient after placebo ($p=0.045$) was observed [Afshar 2012].

A randomized, double-blind, placebo-controlled study involved 213 patients suffering from multiple UTI relapses. Patients consumed either 125 mL cranberry juice (40 mg PACs/dose; n=107) or a placebo beverage (n=106) once daily for 24 weeks. Only in the subgroup of females above 50 years was a significantly ($p = 0.0425$) lower rate of relapse of UTIs between groups observed [Takahashi 2013].

In a prospective, randomized, double-blind, placebo-controlled study, 171 multiple sclerosis outpatients with urinary disorders (pollakiuria, urgency, dysuria and/or urinary incontinence) received either cranberry powder for oral solution (18 mg PACs) twice daily or placebo for 1 year. No differences in the time to the first symptomatic UTI across the year, the 1-year UTI rate and the number of UTIs in each patient were observed between the groups [Gallien 2014].

Long-term care facility residents (n=928, mean age 84) with different UTI risk at baseline received cranberry capsules (500 mg preparation; 9 mg PACs) twice daily for 12 months or placebo in a double-blind, randomized, multicentre trial. In participants with high UTI risk at baseline (n = 516), the incidence of UTI was significantly ($p=0.04$) lower with verum (n=253) than with placebo (n=263). No difference in UTI incidence between cranberry (n=205) and placebo (n=207) was found in participants with low UTI risk (n = 412) [Caljouw 2014].

Patients undergoing eligible gynaecological surgery (n=160) were enrolled in a randomized, double-blind, placebo-controlled trial on the efficacy of cranberry in preventing UTIs after surgery with catheter placement. The participants received 2 cranberry capsules (each equivalent to 236 mL juice) or placebo twice daily for 6 weeks after surgery. The occurrence of UTIs was significantly ($p<0.008$) lower in the cranberry group compared with placebo [Foxman 2015].

Women with a history of UTIs (n=182) were administered for 6 months either 2 x 250 mg/d cranberry powder capsules (0.56% PACs; n=89) or placebo capsules (n = 93) in a randomized, double-blind, placebo-controlled trial. The number of UTIs during the observation period was significantly lower in the cranberry group (10.84%) compared to placebo (25.81%) and the time to the first UTI significantly longer (both $p= 0.04$) [Vostalova 2015].

A randomized, double-blind, placebo-controlled trial compared the effects of cranberry in 55 uncircumcised boys and 12 circumcised boys with histories of uncomplicated UTI. The uncircumcised boys were divided into group 1 (n = 28) taking 120 mL/d cranberry juice and group 2 (n = 27) taking placebo juice for 6 months. The circumcised boys in group 3 (n=12) also received placebo juice. At the end of treatment, the incidences of bacteriuria, mainly caused by *E. coli*, were 25%, 37% and 33.3% in groups 1, 2 and 3, respectively, significant ($p<0.05$) between group 1 and both other groups [Wan 2016].

The effects of cranberry capsules (36 mg PACs) on bacteriuria with pyuria were studied in a randomized, double-blind, placebo-controlled trial in elderly women (n=185; over 65 years). Patients with or without bacteriuria with pyuria at baseline took 2 capsules/day (equivalent to appr. 600 mL of cranberry juice) or placebo for 1 year. No significant difference in the presence of bacteriuria with pyuria between the treatment group vs. control (29.1% vs. 29.0%) or in the number of symptomatic UTIs (10 in the treatment group vs. 12 in the control group) or other secondary outcomes was observed [Juthani-Mehta 2016].

In a randomized, double-blind, placebo-controlled, multicentre trial, women with a history of a recent UTI were assigned to the intake of 240 mL of a cranberry beverage (119 mg PACs; n = 185) or a placebo beverage (n = 188) daily for 24 weeks. In the cranberry group 39 UTI episodes were observed as compared to 67 episodes in the placebo group ($p=0.016$). Clinical UTI with pyuria was significantly ($p=0.037$) reduced with verum. The time to UTI with culture positivity did not differ significantly between groups [Maki 2016].

In a randomized, double-blind, placebo-controlled trial, 124 men aged over 45 years, with PSA levels <2.5 ng/mL and an IPSS ≥8 received 250 or 500 mg dry cranberry powder or placebo for 6 months. At the end of the trial both cranberry groups showed a dose-dependent effect with significant lowering of the IPSS (–3.1 and –4.1 in the 250- and 500 mg groups, p=0.05 and p<0.001, respectively) compared to placebo (–1.5). Significant differences in the maximum and average urinary flow rate, post-void residual volume and bladder voided volume were observed in the 500 mg group compared to baseline (p<0.018, 0.040, 0.027 and 0.014, respectively) [Vidlar 2016].

In a randomized, placebo-controlled, double-blind study, elderly women with a hip fracture (n=227) were treated with 2 capsules daily of either placebo or cranberry (each containing 550 mg cranberry powder; 4.19 mg PACs), from admission until 5 days postoperatively. No differences were observed between the groups in the propor-tion of patients with hospital-acquired postoperative positive urine cultures [Gunnarsson 2017].

Patients with recurrent UTIs (n=72) were randomized in a prospective study to take cranberry capsules (2 x 60 mg PACs/d; n=36) or *Lactobacillus* capsules (2 x 400 millions bacteria/d) for 12 weeks. A significant (p<0.001) decrease in recurrent UTIs was observed after the cranberry preparation (33%) as compared to the *Lactobacillus* (89%). Mean burning micturition score (0.19 vs. 1.47), microscopic pyuria score (0.36 vs.2.0) and bacterial growth in urine were also significantly reduced (all p< 0.001) [Singh 2016].

One month after discharge following ileal conduit diversion, patients either started to take cranberry extract (n=20; 2 x 400 mg with 1.8% PACs daily) for 3 months, or received training about avoidance of UTIs (n=20), or were left without any intervention (n=20). No significant differences in the groups were observed in UTI symptoms such as increased body temperature, leukocytosis and increased CRP levels. Flank pain score was significantly (p<0.05) lower in the experiment groups (cranberry and training) at weeks 13 to 16. Only one patient in the cranberry group (5%) and 8 patients (40%) in the control group developed urinary tract infections [Temiz 2018].

TABLE 1 CLINICAL STUDIES WITH CRANBERRY PREPARATIONS

First Author Year	Study design	Type of patient No. of patients (test/control)	Daily medication Duration of treatment	Outcome for cranberry group (in comparison with placebo or ref. drug group)
Prevention of bacteriuria and symptomatic urinary tract infections (UTIs)				
Fernández-Puentes 2015	R / D-B comparison with ref. drug	Children 1 month-1 year: 85 Children 1-13 years: 107	0.2 mL/kg syrup with 3% Cranberry extract (n=117) 0.2 mL/kg syrup with 8 mg/mL Trimethoprim (n=75)	In children under 1 year cranberry inferior to trimethoprim. In children over 1 year cranberry not inferior to trimethoprim.
Beerepoot 2011	R / D-B comparison with ref. drug	Women, 23-46 years, with recurrent UTIs: 221 (110/111)	2 x 500 mg Cranberry extract 480 mg Trimethoprim-sulfamethoxazole 12 months	Cranberry extract less effective at prevention of UTIs, but did lead to less resistant E. coli isolates.
McMurdo 2009	R / D-B comparison with ref. drug	Women, 45-93 years, with history of UTIs: 137 (69/68)	500 mg Cranberry extract 100 mg Trimethoprim 6 months	No significant difference between cranberry and trimethoprim in incidence of UTIs or time to recurrence.
Gunnarsson 2017	R / D-B / P-C	Elderly women (mean 83 years) with hip fractures: 144 (75/69)	2 x 550 mg Cranberry powder with 4.19 mg PACs Placebo capsules From admission to 5 days postoperatively	No significant difference in postoperative positive urine cultures.
Maki 2016	R / D-B / P-C	Women (mean 41 years) with recurrent UTIs: 373 (185/188)	240 mL Cranberry drink 240 mL Placebo drink 24 weeks	Significantly less UTIs (p=0.016) and clinical UTIs with pyuria (p=0.037).
Vidlar 2016	R / D-B / P-C	Men (mean 53 years) with PSA levels <2.5 ng/mL and IPSS ≥8: 124 (43/38/41)	250 mg dry Cranberry powder 500 mg dry Cranberry powder Placebo 6 months	Significantly lower IPSS vs. placebo (250 mg p=0.05; 500 mg p<0.001). Significant differences in maximum and average urinary flow rate, post-void residual volume, bladder voided volume (500 mg vs. baseline; p<0.018, 0.040, 0.027 and 0.014, respectively).
Juthani-Mehta 2016	R / D-B / P-C	Elderly women (mean 86.4 years); 185 (92/93)	2 Cranberry capsules with 36 mg PACs 2 Placebo capsules 1 year	No significant differences in bacteriuria with pyuria as well as secondary outcomes.
Wan 2016	R / D-B / P-C	Uncircumcised (55) and circumcised (12) boys, 6 to 18 years, with histories of uncomplicated UTIs: 67 (28/27/12)	120 mL Cranberry juice 120 mL Placebo juice 120 mL Placebo juice 6 months	Significantly lower incidence of bacteriuria in cranberry group as compared to both placebo groups (p<0.05).

Vostolova 2015	R / D-B / P-C	Women (mean 37 years) with recurrent UTIs: 182 (89/93)	2 x 250 mg Cranberry dry fruit capsules with 0.56% PACs 2 x Placebo capsules 6 months	No. of UTI episodes significantly lower and time to the first UTI significantly longer (both p=0.04).
Foxman 2015	R / D-B / P-C	Women, 23-88 years, with eligible gynaecological surgery: 160 (80/80)	2 x 2 Cranberry capsules 2 x 2 placebo capsules 6 weeks	Significantly lower incidence of UTIs) in cranberry group (p=0.008).
Caljouw 2014	R / D-B / P-C	Elderly persons (mean 84 years): 928 High UTI risk: 516 (253/263) Low UTI risk: 412 (205/207)	2 x 500 mg Cranberry capsules with 9 mg PACs 2 x Placebo capsules 12 months	Significantly lower incidence of UTIs in high risk group (p=0.04). No difference in low risk group.
Gallien 2014	R / D-B / P-C	Patients with MS (mean 49 years): 171 (82/89)	2 x Cranberry powder for oral solution 2 x Placebo 1 year	No significant difference between the groups in time to first UTI, no. of UTIs/year and per patient.
Takahashi 2013	R / D-B / P-C	Patients, 20-79 years, with recurrent UTIs: 213 (107/106)	125 mL Cranberry juice (40 mg PACs) 125 mL Placebo beverage 24 weeks	Significantly lower relapse rate of UTIs in the subgroup of females over 50 years (p=0.0425).
Afshar 2012	R / D-B / P-C	Children, 5-18 years, with at least 2 UTIs the year before: 40 (20/20)	2 mL/kg Cranberry juice with or without 37% PACs 1 year	Significantly lower incidence of UTIs (65%; p=0.045) in cranberry group.
Salo 2012	R / D-B / P-C	Children (mean 4 years) with UTIs: 255 (126/129)	5 mL/kg Cranberry juice Placebo 6 months	Less recurrent UTI episodes and significantly less antimicrobial days (p<0.001).
Barbosa-Cesnik 2011	R / D-B / P-C	Women (mean 21.2 years) with acute UTIs: 319 (155/164)	2 × 240 mL Cranberry drink 2 × 240 mL Placebo drink 6 months	No significant difference in recurrence rate of UTIs.
Wing 2008	R / D-B / P-C	Healthy pregnant women at less than 16 weeks gestation:188 (58/63/67)	2 × 240 mL Cranberry drink 2 × 240 mL Placebo drink or 1 of each; until delivery	Reduced frequency of asymptomatic bacteriuria (57%) and all UTIs (41%).
McMurdo 2005	R / D-B / P-C	Older patients, no history of UTI: 376 (187/189)	2 × 150 mL Cranberry juice 2 × 150 mL Placebo drink 15-16 days	Fewer symptomatic UTIs in cranberry group, but not significant (p=0.122).
Stothers 2002	R / D-B / P-C	Women, 21-72 years, with recurrent UTIs: 150 (50/50/50)	3 × 250 mL Cranberry juice 2 Cranberry tablets Placebo; 12 months	Significantly lower Incidence of UTIs in cranberry groups (both p<0.05).
Walker 1997	R / D-B / P-C cross-over	Women, 28-44 years, with recurring UTIs: 10	400 mg Cranberry extract Placebo; 3 months each	Cranberry significantly more effective in reducing occurrence of UTIs (p<0.005).
Avorn 1994	R / D-B / P-C	Elderly women, (mean 78.5 years); 153 (72/81)	300 mL Cranberry cocktail Placebo drink; 6 months	Odds ratio of bacteriuria with pyuria only 42% relative to placebo group (p<0.004).
Temiz 2018	Randomized controlled	Patients after ileal conduit diversion: 20/20/20	Cranberry capsules (2 x 9 mg PACs) Training on avoidance of UTIs No intervention	No differences in temperature, leukocyto-sis, CRP levels; significantly (p<0.05) lower flank pain score with cranberry at weeks 13 to 16; UTIs: 5% in the cranberry group, 40% in control group
Singh 2016	Randomized controlled	Patients, 15-76 years, with recurrent UTIs:72 (36/36)	Cranberry capsules (2 x 60 mg PACs) Lactobacillus capsules (2 x 400 million bacteria) 12 weeks	Significant decrease in recurrent UTI, mean burning micturation score, microscopic pyuria score and bacterial growth in urine (all p< 0.001).
Sengupta 2011	Randomized open controlled	Women, 18-40 years, with recurrent UTIs: 60 (21/23/16)	500 mg Cranberry powder (14.5 mg/g PACs) 1000 mg Cranberry powder (14.5 mg/g PACs) No intervention; 90 days	Significant reduction of E. coli in urine in both cranberry groups (p=0.0151 low dose; p<0.0001 high dose, compared to baseline).

Vidlar 2010	Randomized open controlled	Men (mean 63 years) at risk of prostate disease with UTIs: 42 (21/21)	3 x 500 mg Cranberry powder No intervention 180 days	Significant improvement in IPSS, quality of life, urination parameters compared to baseline (all $p<0.05$). Lower total PSA levels ($p<0.05$) compared to control.
Ferrara 2009	Randomized open controlled	Girls, 3-14 years, with recurring UTIs: 84 (27/28/29)	50 mL Cranberry drink 100 mL Lactobacillus drink No intervention; 6 months	Recurrence of UTIs lower in cranberry group ($p=0.05$).
Kontiokari 2001	Randomized open controlled	Women, (mean 29-32 years) with UTIs caused by E. coli:150 (50/50/50)	50 mL Cranberry drink 100 mL Lactobacillus drink No intervention; 6 months	Recurrence of UTIs lower in cranberry group (6 months, $p=0.023$; 12 months, $p=0.048$).
Haverkorn 1994	Randomized cross-over	Elderly persons (mean 81 years): 17	2 × 15 mL Cranberry juice Same volume of water 4 weeks each	Lower incidence of bacteriuria in cranberry phase than in water-only phase ($p=0.004$).
Barnoiu 2015	Open controlled	Patients undergoing ureteral double J catheter insertion: 62 (31/31)	120 mg Cranberry extract No intervention in routine prophylactic therapy	Significantly lower UTI rates in cranberry group (12.9 vs. 38.7%; $p<0.04$).
Ledda 2017	Open controlled	Adolescents,12-18 years, with recurring UTIs: 36 (19/17)	1 x 120 mg Cranberry extract capsule with 36 mg PACs + life style change Life style change only 2 months	Significantly lower no. of UTIs ($p=0.0001$).
Ledda 2016	Open controlled	Men (mean 67 years) with recurrent UTIs: 44 (23/21)	1 x 120 mg Cranberry extract capsule with 36 mg PACs + life style change Life style change only 2 months	Significantly lower no. of UTIs ($p=0.0062$).
Ledda 2015	Open controlled	Patients (mean 39 years) with recurrent UTIs: 44 (22/22)	1 x 120 mg Cranberry extract capsule with 36 mg PACs + life style change Life style change only 2 months	Significantly lower UTI rates and shorter duration of UTIs in cranberry group.
Kirchhoff 2001	Open controlled	Patients in two hospital geriatric units:338 (187/151)	2 × 175 mL Cranberry juice 2 × 175 mL Mixed (non-cranberry) juice; 4 weeks mean	No significant influence on incidence of UTIs.
Burleigh 2013	Open uncontrolled	Women, 18-64 years, with history of UTIs: 20	42 g sweetened dried cranberries	Significant decrease of mean UTI rate/6 months ($p=0.004$) and of geometric mean of CFU/mL of isolated E. coli ($p=0.040$) pre- and post-consumption.
Sánchez Ballester 2013	Open uncontrolled	Women (mean 35.2 years) with recurrent symptomatic postcoital urinary tract infections: 20	Cranberry extract (118 mg PACs/day) 6 months	Significant reduction of UTIs ($p<0.0001$) and positive urine cultures ($p<0.001$). Significant improvement of quality of life ($p=0.0002$).
Bailey 2007	Open uncontrolled	Women, 25-70 years, ≥ 6 UTIs in past year: 12	2 × 200 mg Cranberry extract 12 weeks	No UTIs in 12 weeks; none in 8 participants after 2 years.
Papas 1966	Open uncontrolled	Adults with acute UTI: 60	450 mL Cranberry juice 21 days	Positive clinical response in 53% of patients; improvement in further 20%.
Pagonas 2012	Retrospective	Kidney transplant recipients (mean 54.5 years): 82 (39/25/18/30)	2 x 50 mL Cranberry juice 3 x 500 mg Methionine Both agents No prophylaxis 1 year before and 1 year after initiation of treatment	Significant reduction in no. of UTIs ($p<0.001$), symptoms ($p<0.008$) and pyuria/nitrituria ($p<0.02$) with cranberry as compared to pretreatment period.

Prevention of bacteriuria and symptomatic UTIs: patients with neurogenic bladder (NB) SCI = Spinal cord injury				
Hess 2008	R / D-B / P-C cross-over	Men, 28-79 years, with NB secondary to SCI: 57	500 mg Cranberry extract Placebo 6 months each treatment	Frequency of UTIs reduced by 70% ($p<0.05$ for both incidence and number of patients with UTIs).
Lee 2007	R / D-B / P-C	Patients, 16-82 years, with NB secondary to SCI: 305 (78/75/75/77)	2 × 800 mg Cranberry 2 × 1 g Methenamine hippurate 800 mg Cranberry + 1 g MH Placebo; Up to occurrence of UTI or 6 months	No significant reduction in incidence of symptomatic UTIs.
Waites 2004	R / D-B / P-C	Adults, 20-73 years, with NB secondary to SCI: 48 (26/22)	2 g conc. Cranberry juice Placebo; 6 months	No reduction in incidence of bacteriuria or UTIs.
Linsen-meyer 2004	R / D-B / P-C cross-over	Adults with NB secondary to SCI: 21	3 × 400 mg Cranberry Placebo; 4 weeks each	No significant effect on bacteriuria or frequency of symptomatic UTI.
Schlager 1999	D-B / P-C cross-over	Paediatric patients, 2-18 years, with NB: 15 (9/6, 6/9)	Cranberry juice concentrate Placebo drink; 3 months each	No significant effect on bacteriuria or frequency of symptomatic UTI.
Foda 1995	Randomized single-blind cross-over	Paediatric patients, 1.4-18 years, with NB: 21	15 mL/kg Cranberry juice 15 mL/kg water 6 months each	No difference in incidence of UTI between cranberry juice and water phases.
Reid 2001	Open controlled cross-over	Patients with NB secondary to SCI: 15	3 × 250 mL Cranberry juice 3 × 250 mL extra water 1 week each	Cranberry juice significantly reduced bacterial biofilm load in the bladder ($p<0.013$).
Mutlu 2012	Open P-C cross-over	Paediatric patients, 4-18 years, with NB: 20	1 x 1 Cranberry capsule 1 x 1 Placebo capsule 6 months each	Significantly lower UTI infection rate ($p<0.012$) and pyuria $p=0.000$).

Metabolic syndrome				
Shidfar 2012	R / D-B / P-C	Men with Type 2 diabetes (mean 54.8 years): 58 (29/29)	240 mL Cranberry juice 240 mL Placebo juice 12 weeks	Significant decreases in serum glucose and apoB ($p>0.05$ and $p>0.01$). Significant increases in serum apoA-1 and PON-1 activity ($p>0.05$ and $p<0.01$) compared to placebo. All parameters ($p<0.01$) compared to baseline.
Basu 2011	R / D-B / P-C	Women with metabolic syndrome: 31 (15/16)	480 mL Cranberry juice 480 mL Placebo juice 8 weeks	Significantly increased plasma antioxidant capacity and decreased oxidized LDL and malondialdehyde (all $p<0.05$).
Schell 2017	Open controlled	Patients with type 2 diabetes: 25 (12/13)	40 g dried cranberries after high-fat breakfast challenge No cranberries	Significantly lower postprandial increases in glucose, lower serum IL-18 and MDA at 4 h, and higher serum total nitrite at 2 h (all $p<0.05$).
Simão 2013	Open controlled	Patients with metabolic syndrome: 56 (20/36)	700 mL energy-reduced cranberry juice Normal diet	Significant increase in adiponectin ($p=0.01$) and folic acid ($p=0.033$) and decrease in homocysteine ($p<0.001$) in relation to baseline and ($p<0.05$) compared to controls.

Cardiovascular risk factors				
Novotny 2015	R / D-B / P-C	Volunteers (mean 50 years): 56 (29/27)	2 x 240 mL low calorie cranberry juice (173 mg phenolics) 2 x 240 mL Placebo beverage (62 mg phenolics/ serving) 8 weeks	Significantly lower fasting serum triglycerides ($p=0.027$), serum C-reactive protein ($p=0.0054$), diastolic blood pressure ($p= 0.048$) and fasting plasma glucose ($p=0.03$).

Flammer 2013	R / D-B / P-C	Patients (mean 49.5 years) with peripheral endothelial dysfunction and cardiovascular risk factors: 84 (32/37)	2 x 230 mL Cranberry juice cocktail 480 mL Placebo juice 4 months	Endothelial progenitor cells expressing osteocalcin significantly (p<0.019) reduced. No differences in metabolic, inflammatory markers or oxidative stress markers and endothelial function
Ruel 2013	R / D-B / P-C cross-over	Obese men (mean 45 years): 35	500 mL/d low calorie cranberry juice cocktail (400 mg total polyphenols, 20.8 mg anthocyanins) 500 mL/d placebo juice 4 weeks each, with 4 weeks wash-out	No significant changes in augmentation index and cardiometabolic profile.
Dohadwala 2011	R / D-B / P-C cross-over	Patients (mean 62 years) with coronary heart disease: 44	480 mL Cranberry juice (835 mg total polyphenols, 94 mg anthocyanins) 480 mL Placebo beverage 4 weeks each treatment	Significant decrease in carotid-femoral pulse wave velocity from 8.3 to 7.8 m/s (p=0.003).
Ruel 2009	S-B	Obese men (mean 51 years): 30	0, 125, 250 and 500 mL low calorie cranberry juice (74 mg PACs/125 mL) 4 weeks, each	Significant decrease in plasma matrix metalloproteinase-9 (p<0.0005) and plasma NOx concentrations(p<0.05).
Ruel 2008	S-B	Obese men (mean 51 years): 30	0, 125, 250 and 500 mL low calorie cranberry juice (74 mg PACs/125 mL) 4 weeks, each	Significant decreases in plasma OxLDL, intercellular adhesion molecule-1 (both p<0.0001), vascular cell adhesion molecule-1 (p<0.05) and systolic blood pressure (p<0.03).
Ruel 2006	S-B	Obese men (mean 51 years): 30	0, 125, 250 and 500 mL low calorie cranberry juice (74 mg PACs/125 mL) 4 weeks, each	Significant decreases in body weight, BMI, oxidative stress (all p<0.05) and waist circumference (p<0.0001) at the end of the study. Significant increases in plasma HDL-cholesterol after 250 mL (p<0.05) and 500 mL (p<0.001).

Prevention of urinary symptoms in patients under radiation therapy				
Hamilton 2015	R / D-B / P-C	Men with prostate cancer + radiation therapy (mean 68 years): 40 (20/20)	Cranberry capsule with 72 mg PAC Placebo capsule During treatment and for 2 weeks after treatment completion	Decreased incidence of cystitis (p=0.058) and pain/ burning (p=0.045).
Campbell 2003	Randomized controlled	Men with prostate cancer + radiation therapy: 112 (55/57)	3 × 118 mL Cranberry juice 3 × 118 mL Apple juice; 9 weeks	No significant difference in urinary symptoms.
Bonetta 2017	Open controlled	Men with prostate cancer + radiation therapy (mean 70 years): 924 (489/435)	200 mg Cranberry extract 6-7 weeks	Less UTIs and recurrent UTIs, radio¬the¬ra-py-induced dysuria and use of antibiotics and NSAIDs significantly reduced.
Bonetta 2012	Open controlled	Men with prostate cancer + radiation therapy: 370 (184/186)	200 mg Cranberry extract 6-7 weeks	Less UTIs and radiotherapy-induced urinary tract symptoms significantly reduced.

Other studies				
Student 2016	R / D-B / P-C	Men with prostate cancer prior to surgery (mean 65 years): 64 (31/31)	3 x 500 mg Cranberry fruit powder capsules 3 x 500 mg placebo capsules 30 days (mean) prior to surgery	Significant decrease of serum PSA 22.5% (p<0.05).

Zhang 2005	R / D-B / P-C	189 adults infected with Helicobacter pylori: (97/92)	2 × 250 mL Cranberry juice 500 mL Placebo juice; 90 days	Significant suppression of H. pylori infection ($p<0.05$) at days 35 and 90.

R = randomised; D-B = double-blind; P-C = placebo controlled; S-B = single-blind.

In an open, controlled study, 150 women (mean age 29-32 years) with UTIs caused by *E. coli* were randomly assigned to one of three treatments: 50 mL of a cranberry-lingonberry drink (containing 7.5 g cranberry juice concentrate and 1.7 g lingonberry juice concentrate) daily for 6 months (n = 50), 100 mL of a *Lactobacillus* drink five days a week for 12 months (n = 50) or no intervention as control (n = 50), with follow-up of all participants at 12 months. The recurrence of UTIs was significantly lower in the cranberry group than in the control group ($p = 0.014$ at 6 months; $p = 0.052$ at 12 months) [Kontiokari 2001].

In an open, cross-over study, 38 elderly persons (mean age 81 years, completed by n=17) were randomized to either 2 × 15 mL of cranberry juice or water daily for 4 weeks, followed by the alternative regimen for a further 4 weeks. There were significantly ($p=0.004$) fewer occurrences of bacteriuria during the cranberry juice phase than in the water-only phase [Haverkorn 1994].

In a randomized, controlled trial, 84 girls (3 to 14 years) with recurrent UTIs received daily for 6 months either 50 mL cranberry juice concentrate (containing 7.5 g cranberry and 1.7 g lingonberry concentrate; n=28) or 100 mL of a *Lactobacillus* drink (4 x 107 cfu; n=27) or no treatment as a control (n=29). During the observation period, 34 episodes of UTIs occurred: 5 in the cranberry group (18.5%), 11 in the *Lactobacillus* group (42.3%) and 18 in the control group (48.1%), showing a significant ($p<0.05$) reduction in the risk of repeated UTIs in the cranberry group as compared to the two other groups [Ferrara 2009].

Men at risk of prostate disease with UTIs, elevated PSA, negative prostate biopsy and clinically confirmed chronic non-bacterial prostatitis received either 1500 mg/d dried powdered cranberries for 6 months (n=21), or no intervention as control (n=21), in a randomized, controlled, open study. After 180 days, patients in the cranberry group experienced a significant improvement in IPSS, quality of life, urination parameters including voiding parameters (e.g. rate of urine flow, average flow, total volume, post-void residual urine volume) as compared to baseline (all $p<0.05$) and lower total PSA levels ($p<0.05$) as compared to control. There was no influence on blood testosterone or serum CRP levels [Vidlar 2010].

A 90-day randomized, controlled trial in 60 women with a history of recurrent UTIs evaluated the efficacy of cranberry powder containing 14.5 mg/g PACs at two doses, 2 x 250 mg/d (n=21) and 2 x 500 mg/d (n=23) compared to an untreated control group (n=16). At the end of the study, the presence of *E. coli* in urine was significantly reduced in both cranberry groups as compared to baseline ($p=0.0151$ for the low dose and $p<0.0001$ for the high dose), whereas it remained unchanged in the untreated controls. Relief of symptoms was also reported after both cranberry doses. No significant changes were observed in haematological and serum biochemical parameters [Sengupta 2011].

In two geriatric units (mean duration of stay 4 weeks), urine samples from patients with suspected urinary tract infections were cultured and significant growth of bacteria led to antibiotic treatment. Over a 12-month study period, participating patients in one unit received 2 × 175 mL of cranberry juice daily (n = 187) for the length of their stay, while those in the other unit received the same amount of a mixed berry juice (n = 151). Cranberry juice treatment did not significantly influence the incidence of urinary tract infections [Kirchhoff 2001].

In a pilot study involving 44 patients with recurrent UTI, the frequency of UTIs for two months before treatment was compared to that during treatment for two months with120 mg cranberry extract daily (containing 36 mg PACs) plus standard life style and hygiene management advice, or standard management advice only (control). The reduction of UTIs as compared to the pre-treatment period was 73.3% in the cranberry group and 15.4% in the lifestyle change only group ($p=0.012$). The duration of UTIs was also significantly shorter with the extract (2.5 vs. 3.6 days; $p<0.05$) [Ledda 2015]. In a similar study using the same preparation and dosage in 43 elderly men, the number of UTIs in the cranberry group was significantly ($p=0.0001$) reduced from 3.2 before treatment to 0.8 during treatment. No significant change was seen following the life style change only, demonstrating a significant ($p=0.0062$) between group difference [Ledda 2016]. An identical trial was performed in 36 adolescents (12-18 years). The mean number of UTIs during the treatment period in the supplemented group (0.31±0.2) was significantly ($p= 0.0001$) lower compared to both control (2.3±1.3) and to before treatment (1.74±1.1) [Ledda 2017].

A prospective, open trial compared UTI rates following standard prophylactic treatment before ureteral double J catheter insertion either with (n=31) or without (n=31) addition of 120 mg cranberry extract (not further specified). UTI percentage was lower in the cranberry group (12.9% compared to 38.7%; $p=0.04$) compared to the standard prophylactic treatment only [Barnoiu 2015].

In an open pilot study, 12 women (25-70 years) with a history of at least 6 UTIs in the preceding year took 2 × 200 mg of a concentrated cranberry extract (30% total phenols, 25% PACs) daily for 12 weeks. Urinalysis was carried out at baseline and at monthly intervals, and all 12 participants were followed up two years later. During the 12-week study none of the women had a UTI and two years later eight of the women who continued to take cranberry were still free from UTIs [Bailey 2007].

In an open study, cranberry juice was administered to 60 patients with diagnoses of acute UTI. After 3 weeks of treatment with 450 mL/d of cranberry juice, 32 patients (53%) had a positive clinical response (no urogenital complaints, less than 100,000 bacteria per mL urine) and moderate improvement was evident in a further 12 patients (20%), while 16 (27%) showed neither bacteriological improvement nor symptomatic relief [Papas 1966].

In an observational, prospective study, women (n=20) with recurrent symptomatic postcoital UTIs received an extract (118 mg/d PACs) for 6 months as follows: after the 1st sexual intercourse in a week 1 dose daily for 3 days, and after the 2nd and following intercourses in a week 1 dose postcoital. The number of UTIs was significantly ($p<0.0001$) reduced from 2.8 in the 3 months prior to treatment to 0.2 at month 6. The mean quality of life assessed on a VAS was 62.4±19.1 at baseline and increased to 78.2±12.4 at month 6 ($p=0.0002$). All patients had an infection with positive urine culture at baseline, while after

6 months there were only 3 symptomatic infections (p<0.001) [Sánchez Ballester 2013].

Women (n=20; 18-64 years, mean age 37) with a history of recurrent UTIs consumed 42 g/day of sweetened dried cranberries for two weeks. The mean UTI rate per six months pre- and post-consumption decreased significantly (p=0.004) from 2.4 to 1.1. A significant decrease (p=0.040) of *E. coli* isolated from rectal swab eluates pre- and post-consumption was observed [Burleigh 2013].

Women with recurrent UTIs (n=24) consumed 120 mL cranberry juice on average 6 days/week for 8 weeks. At weeks 2, 4 and 8, the Interstitial Cystitis Symptom Index (ICSI) and the Interstitial Cystitis Problem Index (ICPI) were used to evaluate UTI symptoms. Both scores decreased significantly from 2 to 8 weeks (ICSI p<0.0001; ICPI p<0.01) [Bass-Ware 2014].

A retrospective analysis of 82 kidney transplant recipients compared the influence of prophylaxis with cranberry juice (2 x 50 mL/d, n=39) or L-methionine (3 x 500 mg/d, n=25) or both (n=18) on annual recurrent UTIs before and after initiation of prophylaxis, as well as in thirty patients without any prophylactic treatment (control). Overall, prophylactic treatment significantly (p<0.001) decreased the annual UTI incidence by 58.3%, with no change in the control group. Cranberry reduced the annual number of UTI episodes by 63.9% (p<0.001), symptoms such as fever, dysuria, urgency (p<0.008) and pyuria/nitrituria (p<0.02) as compared to the period before the start of prophylaxis. In the L-methionine group, UTI episodes were reduced by 48.7% as well as symptoms and pyuria/nitrituria (all p<0.001). The combination led to a reduction of UTI episodes by 64.5% (p<0.001), of symptoms (p<0.03) and of pyuria/nitrituria (p<0.008). In patients without prophylaxis all parameters remained unchanged [Pagonas 2012].

Prevention of UTI:
Patients with neurogenic bladder
In a randomized, double-blind, placebo-controlled study with a cross-over design, 57 men (28-79 years) with spinal cord injuries and neurogenic bladder were randomized to receive twice daily for 6 months either a 500 mg cranberry extract (not further specified) tablet or placebo, followed by the alternative preparation for a further 6 months, with no wash out period. The primary outcome criterion was the incidence of UTIs; 47 patients completed the study. There were 31 episodes of bacteriuria in the cranberry period and 37 in the placebo period. However, during the cranberry period 6 patients had 7 UTIs, compared to 16 patients and 21 UTIs in the placebo period (p<0.05 for both number of patients and incidence). Cranberry reduced the frequency of UTIs to 0.3 per year compared to 1.0 per year on placebo, with a significant p<0.05) reduction in the likelihood of a UTI and symptoms in every month. Patients with a glomerular filtration rate higher than 75 mL/minute had the greatest benefit [Hess 2008].

A much larger randomized, double-blind, placebo-controlled study examined the efficacy of cranberry (no further details) and methenamine hippurate (MH) in the prevention of symptomatic UTIs in patients (aged 16-82 years, predominantly male) with spinal cord injury (SCI) and neuropathic bladder, but stable bladder management. Randomized into groups, the patients received one of four daily treatments: 2 × 800 mg of cranberry (n = 78), 2 × 1 g of MH (n = 75), 800 mg of cranberry + 1 g of MH (n = 75) or placebo (n = 77). The primary outcome measure was the time from commencement of treatment to the occurrence of a symptomatic UTI, or 6 months if none occurred. No significant benefit in the prevention of UTIs was evident from cranberry or MH treatment [Lee 2007].

In a randomized, double-blind, placebo-controlled study, patients with neurogenic bladder secondary to SCI, and baseline urine cultures showing at least 105 colonies of bacteria/mL, received either 2 g of concentrated cranberry juice (n = 26) or placebo (n = 22) daily for 6 months. Urinalysis and cultures were performed initially and at monthly intervals. No significant differences between groups were observed with respect to bacteriuria and pyuria. In the verum group 10 participants (38.5%) had a total of 16 symptomatic UTI episodes during the 6-month period, while in the placebo group 8 participants (36.4) had 14 symptomatic UTI episodes [Waites 2004].

In a randomized, double-blind, placebo-controlled cross-over study, 37 patients with neurogenic bladder secondary to SCI were randomly assigned to treatment with either 3 × 400 mg cranberry tablets or placebo daily for 4 weeks. After a wash-out period of 1 week the participants took the alternative treatment for a further 4 weeks. The participants were checked weekly and urine analyses were carried out; results on 21 patients were available for evaluation. No favourable effect of the cranberry treatment was evident from urinary bacterial and white blood cell counts or the incidence of UTIs [Linsenmeyer 2004].

A pilot study in 15 patients with SCI demonstrated that drinking 3 glasses of cranberry juice/d significantly reduced the bacterial biofilm load in the bladder (p = 0.013 compared to baseline) due to a reduction in adhesion of Gram-negative (p = 0.054) and Gram-positive (p = 0.022) bacteria to bladder epithelial cells. Intake of the same amount of water did not significantly reduce bacterial adhesion or biofilm presence [Reid 2001].

In a double-blind, placebo-controlled, cross-over study the effect of cranberry juice on the prophylaxis of bacteriuria was determined in children with neurogenic bladder receiving intermittent catheterization. A cranberry juice concentrate (corresponding to 300 mL of cranberry juice) or a placebo drink was given to 15 children daily for 3 months, followed by the alternate treatment for a further 3 months. In this population cranberry juice had no effect on the frequency of bacteriuria [Schlager 1999].

In a randomized, single-blind cross-over study, 40 paediatric patients (1.4-18 years) with neurogenic bladder managed by clean intermittent catheterization were randomized to daily treatment with either a cranberry cocktail (30% cranberry concentrate) or water at 15 mL/kg b.w., divided into 3-4 doses, for 6 months then the alternative treatment for a further 6 months; 21 patients completed the study, of whom 11 received cranberry first. No beneficial effect of cranberry consumption greater than that of water was evident in this study. Fewer UTIs were observed in 9 patients taking cranberry juice and in 9 given water; no difference was noted in 3 patients [Foda 1995].

Children with neurogenic bladder (n=20; mean age 7.25 years) received placebo for 6 months and after a one week break, cranberry extract (not further specified) for a further 6 months in a prospective study. UTI rate and pyuria were significantly (p<0.012 and p=0.000) reduced as compared to placebo [Mutlu 2012].

Urinary symptoms during radiation therapy
During 7 weeks of treatment for prostate cancer by external radiation therapy, 112 men were randomized to daily consumption of either 3 × 118 mL of cranberry juice (n = 55) or the same volume of apple juice (n = 57). No significant difference was observed between the two groups regarding the urinary symptoms in International Prostate Symptom Scores [Campbell 2003].

In a randomized, double-blind, placebo-controlled study, 40 men with prostate cancer undergoing radiation therapy took either cranberry extract (72 mg PACs/day) or placebo throughout their course of radiotherapy and for 2 weeks after treatment completion. The incidence of cystitis was lower (p=0.058) in those taking cranberry (65%) than placebo (90%). While the incidence of pain/burning was significantly (p=0.045) decreased compared to placebo [Hamilton 2015].

Of 370 patients receiving radiotherapy for prostate cancer, 184 were treated with 200 mg of an extract standardized to 30% PACs daily for 6-7 weeks in a non-randomized, open study. In the untreated control group (n=186), 45 UTIs (24.2%) were observed, compared to 16 UTIs (8.7%) in the cranberry group. Urinary symptoms due to radiotherapy were significantly milder in the cranberry group: nycturia (31% vs. 54% increase, p<0.001), urgency (31% vs. 54% increase, p<0.0001), micturition frequency (p<0.0006) and dysuria (p<0.0001) [Bonetta and Di Pierro 2012].

In a similar, randomized, open study with the same medication, 924 patients were enrolled, with 489 receiving the extract and 435 in an untreated control group. Significantly (p=0.0001) less patients experienced UTIs in the cranberry group (53 patients; 10.8%) compared to the control group (107 patients; 24.6%). Recurrent UTIs were seen in 10 control patients (2.3%) and only 4 cranberry patients (0.8%) (p=0.004). Use of antibiotics and NSAIDs was significantly (p<0.001) less with the extract, and a significant (p<0.04-0.001) reduction of dysuria (degrees 0 to 3) was observed as compared to control [Bonetta 2017].

Metabolic syndrome
In a randomized, double-blind, placebo-controlled study, type 2 diabetics on oral glucose-lowering medication (n=30) received 3 x 500 mg cranberry extract or placebo for 12 weeks to examine changes in lipid profiles, oxidized LDL, glycaemic control, components of the metabolic syndrome such as abdominal obesity and raised blood pressure, C-reactive protein and urinary albumin excretion. LDL cholesterol decreased significantly in the cranberry group (p<0.005 compared to baseline and p<0.001 compared to placebo) as well as total cholesterol and the ratio total:HDL cholesterol (p=0.020 and 0.044 respectively, compared to baseline; p<0.001 and p=0.032 respectively, compared to placebo). All other parameters did not change significantly [Lee 2008].

In a randomized, double-blind, placebo-controlled trial, women with metabolic syndrome consumed 480 mL/d cranberry juice (238 mg PACs) or placebo for 8 weeks (n = 15-16/group). The juice increased plasma antioxidant capacity (1.5 ± 0.6 to 2.2 ± 0.4 µmol/L) and decreased oxidized LDL and malondialdehyde (120.4 ± 31.0 to 80.4 ± 34.6 U/L and 3.4 ± 1.1 to 1.7 ± 0.7 µmol/L, respectively), at 8 weeks (all significant (p<0.05) compared to placebo). The intake of juice did not improve blood pressure, glucose and lipid profiles, C-reactive protein and IL- 6 [Basu 2011].

Type 2 diabetic male patients (n=58) were randomized to 240 mL cranberry juice or a placebo drink daily for 12 weeks in a randomized, double-blind trial. With the juice, significant decreases in serum glucose and apoB (p<0.05 and p<0.01, respectively) and significant increases in serum apoA-1 and PON-1 activity (p>0.05 and p<0.01, respectively) were observed at the end of study as compared to placebo as well as compared to baseline (p<0.01 for all) [Shidfar 2012].

Patients (n=56; 42-56 years; BMI 26.3-38.4) with metabolic syndrome consumed a low-calorie cranberry juice (0.7 L/d; 364 mg total phenolics) or placebo for 60 days. The verum group showed a significant increase in adiponectin (p=0.010) and folic acid (p=0.033) and a decrease in homocysteine (p<0.001) in relation to baseline and in comparison with controls (p<0.05). No significant changes in the pro-inflammatory cytokines TNF-α, IL-1 and IL-6 or in C-reactive protein were observed. Oxidative stress measurements resulted in significantly (p<0.05) decreased lipid peroxidation and protein oxidation levels as compared to control [Simao 2013].

Postprandial effects were studied in obese patients with type 2 diabetes (n=25) in a randomized, cross-over trial at fasting and 1, 2 and 4 hours after a high-fat breakfast with or without dried cranberries (40 g). Postprandial serum glucose levels were significantly (p<0.05) lower after cranberries vs. control at 2 and 4 hours. No significant differences between the groups were observed in insulin, insulin resistance, lipid profiles and blood pressure. Among biomarkers of inflammation and oxidation, postprandial serum IL-18 and MDA were significantly lower at 4 h, and serum total nitrite was higher at 2 h in the cranberry group (all p < 0.05). No effects were noted on CRP or IL-6 [Schell 2017].

Cardiovascular risk factors
In a single-blind study, 30 obese men received a low calorie cranberry juice cocktail (CJC) containing 125, 250 and 500 mL cranberry juice (adjusted to 500 mL with placebo cocktail, 74 mg PACs/125 mL). Placebo cocktail (500 ml/d) was consumed during a 4 week run-in period, followed by three 4-week periods with the increasing doses of CJC. Small but significant decreases were observed for body weight, BMI (both p<0.05) and waist circumference (p<0.0001) at the end of the study, as well as significant increases in plasma HDL-cholesterol after 250 mL (p<0.05) and 500 mL (p<0.001). Changes in plasma apo A-I concentration and the reduction in plasma TG were not significant. Plasma total and LDL-cholesterol and circulating apoB levels remained unchanged. Plasma total antioxidant capacity changed significantly: after an increase with 125 mL/d, it decreased with 250 mL and 500 mL (both p<0.05 vs. 125 mL CJC/d). Oxidative stress, as shown by the plasma nitrite/nitrate concentration, was reduced significantly at the end of the intervention (p<0.05 vs. 0 mL CJC/d) [Ruel 2007].

At the end of the study significant decreases in plasma OxLDL cholesterol concentrations, plasma intercellular adhesion molecule-1 (both p<0.0001), vascular cell adhesion molecule-1 (p<0.05) and systolic blood pressure (p<0.03) were observed in the same patients and set-up [Ruel 2008]. The treatment also resulted in a significant decrease in plasma matrix metalloproteinase-9 (p<0.0005) and plasma NOx concentrations (p<0.05) after 12 weeks vs. run-in [Ruel 2009].

In a randomized, placebo-controlled, cross-over study, 44 patients with coronary heart disease received 4 weeks each of 480 mL/d cranberry juice (54% juice, 835 mg total polyphenols, 94 mg anthocyanins) and placebo, with a 2 week wash-out period. Vascular function was measured before and after each beverage. Mean carotid-femoral pulse wave velocity, a measure of central aortic stiffness, decreased after cranberry juice (from 8.3 to 7.8 m/s) in contrast to an increase (8.0 to 8.4 m/s) after placebo (p= 0.003). Brachial artery flow-mediated dilation, digital pulse amplitude tonometry, blood pressure and carotid-radial pulse wave velocity as well as the biochemical profile including TC, LDL-C, HDL-C, triglycerides, glucose, insulin and CRP, did not change significantly [Dohadwala 2011].

The augmentation index (AIx), an index of arterial stiffness, and the cardiometabolic profile of 35 overweight men did not show any significant changes in a randomized, placebo-controlled, double-blind, cross-over study after consumption of 500 mL low

calorie cranberry juice cocktail (400 mg total polyphenols, 20.8 mg anthocyanins) or 500 mL placebo juice/d for 4 weeks. After a 4-week wash-out period the groups were crossed for another 4 weeks. However, a significant (p=0.019) decrease in AIx was noted after cranberry cocktail as compared to baseline [Ruel 2013].

In a randomized, double-blind, placebo-controlled trial, 84 patients with peripheral endothelial dysfunction and cardiovascular risk factors received either 2 x 230 mL/d of a cranberry juice cocktail (1740 µg/mL total phenols, 151 µg/mL total anthocyanins, 2662 µg/mL total PACs) or placebo. The 4-month protocol was completed by 69 patients (cranberry n=32; placebo n=37). No differences between the groups were seen in metabolic, inflammatory or oxidative stress markers and endothelial function. Only endothelial progenitor cells expressing osteocalcin were significantly (p<0.019) reduced by the juice [Flammer 2013].

A double-blind, placebo-controlled, parallel-arm study was conducted in 30 women and 26 men who consumed 240 mL of a low calorie cranberry juice (LCCJ; 173 mg phenolics/serving) or a matched placebo (62 mg phenolics/serving) twice daily for 8 weeks. Fasting serum triglycerides (TGs) were significantly (p=0.027) lower after LCCJ as compared to placebo. Individuals with higher TGs at baseline experienced a better effect. Serum TC, LDL and HDL cholesterol as well as serum apo A-I, apo A-II, and apoB did not differ between the groups. Serum C-reactive protein significantly (p=0.0054) decreased with LCCJ, which also lowered diastolic blood pressure (p= 0.048) and fasting plasma glucose (p=0.03) compared with placebo. The effect on homeostasis model assessment of insulin resistance was more beneficial for participants with high baseline values (p=0.035) [Novotny 2015].

Other effects

In a randomized, double-blind, placebo-controlled study, 189 patients (aged 48.9 ± 11.2 years) with *Helicobacter pylori* infections were randomized to 2 × 250 mL of cranberry juice (n = 97) or matching placebo beverage (n = 92) daily for 90 days. The degree of *H. pylori* infection was determined by a ^{13}C-urea breath test before randomization and on days 35 and 90 of intervention. At day 35, ^{13}C urea breath tests were negative for 14 out of 97 patients in the cranberry group and 5 out of 92 in the placebo group. At day 90 results were negative for 14 out of 97 patients in the cranberry group (of whom 11 had also been negative at day 35) and for 5 out of 92 in the placebo group (of whom 2 had also been negative at day 35). The results were significantly (p<0.05) in favour of cranberry treatment [Zhang 2005].

In a randomized, double-blind placebo-controlled study, 64 patients with prostate cancer received, for a mean of 30 days prior to surgery, either 1500 mg cranberry fruit powder (n=31) or placebo (n=31). Serum PSA significantly (p<0.05) decreased by 22.5% in the cranberry group as compared to baseline, but increased by 0.9% with placebo. A trend to downregulation of urinary beta-microseminoprotein and serum γ-glutamyltranspeptidase, as well as upregulation of IGF-1 was found after cranberry treatment. There were no changes in prostate tissue markers [Student 2016].

Clinical reviews and meta-analysis

From a review of 10 randomized controlled studies [Avorn 1994, Haverkorn 1994, Foda 1995, Walker 1997, Schlager 1999, Kontiokari 2001, Stothers 2002, Waites 2004, Linsenmeyer 2004, McMurdo 2005] involving a total of 1049 participants, it was concluded that cranberry juice may decrease the number of symptomatic UTIs over a 12-month period. Cranberry products were more effective in reducing the incidence of UTIs in women with recurrent UTIs than in elderly men and women or in patients requiring catheterisation [Jepson 2008].

A meta-analysis of pooled results from four studies [Stothers 2002, Kontiokari 2001, Waites 2004, McMurdo 2005] led to the conclusion that cranberry products significantly reduced the incidence of UTIs for up to 12 months in comparison with placebo or control [Jepson 2008].

An updated review and meta-analysis of 24 studies (six cross-over studies, 11 parallel group studies with two arms; five with three arms, and two studies with a factorial design) comprised a total of 4473 participants taking various cranberry products. Compared with placebo, water or no treatment, cranberry products did not significantly reduce the occurrence of symptomatic UTI overall or for any of the subgroups. The effectiveness of cranberry was also not significantly different to antibiotics for women and children. There was no significant difference between gastrointestinal adverse effects from cranberry products compared to placebo/no treatment [Jepson 2012].

Other reviewers also concluded that clinical studies have documented the efficacy of cranberry juice in women with recurrent UTI, with the strongest evidence for sexually active women. However, many of the available studies suffer from limitations, including high numbers of drop-outs and lack of intent-to-treat analysis. The limitation of these studies is the lack of uniformity with regard to the intervention, including the type of cranberry product evaluated (juice, sweetened cocktail, dried juice or extracts in capsules and tablets), the concentration or content of the product, the dosing regimen and duration of intervention [Raz 2004, Nowack 2008, Micali 2014].

Thirteen randomised, controlled trials on the use of cranberry products in the prevention of UTIs, including 1616 subjects, were evaluated qualitatively and 10 of these trials, including a total of 1494 subjects, were further analysed in quantitative synthesis in a systematic review and meta-analysis. The results indicated that cranberry products are associated with a protective effect against UTIs. In subgroup analysis, cranberry products seemed more effective in women with recurrent UTIs, female populations, children, cranberry juice drinkers and subjects using cranberry-containing products more than twice daily [Wang 2012a].

A review of eight clinical trials examined the use of cranberry products for the prevention of UTIs in children and adolescents (aged between 1 month and 18 years). Three studies had been performed in otherwise healthy children and five in paediatric patients with underlying urogenital abnormalities, of which two small trials compared cranberry to antibiotics. In otherwise healthy children, cranberry use was associated with a reduction in the overall number of UTIs and a decrease in the number of antibiotic days per year for UTI treatment. In patients with urogenital abnormalities, results were contradictory. However, cranberry products had similar efficacy as cefaclor or trimethoprim [Durham 2015].

In a meta-analysis of 7 randomized controlled trials in generally healthy, non-pregnant women (n=1498 participants; >18 years) with a history of UTI, comparison of cranberry intervention to placebo or control showed a reduced risk of UTI by 26% with cranberry [Fu 2017].

A compilation of 25 studies involving 4947 participants, in a systematic review with meta-analysis, concluded that intake of cranberry products reduced the incidence of UTIs: patients at some risk for urinary tract infections were more susceptible to the effects of cranberry [Luis 2017].

Four studies in individuals with spinal cord injuries were evaluated in a review which concluded that cranberry supplementation is ineffective for prevention of UTIs in these patients [Navarrete-Opazo 2017].

Pharmacokinetic properties

Pharmacokinetics in vitro
The transport of A-type procyanidin dimers, trimers and tetramers in two fractions from spray-dried cranberry powder through differentiated human intestinal epithelial Caco-2 cell monolayers was studied. After 2 hours, a transport rate of 0.6% for a dimer in one fraction and of 0.4% for trimers and 0.2% for tetramers from another fraction to the basolateral side was observed [Ou 2012].

After incubation of a PAC-enriched extract with human gut microbiota, benzoic acid, 2-phenylacetic acid, 3-phenylpropionic acid, 2-(3-hydroxyphenyl)acetic acid, 2-(4-hydroxyphenyl)acetic acid, 3-(3-hydroxyphenyl)propionic acid and 2-(3,4-dihydroxy-phenyl)acetic acid were identified as metabolites. The mass recovery of the metabolites after 24 hours was equivalent to 20% of the applied procyanidins [Ou 2014].

Incubation of a cranberry extract (9.76 mg/g benzoic acids, 11.1 mg/g hydroxy-cinnamic acids, 2.1 mg/g flavan-3-ols, 0.055 mg/g anthocyanins) with human colonic bacteria resulted in the determination of 27 compounds (phenylacetic, phenylpropionic, benzoic and cinnamic acids, phenols and metabolites of flavan-3-ols, such as phenyl-γ-valerolactones and phenylvaleric acid derivatives). Benzoic acid, 4-hydroxy-5-(3´-hydroxyphenyl)-valeric acid and phenylacetic acid were the most abundant compounds [Sanchez-Patan 2015].

Pharmacokinetics in animals
Sprague-Dawley rats were fed a diet containing 0, 3.3, 6.6 or 33 g/kg of concentrated cranberry powder (1.51 mg/g total anthocyanins, 56.2 mg/g procyanidins, 94.2 mg/g total phenolics, 214 mg/g glucose and 70.6 mg/g fructose) for 50 days. Urine was collected over 24 hours between days 30 and 35 and nineteen phenolic acids were determined. Hippuric, 4-hydroxycinnamic, 3-hydroxyphenylacetic, 4-hydroxyphenylacetic and 3-hydroxyphenylpropionic acid were the major metabolites. For several phenolic acids, the percentage excreted in the conjugated form was generally consistent for the various levels of cranberry in the diet and ranged from 65 to 100% for the individual acids [Prior 2010].

Cranberry concentrate powder (1 g/kg b.w.; 5 days a week for 10 months) was administered orally to Fischer-344 rats. Quercetin, isorhamnetin, myricetin, kaempferol, proanthocyanidin A2, peonidin 3-O- and cyanidin 3-O-galactoside as well as 13 conjugated metabolites of quercetin and isorhamnetin were identified in the urine after treatment. Very low levels of isorhamnetin (0.48 ng/mL) and proanthocyanidin A2 (0.541 ng/mL) were determined in plasma samples. Analysis of amethanolic extraction of urinary bladder tissue showed that the chronic administration of the concentrate resulted in accumulation of quercetin and isorhamnetin in the bladder [Rajbhandari 2011].

Addition of 5% freeze-dried cranberry powder to a fructose-rich diet for Sprague-Dawley rats resulted in significant ($p<0.05$) changes of urinary excretion of 10 phenolic acids after 30 to 40 days: total hippuric acid as the main metabolite increased by >6000 µg/day relative to control, 4-hydroxycinnamic acid and 3-methoxy-4-hydroxyphenylacetic acid each by >180 µg/day [Khanal 2014].

An extract enriched in PACs was administered orally to Sprague-Dawley rats (250 mg/kg b.w. twice daily, at 0 and 12 hours) and urine collected for 24 hours. The urinary metabolome at baseline and after ingestion of the extract showed a clear difference. The urinary levels of hippurate, succinate, lactate and two unknown metabolites increased and metabolites such as α-ketoglutarate and citrate decreased [Liu 2016].

In a metabolomic study, the effects of cranberry supplementation (100 mg/kg/d containing 11 mg/kg PAC-A and 4 mg/kg PAC-B; orally for 35 days) were studied in Sprague-Dawley rats. Microbial PAC metabolites, such as valeric acid and valerolactone derivatives, were shown to be related to cranberry consumption. An increased urinary excretion of glucuronidated metabolites was also observed. The biomarkers of polyphenol intake, catechol sulphate, benzoyl glucuronide and hippuric acid were increased in urine [Peron 2017a].

Pharmacokinetics in humans
Blood samples from a fasted healthy volunteer before, and at 45 and 270 minutes after, ingestion of a very large single dose (1800 mL) of cranberry juice were analysed. No benzoic, phenolic or flavonoid compounds were observed in the plasma before cranberry consumption. Benzoic acid (3 µg/mL) and several hydroxybenzoic acids were detected after 45 and 270 minutes, as well as two hydroxycinnamic acids after 270 minutes, but no free flavonoids [Zhang 2004].

Consumption of cranberry juice (3 x 250 mL/d for 2 weeks; 7 mg/L salicylate) or placebo by healthy women (n=11/group) was associated with a significant increase ($p<0.001$) of salicyluric and salicylic acids in urine at weeks 1 and 2 in the cranberry group compared to placebo. After 2 weeks, a small but significant ($p<0.05$) increase in salicylic acid in plasma was observed as compared to placebo [Duthie 2005].

The excretion of anthocyanins in human urine was investigated in 11 healthy volunteers after consumption of 200 mL of cranberry juice (650 µg total anthocyanins). Maximum urinary levels of anthocyanins were reached between 3 and 6 hours after ingestion. After 24 hours, about 5% of the total anthocyanins had been recovered in the urine, the most abundant compound being peonidin 3-O-galactoside [Ohnishi 2006].

A study in 15 volunteers (mean age: 62 years) with coronary artery disease revealed marked inter-individual differences in plasma anthocyanin pharmacokinetics after consumption of 480 mL cranberry juice (54% juice; 835 mg total polyphenols; 94.5 mg anthocyanins). Maximum anthocyanin concentrations were detected between 1 and 3 h. Anthocyanins showed notable individual differences in C_{max} and AUC_{0-4h}. The pattern of anthocyanin glucosides in plasma and urine reflected their relative concentration in the juice. Plasma concentrations of the individual anthocyanins ranged between 0.56 and 4.64 nmol/L. Total recovery of urinary anthocyanins was 0.79% of the ingested dose [Milbury 2010].

In another study, 11 healthy subjects received 240 mL of a juice, 55 g of a sauce or 40 g dried cranberries, corresponding to doses of 9.1 mg/mL, 11.1 mg/g and 12.4 mg/g phenolics respectively. Blood samples were collected at 0, 0.5, 1, 2, 3 and 4 hours, urine samples before and 6 hours after consumption. Sixteen phenolic, benzoic and cinnamic acids were identified with bound compounds exceeding free phenolics. Plasma levels of most individual compounds declined after reaching a maximum at 0.5 or 1 hours, but for benzoic, trans-cinnamic, vanillic, p-coumaric acids and catechin a second peak was observed. The maximum plasma concentrations of total phenolics were between 0.20 and 1.80 µg/mL, 0.10 and 0.30 µg/mL, and 0.15 and 0.30 µg/mL after consumption of juice, dried fruits and

sauce, respectively. Urinary excretion of phenolic compounds was much higher than in plasma [Wang 2012b].

After overnight fasting, 4 healthy volunteers consumed 0.6 mL/kg of a syrup (1.10% total phenolics, 0.71% PACs, 0.10% anthocyanins). Urine samples were collected before and at 2, 4 and 6 hours after ingestion. More than 30 free polyphenols, phase I and phase II metabolites were tentatively identified such as canthoside A, caffeoyl glucose, dihydroferulic acid, dihydroxybenzoic acid [Iswaldi 2013].

A single-dose pharmacokinetic trial in 10 healthy adults aged over 50 years evaluated the 24 hours absorption and excretion of flavonoids, phenolic acids and PACs from 237 mL of a cranberry juice cocktail (54% juice). Thirteen phenolic acids, 2 flavanols, 4 flavonols, 6 anthocyanins, 4 anthocyanin glucuronides, and 1 PAC were identified. A bimodal distribution of plasma C_{max} was observed for the flavanols, flavonols and 7 phenolic acids, and a trimodal distribution for caffeic acid. The total concentration of phenolics in plasma reached a peak of 34.2 µg/mL between 8 and 10 h, while in urine this peak was 269.8 µg/mg creatinine appearing 2–4 h earlier [McKay 2015].

The clearance of flavonoids was examined in urine samples of 10 healthy women collected at 0, 90, 225, and 360 min after ingestion of 240 mL cranberry juice containing flavonol glycosides. Five flavonol glycosides were identified, with quercetin-3-galactoside the most abundant cranberry flavonol, exhibiting the highest peak urine concentration (C_{max}) of 1315 pg/mg creatinine. Relative to the other flavonoids with T_{max} of 90–151 min, quercetin-3-arabinoside showed delayed clearance with T_{max} of 237 min [Wang 2016].

Ten healthy volunteers on a low polyphenol and anthocyanin-free diet received a single dose of 450 mL of cranberry juice (787 mg total (poly)phenols). Blood samples were collected before and at 1, 2, 4, 6, 8 and 24 hours, and urine for the 24 h after consumption. Sixty phenolic metabolites were identified such as sulphates of pyrogallol, valerolactone, benzoic acids, phenylacetic acids, glucuronides of flavonols, as well as sulfates and glucuronides of cinnamic acids. The most abundant plasma metabolites were hippuric acids, catechols, benzoic acids and phenylacetic acids. Benzoic acids, cinnamic acids and flavonol metabolites appeared in plasma at 1 - 2 hours post-consumption. The 24 h urinary recovery of phenols was 6.2% with mainly hippuric, phenylacetic and benzoic acids [Feliciano 2016].

Sixty (poly)phenol metabolites were detected in the plasma of ten healthy volunteers after consumption of cranberry juices containing 409, 787, 1238, 1534 and 1910 mg of total cranberry (poly)phenols (TCP). Most of them were conjugated and non-conjugated phenolic acids including ferulic and caffeic acid sulphates. Three flavonoid derivatives, namely kaempferol, kaempferol-3-O-β-D-glucuronide and quercetin-3-O-β-D-glucuronide) were also detected [Rodriguez-Mateos 2016].

In a similar study, the volunteers received juice containing 409, 787, 1238, 1534 and 1910 mg total (poly)phenols. Fourteen out of 60 metabolites and total plasma metabolites exhibited a linear dose response ($p<0.05$). Inter-individual variability of the plasma metabolite concentration was broad and dependent on the metabolite. The mean recovery from urine varied between 10.1% for the lowest and 2.1% for the highest dose. Recovery after the lowest dose was significantly ($p<0.001$) different from all other doses [Feliciano 2017].

Preclinical safety data

Acute toxicity
An acute oral LD_{50} of >5 g/kg b.w. was determined in female Sprague-Dawley rats for a whole cranberry powder standardized to 1.5% PACs according to OECD guidelines [Sengupta 2011].

A single dose of an acidic ethanolic extract (yield 12.5%) did not result in any mortalities in male CD-1 mice at concentrations up to 5.6 g/kg b.w. [Madrigal-Santillan 2012].

Subchronic toxicity
Three cranberry products (90% cranberry fruit solids and 1.4% PACs; 90% cranberry fruit solids and 4.75% PACs; 100% cranberry solids and 1.5% PACs) were added to the feed (1.5 g/kg stock feed) of male Wistar rats for 14 weeks. Controls received stock feed only. No significant effects on oxidative stress parameters, catalase, glutathione peroxidase, glutathione reductase, glutathione transferase, SOD, total antioxidant capacity, TBARs, advanced oxidation protein products, total SH-groups or other clinical chemistry markers were observed as compared to control. Haematological parameters, body weight and food consumption were also unaffected by cranberry intake. Only liver glutathione reductase activity and GSH levels were significantly ($p<0.05$) lower in one of the treated groups and plasma alkaline phosphatase in one of the other cranberry groups as compared to placebo. No changes in gross pathology, organ weights, histopathology or genotoxicity were observed. Total cytochrome P450 levels in the livers were unaffected in all groups [Palikova 2010].

Genotoxicity
Addition of three different cranberry products to the feed of male Wistar rats for 14 weeks did not result in any genotoxic effects [Palikova 2010].

Pregnancy
Pregnant and lactating balb/c mice received 44 mg/kg/d of a preparation (220 mg extract corresponding to 5.5 g cranberries) from copulatory plug until 28 days after delivery. Six weeks after delivery, in spleens of progeny from the cranberry group no differences in macroscopy or spleen weight, but lower numbers and larger diameter of lymphatic nodules (both $p<0.0001$) and more CD19+ and CD8+ lymphocytes ($p<0.05$) were observed as compared to control. No macroscopic abnormalities were observed in the thymus and liver or weights of these organs, but an increase in the diameter of glomeruli was seen in the kidneys ($p<0.05$). Serum levels of creatinine and urea remained unchanged, while only concentrations of VEGF and bFGF in offspring were increased after cranberry compared to control [Balan 2017].

Clinical safety data
Cranberry has a good record of safety at normal therapeutic dose levels [Raz 2004, Lynch 2004].
No adverse reactions were reported in numerous studies [Ferrara 2009, Vidlar 2010, Sánchez Ballester 2013, Ledda 2015, Ledda 2016, Wan 2016, Singh 2016].

In two randomized, placebo-controlled studies involving a total of 526 patients, of whom 187 took cranberry preparations for 15 days [McMurdo 2005] and 100 for 12 months [Stothers 2002], the incidence of adverse events was not greater in verum groups than in placebo groups. In a 6-month comparative study

involving 137 women, of whom 69 took a cranberry extract and 68 took trimethoprim, there were fewer withdrawals and fewer gastro-intestinal upsets in the cranberry group (9% and 19% respectively) than in the trimethoprim group (16% and 25%) [McMurdo 2009].

A trial comparing 480 mg trimethoprim-sulfamethoxazole with 2 x 500 mg cranberry extract daily did not show any significant differences between the groups (n=110/111) in adverse events, which included rash, nausea, vomiting, diarrhoea, constipation and vaginal complaints [Beerepoot 2011].

Patients (n=184) being treated with radiotherapy for for prostate cancer, taking 200 mg of an extract standardized to 30% PACs, did not report any adverse effects or allergic reactions, apart from gastric pain in two cases [Bonetta and Di Pierro 2012]. In a similar study, 4 patients (with chronic gastritis) out of 489 complained of gastric pain [Bonetta 2017].

In a randomized, double-blind study in 171 patients with multiple sclerosis, receiving cranberry powder or placebo, no serious adverse events and no differences between the groups were observed. Gastrointestinal disorders were seen in 17.1% of the verum group and 20.5% of the placebo group [Gallien 2014].

In a controlled, double-blind trial in 85 children from 1 month to 1 year of age, and 107 from 1 to 13 years of age, a syrup containing 3% cranberry extract was well tolerated with no adverse effects reported [Fernández-Puentes 2015].

No differences in adverse effects between 2 x 2 cranberry capsules daily for 6 weeks and placebo were observed in a randomized, double-blind, placebo-controlled trial in 160 women after gynaecological surgery. Gastrointestinal upset was the most commonly reported event in both groups [Foxman 2015].

In a trial including 185 elderly patients taking 2 cranberry capsules/day (equivalent to appr. 600 mL cranberry juice) or placebo for 1 year, the 14 protocol-related, non-serious adverse events (e.g. altered mental status, gastrointestinal or oral cavity disturbance, skin and soft tissue event, weight loss) were of similar frequency in both groups [Juthani-Mehta 2016].

In a randomized, double-blind, placebo-controlled trial in 373 women consuming 240 mL cranberry beverage/d or placebo, adverse events including headache, sinusitis and upper respiratory infection occurred in ≤5% in both groups and were not significantly different [Maki 2016].

Pregnancy
In a study involving pregnant women taking cranberry juice or placebo from less than 16 weeks of gestation to delivery, 73 women out of 188 (38.8%) withdrew, 44 due to gastrointestinal upsets [Wing 2008].

In a placebo-controlled study, 72 pregnant women consumed at least 1 × 240 mL of a cranberry juice cocktail (CJC) daily from about 16 weeks of gestation to delivery; 18 women took 2 × 240 mL and 8 took 3 × 240 mL of the CJC. There were no differences between cranberry and placebo groups with regard to obstetric or neonatal outcomes [Wing 2008].

Indirect evidence from a systematic review (including a survey of post-partum women who had taken cranberry preparations during pregnancy) suggested minimal risk during pregnancy when cranberry is consumed in food amounts [Dugoua 2008].

In the Norwegian Mother and Child Cohort Study including more than 100,000 pregnancies from 1999 to 2008, 919 women reported cranberry use during pregnancy (n=121 in the first trimester, n=566 in early pregnancy). No increased risk of congenital malformations, stillbirth/neonatal death, low birth weight, small for gestational age, preterm birth, low Apgar score (<7), neonatal infections or maternal vaginal bleeding in early pregnancy were seen. The only association was between cranberry use in late pregnancy and vaginal bleeding after pregnancy week 17, further sub-analyses of more severe bleeding outcomes did not show a significant risk [Heitmann 2013].

In a study on the compliance with, and tolerability of, cranberry ingestion for prevention of asymptomatic bacteriuria in pregnancy, 33 women participating until delivery received 2 cranberry capsules (containing 32-34 mg PACs; n=14) or placebo capsules (n=19). No antepartum complications, such as foetal malformation, intrauterine foetal growth restriction, oligohydramnios or polyhydramnios were observed. Neonatal outcomes were similar between the two groups [Wing 2015].

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

VERBASCI FLOS

Mullein flower

2014

DEFINITION

Mullein flower consists of the dried flower, reduced to the corolla and the androecium of *Verbascum thapsus* L., *V. densiflorum* [syn. *V. thapsiforme* Schrad] and *V. phlomoides* L.

The material complies with the monograph of the European Pharmacopoeia [Mullein flower].

CONSTITUENTS

The characteristic constituents include flavonoids (1.5-4%) such as apigenin, luteolin and quercetin together with their glycosides, tamarixetin glycosides, diosmin, hesperidin, chrysoeriol, eriodictyiol, kaempferol and rutin in *V. phlomoides* (total content 2.4%) [Pápay 1980; Tschesche 1979; Klimek 2010] and in *V. densiflorum* (total content 0.61-0.68%), whereas the flowers of *V. thapsus ssp. thapsus* contain 6-hydroxyluteolin-7-O-glucoside, 3'-methylquercetin and 7,4'-dihydroxyflavone-4'-rhamnoside and a further luteolin triglycoside (verbacoside) [Klimek 2010; Mehrotra 1989; Souleles 1989; Hein 1959].

Iridoid glycosides (0.56% in *V. phlomoides*, 0.13% in *V. densiflorum*) [Grzybek 1996] such as aucubin and catalpol, together with their xylosides and p-coumaroyl esters [Klimek 1996; Osváth 1982; Swiatek 1982].

Phenylethanoid glycosides as verbascoside (acteoside) and forsythoside B (0.74-0.78% in *V. densiflorum*, less than 0.17% in *V. phlomoides*) [Klimek 2010; Grzybek 1996].

Phenolic acids such as caffeic, p-coumaric, ferulic or p-hydroxybenzoic acid and their glycosides [Blohme 2007; Klimek 1996; Osváth 1982]

Triterpene saponins (0.007% isolated from flowers and 0.028% from petals of *V. phlomoides*) as verbascosaponin, the closely related verbascosaponins A and B and desrhamnosylverbascosaponin [Klimek 1996; Schröder 1993a,b; Tschesche 1980]. The presence of saponins has not been confirmed in the flowers of *V. thapsus* and *V. densiflorum*.

Mucilaginous polysaccharides (2-3%) consisting of neutral (arabinogalactan and xyloglucan) and acidic polysaccharides, particularly a highly-branched arabinogalactan with a β-1-6- linked galactose backbone as well as compounds composed of L-arabinose, D-galactose, D-galacturonic acid, D-glucose, D-glucuronic acid, D-mannose , L-rhamnose and D-xylose [Kraus 1987].

Other constituents include phytosterols such as β-sitosterol and stigmasterol, and the bicyclic monoterpene digiprolactone [Hein 1959], carotenoids and xanthophylls [Blohme 2007; Hänsel 2007]. Flowers of *V. phlomoides* contain 2.4% and flowers of *V. densiflorum* 1.6% of fixed oil with palmitic, linolenic and myristic acid as main components [Grzybek 1996].

CLINICAL PARTICULARS

Therapeutic indications

Common cold associated with cough or sore throat as a demulcent and/or a mild expectorant [Bradley 2006; Blohme 2007; Schilcher 2008; Wichtl 2009].

In these indications, the efficacy is plausible on the basis of long-standing use.

Posology and method of administration

Dosage

Adult daily dose: 1-1.5 g of dried drug as an infusion, one to three times daily [Bradley 2006; Blohme 2007; Schilcher 2008; Wichtl 2009].

E/S/C/O/P MONOGRAPHS

Method of administration
For oral administration.

Duration of administration
No restriction. If symptoms persist or worsen, medical advice should be sought.

Contra-indications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with normal medical practice, mullein flower should not be used during pregnancy and lactation.

Effects on ability to drive and use machines
None known.

Undesirable effects
A 33-year old man employed in the medicinal plant industry developed an airborne contact dermatitis, the severity of lesions reduced on vacations and worsened after returning to work. Of 30 herbal drugs tested, a positive reaction was observed after administration of one mixture. Testing of the individual components showed that *Verbascum densiflorum* was responsible for the allergic reaction (positive tests after 48 and 96 h). Patch testing with the plant material in 10 control patients, 5 atopics and 5 non-atopics, was negative [Castro 2006].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

Relatively few pharmacological studies on mullein preparations have been published. Therefore, reports on the pharmacological activities of relevant constituents, notably the iridioid aucubin and the phenylethanoid glycoside verbascoside (acteoside), are also included.

In vitro experiments

Antiviral activity
An aqueous mullein flower dry extract (3.7-4:1) exhibited antiviral activity against fowl plague virus, several influenza A strains, an influenza B strain and *Herpes simplex* Type-1 virus. In the virus-induced cytopathic-effect inhibition assay in Vero cells, the titre of *H. simplex* decreased from 1.7 log units inhibition of virus replication at 50 µg/mL to 2.6 log units at 350 µg/mL after 4 days. The maximum non-toxic concentration (MTC) in Vero cells was determined as 1000 µg/mL after 2 days and 500 µg/mL after 3 days incubation. Plaque reduction of 50% was observed at 190 µg/mL. Virucidal activity was demonstrated by complete inhibition of the virus-induced cytopathic effect in virus-infected Vero cells which had been exposed to the mullein flower extract (300 µg) for 4h [Slagowska 1987].

The antiviral activity against influenza viruses was tested in chorioallantoic membrane cultures, the MTC was 1400 µg/mL in this cell line. The titre of four influenza A strains and one influenza B strain decreased by 1-3 log units, with minimal effective concentration values of 250-1000 µg/mL for influenza A and 1300 µg/mL for the influenza B strain. The strongest inhibition was observed when mullein flower infusion was applied simultaneously or after the virus infection [Zgorniak-Nowosielska 1991].

In another study, combination of an aqueous dry extract (4:1) with amantadine derivatives led to a marked enhancement of the inhibitory effect on the reproduction of an influenza A strain in chick embryo fibroblast cell cultures. The most pronounced enhancement was observed for the combination with amantadine glucuronide [Serkedjieva 2000].

Verbascoside exhibited antiviral activity against respiratory syncytial virus (RSV) in the viral cytopathic effect assay (EC_{50} 0.80 µg/mL) and the plaque-neutralization assay (EC_{50} 9.7 µg/mL) compared to ribavirin as positive control (EC_{50} 1.80 µg/mL and 2.2 µg/mL respectively), but was not active against murine cytomegalovirus and herpes simplex virus type 2 [Kernan 1998].

In another study, verbascoside inhibited vesicular stomatitis virus replication by 53.6% at a concentration of 500 µg/mL in HeLA cells, but did not show any effect against herpes simplex virus type 1 or poliovirus type 1 [Bermejo 2002].

Diosmin and hesperidin inhibited rotavirus infectivity in the viral cytopathic effect assay (IC_{50} 10 µg/mL), quercetin was not active [Bae 2000] .

Antibacterial activity
Mullein flower in olive oil (not further defined) inhibited the growth of *Klebsiella pneumonia*, *Escherichia coli*, *Pseudomonas aeruginosa*, and *Staphylococcus aureus* in the disc diffusion assay, whereas no effect was observed on *Staphylococcus epidermis* or *Streptococcus pyogenes* [Turker 2002].

Cytotoxic activity
Cytotoxic activity of mullein flower in olive oil (not defined, 600 µl + 150 µL water + 750 µL *Agrobacterium tumefaciens* in PBS) was assessed with the potato disc method. The number of tumors was reduced to 26 (50% inhibition) compared to 53 for water, 60 for 50% methanol (0% inhibition) and 0 for campothecin (100% inhibition) [Turker 2002].

Aqueous mullein flower extracts (5 g in 10 mL water at 37°C or 5 g in 50 mL boiling water and evaporation to 10 mL) had a strong inhibitory effect on the elongation step of protein biosynthesis in isolated rat liver ribosomes. Incorporation of [^{14}C]-leucin into proteins was inhibited by 50% at a concentration of 5% in the incubation mixture. No effect was observed for an ethanolic mullein flower extract (no details available). Fractionation of the aqueous extracts showed that the saponin fraction inhibited elongation factors EF-1 and EF-2, whereas no effect on peptidyltransferase activity was observed. Saponins markedly inactivated ribosomes by 43% (at a dose equivalent to 20 mg mullein flower) probably by inactivation of the binding site of the elongation factors to the ribosomes [Paszkiewicz-Gadek 1990].

Antioxidant and radical-scavenging activity
A 60% ethanolic extract (2g dried flowers in 25 mL, flavonoids 287 mg/L, carotenoids 415 mg/L) exhibited antioxidant activity equivalent to 2.5 mg/mL of ascorbic acid [Mariassyova 2006].

Radical scavenging activity
Forsythoside B and verbascoside showed scavenging activity on DPPH- and on peroxyl radicals comparable to chlorogenic

acid as a positive control, but lower than chlorogenic acid on hydroxyl radicals and in the ferric-reducing assay. Superoxide anions were scavenged to 50% by forsythoside B at 4.2 µg/mL and by verbascoside at 17.5 µg/mL [Deepak 1999; Georgiev 2011]. Verbascoside at 100 µM also significantly ($p<0.05$) reduced superoxide anion formation in LPS and LPS/interferon-γ stimulated human myelomonocytic leukaemia cells [Speranza 2010].

Verbascoside at 50-200 µM inhibited LPS-stimulated NO formation in murine macrophages by 12-59% ($p<0.001$) and by 11-56% ($p<0.001$) in mouse peritoneal exudate macrophages, compared to 64% and 70% respectively by polymixin B (5 µg/mL) as positive control. Expressions of inducible iNOS mRNA, iNOS protein level and iNOS activity in LPS-stimulated cells were not affected. A donor-induced NO reduction by 14-57% ($p<0.001$) was observed at 2-10 µM [Xiong 2000]. In another study, however, verbascoside at 100 µM significantly reduced expression of iNOS mRNA and protein as well as of nuclear NF-κB protein in LPS and LPS / interferon-γ stimulated human myelomonocytic leukaemia cells ($p<0.05$) [Speranza 2010].

Antiinflammatory activity
Aucubin inhibited Ag-induced TNF-α and IL-6 production and expression in RBL-2H3 mast cells in a dose dependent manner with an IC_{50} of 0.10 and 0.19 µg/mL respectively. Maximal inhibition of TNF-α was 73.0% and of IL-6 88.8% [Jeong 2002].

Other activities
A mullein flower infusion (4.6 g/100 mL water) did not affect mucociliary transport velocity in isolated ciliated epithelium from the frog oesophagus 90 s after application at a dose of 200 µl [Müller-Limmroth 1980].

In vivo experiments

Antiinflammatory activity
Aucubin administered orally at 100 mg/kg b.w. inhibited carrageenan-induced rat paw oedema by 33% after 3 hours ($p<0.01$) compared to 44% inhibition by indomethacin (7 mg/kg) as positive control. TPA-induced mouse ear oedema was inhibited by 80% after 4 hours ($p<0.01$) when administered topically at 1 mg/ear (indomethacin: 87% at 0.5 mg/ear). Catalpol did not show significant activity [Recio 1994].

In another study, aucubin administered i.p. at 5 mg/kg b.w. inhibited carrageenan-induced rat paw oedema by 37.9% compared to 49.5% by diclofenac as positive control ($p<0.001$). Both compounds inhibited the inflammatory reaction dose dependently after oral (1.0-10.0 mg/kg) or i.p. (0.5-10.0 mg/kg) administration ($p<0.01$) [Haznagy-Radnai 2012].

Oral administration of verbascoside (200 mg/kg b.w.) inhibited carrageenan-induced hind paw oedema in mice by 19.3-26.9% ($p<0.05$), aucubin (125 mg/kg) by 25.0-33.3% ($p<0.01$), catalpol (19.6 mg/kg) by 11.3-11.5% and indomethacin (10 mg/kg) as positive control by 35.1-45.9% [Kupeli 2007; Akdemir 2011].

In an experimental model of periodontitis in rats verbascoside, administered orally at a dose of 2 mg/kg b.w. daily for 8 consecutive days, significantly decreased several markers of inflammation in gingivomucosal tissue: myeloperoxidase activity ($p<0.001$), malondialdehyde formation ($p<0.01$), NFκB expression ($p<0.01$), iNOS expression ($p<0.01$), nitration of tyrosine residues, activation of the nuclear enzyme poly(ADP-ribose)polymerase ($p<0.01$), expression of apoptosis-inducing proteins Bax and Bcl-2 ($p<0.01$), as well as the degree of gingivomucosal tissue injury [Paola 2011].

In a model of dinitrobenzene sulfonic acid (4 mg per mouse) induced inflammatory bowel disease, the antiinflammatory effect of verbascoside (administered by gavage at 2 mg/kg b.w. every 24 h for 3 days) in mice lacking peroxisome proliferator-activated receptor-α compared to wild-type mice was studied. Verbascoside-mediated antiinflammatory activity was significantly weakened in the animal group without the receptor ($p<0.01$). This was highlighted by the inhibition of myeloperoxidase activity, of intestinal permeability, and of colon injury [Esposito 2010].

Analgesic and antinociceptive acitivity
Verbascoside inhibited acetic acid-induced writhing and tail pressure pain in mice when administered orally at 300 mg/kg b.w. and 100 mg/kg b.w. respectively ($p<0.001$) [Nakamura 1997].

In mice, p-benzoquinone -induced writhings were inhibited by verbascoside by 32.4% ($p<0.01$) at a dose of 200 mg/kg b.w., the same dose of acetylsalicylic acid as positive control inhibited writhings by 58.6% ($p<0.001$); verbascoside did not induce any apparent gastric damage or acute toxicity. The inhibition ratio obtained by administration of aucubin was 35.8% ($p<0.05$) at a dose of 125.1 mg/kg b.w.; after administration of catalpol at a dose of 19.6 mg/kg b.w. writhings were inhibited by 19.4% [Kupeli 2007; Akdemir 2011].

The antihyperalgesic activity of verbascoside was studied in a paw-pressure test in rats. Neuropathic pain was either produced by a chronic constriction injury of the sciatic nerve (CCI) or by an intra-articular injection of sodium monoiodoacetate (MIA). Verbascoside administered i.p. at a dose of 100 mg/kg b.w. significantly reverted hyperalgesia in both groups ($p<0.05$). In the CCI rats, the effect started 15 min after treatment and lasted 45 min, in MIA rats it started after 15 min and lasted 30 min. When administered orally at doses of 300 and 600 mg/kg b.w. the antihyperalgesic effect started 15 min after administration and was still significant after 60 min ($p<0.05$). The pain threshold in animals with non neuropathic pain was not influenced by verbascoside after i.p administration of 50-100 mg/kg b.w. or 300-600 mg/kg b.w. orally [Isacchi 2011].

Wound healing activity
In the linear incision wound model in mice, the wounds were treated topically once a day for nine consecutive days with 0.5 g of a preparation containing 1% verbascoside, vehicle, or a commercial product containing 1% *Centella asiatica* dry extract (positive control). The tensile strength measured on day 10 increased by 25.8% ($p<0.05$) after treatment with the verbascoside containing preparation compared to the vehicle, and 54.5 % ($p<0.001$) after treatment with the positive control. In the circular excision wound model, treatment with verbascoside reduced the wound area by 28.25% ($p<0.05$) at day 10 and 40.52% (0.01) at day 12, compared to the positive control (72.24-100%, $p<0.001$) [Akdemir 2011].

Clinical studies
No clinical studies have been published on preparations of mullein flower.

Pharmacokinetic properties
No data available.

Preclinical safety data
A lyophilized mullein flower infusion (3.7-4:1) did not show toxic effects in Vero cells up to a concentration of 1000 µg/mL at 48 h incubation and up to 500 µg/mL at 72 h incubation. In chick embryo fibroblast cells the maximal non-toxic conentration was 600 µg/mL mullein flower infusion [Slagowska 1987; Zgorniak-Nowosielska 1991].

Verbascoside did not effect gross behaviour or motor coordination of rats in the rota-rod test when administered p.o. at a dose of 1000 mg/kg b.w. [Isacchi 2011]

Genotoxicity of verbascoside
Verbascoside significantly ($p<0.05$) reduced cell viability at 0.01-1 mM and mitotic index at 0.005-0.1 mM in mitogen-stimulated human lymphocytes. It induced a significant and concentration related increase of chromosome aberrations, an increase in the percentage of aberrant cells ($p<0.01$) and in sister chromatid exchanges [Santoro 2008].

Clinical safety data
No data available.

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

It is a great pleasure for me to introduce the online era of ESCOP Monographs. Interest in herbal medicinal products continues to stimulate research on herbal substances and the body of knowledge in this field is steadily growing. ESCOP takes account of this by preparing new monographs and - as the only organisation in the field at the moment - particularly through regular revision of our published monographs. In order to provide readers and authorities with balanced compilations of scientific data as rapidly as possible, ESCOP Monographs will be published online from now on. This contemporary way of publishing adds further momentum to ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to the members of the Scientific Committee, external experts and supervising editors, and to Peter Bradley, the final editor of every monograph published up to March 2011. All have voluntarily contributed their time and scientific expertise to ensure the high standard of the monographs.

Liselotte Krenn
Chair of the Board of ESCOP

PREFACE

Over the 15 years since ESCOP published its first monographs, initially as loose-leaf documents then as two hardback books, ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products. The Second Edition, published in 2003 with a Supplement in 2009, covered a total of 107 herbal substances.

The monograph texts are prepared in the demanding format of the Summary of Product Characteristics (SPC), a standard document required in every application to market a medicinal product for human use within the European Union and ultimately providing information for prescribers and users of individual products.

As a change in style, literature references are now denoted by the name of the first author and year of publication instead of reference numbers; consequently, citations at the end of a monograph are now in alphabetical order. This is intended to give the reader a little more information and perspective when reading the text.

Detailed work in studying the pertinent scientific literature and compiling draft monographs relies to a large extent on the knowledge, skills and dedication of individual project leaders within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are appraised by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved, but it is a time-consuming process.

To accelerate the publication of new and revised monographs ESCOP has therefore decided to publish them as an online series only, commencing in 2011. We trust that rapid online access will prove helpful and convenient to all users of ESCOP Monographs.

As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

Front cover
Title page
Verso
Foreword and Preface
Notes for the Reader
Abbreviations
The monograph text
Back cover

Information on the member organizations and people involved in ESCOP's activities can be found on the website (www.escop.com):

Board of Directors of ESCOP

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency

i.p.	intraperitoneal
IPSS	International Prostate Symptom Score
i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-kB	necrosis factor kappa-B
NO	nitric oxide
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TGF-b	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

VIOLAE HERBA CUM FLORE 2015

Wild Pansy (Flowering Aerial Parts)

DEFINITION

Wild pansy consists of the dried flowering aerial parts of *Viola arvensis* Murray and/or *Viola tricolor* L. It contains not less than 1.5 per cent of flavonoids, expressed as violanthin ($C_{27}H_{30}O_{14}$; M_r 578.5) (dried drug).

The material complies with the monograph of the European Pharmacopoeia [Wild Pansy].

Fresh material may also be used provided that when dried it complies with the monograph of the European Pharmacopoeia.

CONSTITUENTS

The characteristic constituents include

- Flavonoids (up to 2.9%), mainly rutin (up to 1%) and other flavonol-*O*-glycosides together with flavone-*C*-glycosides, principally apigenin di-*C*-glycosides including violanthin (up to 0.8%), violarvensin (up to 0.7%) and vicenin-2, and the luteolin mono-*C*-glucosides isoorientin and orientin [Fraisse 2001, Carnat 1998, Wagner 1972, Glasl 1984, Hänsel 1994, Bradley 2006, Vukics 2008a]. The flowers also contain anthocyanins such as violanin [delphinidin 3-(6-*p*-coumaroyl-rhamnosylglucoside)-5-glucoside] [Saito 1983].
- Phenolic acids (up to 0.5%), mainly salicylic acid and its derivatives methyl salicylate and violutin (methyl salicylate arabinosylglucoside) [Fraisse 2001, Komorowski 1983, Hänsel 1994].
- Carotenoids of the xanthophyll type (up to 0.1%) in the yellow flowers, principally 9-*cis*-violaxanthin (ca. 50%) and all-*trans* violaxanthin (ca. 30%) together with other *cis*- and di-*cis*-violaxanthins. They are mainly present as di-esters, esterified with saturated C_{12}-C_{18} fatty acids and/or b-hydroxy C_{12}-C_{18} fatty acids [Molnar 1980 & 1986, Hansmann 1982].
- Polysaccharides, from ca. 10% [Franz 1969, Zabaznaya 1985] to ca. 25% [Fraisse 2001], consisting mainly of glucose, galactose and arabinose together with xylose and galacturonic acid.
- Cyclotides (about 0.02%): these are macrocyclic peptides containing about 30 amino acids linked in a head-to-tail cyclic backbone constrained by 3 disulfide bonds. The proteins violapeptide I [Schöpke 1993, Göransson 2004] and varvs A-H [Claeson 1998, Göransson 1999] have been isolated from *V. arvensis* while vitri A, varv A and varv E have been isolated from *V. tricolor* [Svangard 2004].

Other constituents include tannins, ascorbic acid, tocopherol and minerals (mainly potassium salts) [Rimkiene 2003, Fraisse 2001, Hänsel 1994, Wichtl 2001].

Saponins were not detected in *V. tricolor* [Schöpke 1993] nor in *V. arvensis* [Schöpke 1993, Fraisse 2001], contrary to an earlier report of about 5% saponins in *V. tricolor* [Tamas 1981].

CLINICAL PARTICULARS

Therapeutic indications

Skin disorders such as eczema, seborrhoea, impetigo and acne, as well as cradlecap and nappy-rash of infants [Bradley 2006, Rimkiene 2003, Hänsel 1994, Wichtl 2001, Van Hellemont 1988, Schilcher 2006].

In these indications, the efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Internal use
Adults: 1.5-4 g of the drug as an infusion three times daily [Bradley 2006, Hänsel 1994, Wichtl 2001]; fluid extract (1:1, ethanol 25%), 2-4 ml three times daily [Bradley 2006]; dry extract (6:1), 2-4 g daily [Van Hellemont 1988].

Children: proportion of adult daily dose according to age or body weight.

External use
3-4 g of the drug in 150 ml of hot water as a compress or poultice, several times daily [Bradley 2006, Hänsel 1994].

Method of administration
For oral administration and local application.

Duration of administration
No restriction.

Contra-indications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, the product should not be used during pregnancy or lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
None reported.

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Antimicrobial activity
An infusion, a decoction and an ethanolic extract from *V. tricolor* herb exhibited antimicrobial activity against various Gram-positive and Gram-negative bacteria and the fungus *Candida albicans* with MIC and MBC ranging from 0.15 to 5 mg/ml [Witkowska-Banaszczak 2005].

Cytotoxic activity
A 70% ethanolic extract of *V. tricolor* herb and its ethyl acetate, butanol and water fractions were examined for cytotoxic potential on MCF-7 human breast cancer cells, Neuro2a mouse neuroblastoma and normal murine fibroblast cells. The ethyl acetate fraction significantly inhibited cell proliferation in MCF-7 (about 50% ; $p<0.001$ at 200 µg/mL) and in Neuro2a cells (about 25% ; $p<0.01$ at 200 µg/mL). In contrast it was less toxic in normal cells at concentrations up to 400 µg/mL. Further investigation showed induction of apoptosis by increased sub-G1 peak, Bax/Bcl-2 ratio and cleaved caspase-3 level [Sadeghnia 2014].

An aqueous fraction of a dichloromethane : methanol (1:1) extract of *V. tricolor* inhibited proliferation of activated lymphocytes by reducing IL-2 cytokine secretion, as well as reducing production of IFN-g and TNF-a. IL-2 receptor expression and degranulation capacity remained unaffected. Bioassay-guided purification led to 2 active fractions containing cyclotides [Hellinger 2014].

In initial cytotoxicity screening the polypeptide fraction of *V. arvensis* exhibited cytotoxic activity against human embryonic lung tumour cells and T cells. In further screening the fraction exhibited dose-dependent cytotoxic activity against 10 human cancer cell lines with IC_{50} values of 15-45 µg/ml [Lindholm 2002].

The isolated cyclotides varv A and varv F were tested against the same 10 cell lines and were also found to have cytotoxic activity, with IC_{50} values of 2.7-6.4 µM and 2.6-7.4 µM respectively. When varv A was subsequently tested in lymphocytic leukaemia cells from patients and in healthy lymphocytes it exhibited selective toxicity against the leukaemia cells (IC_{50} of 1.34 µM, compared to 12.13 µM in healthy lymphocytes) [Lindholm, Göransson 2002].

Correlation analysis showed that the activity profiles of the polypeptide fraction and the two isolated cyclotides differed significantly from those of antitumour drugs in clinical use, suggesting a new mechanism for cytotoxicity [Lindholm, Gullbo 2002; Lindholm, Göransson 2002].

The cyclotides vitri A, varv A and varv E (isolated from *V. tricolor*) exhibited dose-dependent cytotoxic activity against human lymphoma and myeloma cancer cell lines with IC_{50} values of 0.6 and 1 µM respectively for vitri A, 6 and 3 µM respectively for varv A, and 4 µM in both cell lines for varv E, compared to 0.1 µM in both cell lines for doxorubicin [Svangard 2004].

Other activities
A 50%-methanolic extract from *V. tricolor* was tested for antispasmodic activity using isolated guinea-pig ileum. However, at concentrations ranging from 100 to 800 µg/ml the extract actually exhibited spasmogenic activity [Izzo 1996].

A 70% ethanolic extract of *V. tricolor* flower showed antioxidant activity in the DPPH assay in a dose-dependent manner (IC_{50} 16.0 µg/mL versus 16.6 µg/mL for ascorbic acid) [Piana 2013].

Flavonoid fractions from a methanolic extract and rutin demonstrated antioxidant activity in the Trolox (IC_{50} from 0.12 µg/mL to 17.9 µg/mL) and DPPH assays (IC_{50} from 4.0 µg/mL to 53.0 µg/mL) [Vukics 2008b].

An ethyl acetate fraction from a 70% ethanolic extract of *V. tricolor* herb significantly decreased the diameter of blood vessels on chicken chorioallantoic membrane ($p<0.05$ at 40 µg/egg), while the number of newly formed blood vessels was not suppressed [Sadeghnia 2014].

In vivo experiments

The antinociceptive and anti-inflammatory effect of a gel containing a dried ethanolic (70%) extract of *V. tricolor* flower (at 1%, 3% and 10%) was investigated in adult male Wistar rats with UVB-induced sunburn. The extract (3% in gel) prevented static (100%) and dynamic (49%) mechanical allodynia and

paw oedema (61%). The induced increase in myeloperoxidase activity was inhibited (89%) by the gel (3%). The results were comparable to those obtained with a 1% silver sulfadiazine cream [Piana 2013].

A tincture of *V. tricolor* herb (1:10, ethanol 70%) orally administered to adult male rats (1 mL/100 g) showed a moderate diuretic effect (diuretic index: 1.103; saluretic index Na^+: 1.181; saluretic index K^+: 1.365) [Toiu 2009].

In old experiments wild pansy showed anti-inflammatory activity in animals [Papay 1987] and improvement of induced eczema in rats when the fresh herb was added to their diet for 2 months [Hänsel 1994].

Pharmacological studies in humans
No data available.

Clinical studies
No data available.

Pharmacokinetic properties
No data available.

Preclinical safety data
No data available.

Clinical safety data
No data available.

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.

Important Note: Medical knowledge is ever-changing. As new research and clinical experience broaden our knowledge, changes in treatment may be required. In their efforts to provide information on the efficacy and safety of herbal drugs and herbal preparations, presented as a substantial overview together with summaries of relevant data, the authors of the material herein have consulted comprehensive sources believed to be reliable. However, in view of the possibility of human error by the authors or publisher of the work herein, or changes in medical knowledge, neither the authors nor the publisher, nor any other party involved in the preparation of this work, warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for results obtained by the use of such information. Readers are advised to check the product information included in the package of each medicinal preparation they intend to use, to be certain that the information contained in this publication is accurate and that changes have not been made in the recommended dose or in the contraindications for administration.

FOREWORD

On behalf of my colleagues in ESCOP it is my great pleasure here to mark the successful online programme for the publication of ESCOP Monographs. Interest in herbal medicinal products and their ingredients continues to stimulate research and the body of knowledge in this field is steadily growing. ESCOP takes full account of this in producing balanced compilations of new evidence, in the form of new ESCOP monographs and by regular revisions of previously published monographs. Our online publication, since 2011, ensures that readers and authorities are updated as rapidly as possible, and builds further on ESCOP's endeavours in the harmonization of European standards for herbal medicinal products.

The Board of ESCOP wishes to express its sincere gratitude to all members of the Scientific Committee, to external experts and to supervising editors. All have contributed their time and scientific expertise voluntarily to ensure the high standard of the monographs.

Dr. Tankred Wegener
Chair of the Board of ESCOP

PREFACE

ESCOP published its first monographs in the 1990's, initially as loose-leaf documents, then as two hardback books in 2003 and 2009. ESCOP Monographs have achieved a reputation for well-researched, comprehensive yet concise summaries of available scientific data pertaining to the efficacy and safety of herbal medicinal products.

The monograph format closely resembles the Summary of Product Characteristics (SPC) template, which is the basis for the information required for authorized/registered medicinal products, e.g. in the package leaflet, as laid down in Directive 2001/83/EC of the European Union.

Detailed work in studying the relevant scientific literature and compiling draft monographs relies on the knowledge, skills and dedication of individual project leaders and their colleagues within ESCOP Scientific Committee, as well as invited experts. After discussion and provisional acceptance by the Committee, draft monographs are reviewed by an eminent Board of Supervising Editors and all comments are taken into account before final editing and approval. In this way a wide degree of consensus is achieved.

We trust that rapid online access is helpful and convenient to all users of ESCOP Monographs. As always, ESCOP is indebted to the many contributors involved in the preparation of monographs, as well as to those who provide administrative assistance and hospitality to keep the enterprise running smoothly; our grateful thanks to them all.

NOTES FOR THE READER

From 2011 new and revised *ESCOP Monographs* are published as an online series only. Earlier monographs are available in two books, *ESCOP Monographs* Second Edition (2003) and the Second Edition *Supplement 2009*, but are not available online for copyright reasons.

After purchase of a single monograph, the specific items to be downloaded are:

ABBREVIATIONS used in ESCOP monographs

AA	arachidonic acid
ABTS	2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)
ACE	angiotensin converting enzyme
ADP	adenosine diphosphate
ALAT or ALT	alanine aminotransferase (= SGPT or GPT)
ALP	alkaline phosphatase
anti-IgE	anti-immunoglobulin E
ASA	acetylsalicylic acid
ASAT or AST	aspartate aminotransferase (= SGOT or GOT)
ATP	adenosine triphosphate
AUC	area under the concentration-time curve
BMI	body mass index
BPH	benign prostatic hyperplasia
b.w.	body weight
cAMP	cyclic adenosine monophosphate
CAT	catalase
CCl_4	carbon tetrachloride
CI	confidence interval
C_{max}	maximum concentration of a substance in serum
CNS	central nervous system
CoA	coenzyme A
COX	cyclooxygenase
CSF	colony stimulating factor
CVI	chronic venous insufficiency
CYP	cytochrome P450
d	day
DER	drug-to-extract ratio
DHT	dihydrotestosterone
DMSO	dimethyl sulfoxide
DNA	deoxyribonucleic acid
DPPH	diphenylpicrylhydrazyl
DSM	Diagnostic and Statistical Manual of Mental Disorders (American Psychiatric Association)
ECG	electrocardiogram
ED_{50}	effective dose in 50% of cases
EDTA	ethylenediamine tetraacetate
EEG	electroencephalogram
EMA	European Medicines Agency
ENT	ear, nose and throat
ER	oestrogen receptor
ERE	oestrogen-responsive element
FSH	follicle-stimulating hormone
GABA	gamma-aminobutyric acid
Gal	galactose
GFR	glomerular filtration rate
GGTP	gamma-glutamyl transpeptidase
GOT	glutamate oxalacetate transaminase (= SGOT)
GPT	glutamate pyruvate transaminase (= SGPT)
GSH	glutathione (reduced)
GSSG	glutathione (oxidised)
HAMA	Hamilton Anxiety Scale
12-HETE	12-hydroxy-5,8,10,14-eicosatetraenoic acid
HDL	high density lipoprotein
HIV	human immunodeficiency virus
HMPC	Committee on Herbal Medicinal Products (of the EMA)
HPLC	high-performance liquid chromatography
5-HT	5-hydroxytryptamine (= serotonin)
IC_{50}	concentration leading to 50% inhibition
ICD-10	International Statistical Classification of Diseases and Related Health Problems, Tenth Revision
ICH	The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use
ICSD	International Classification of Sleep Disorders
IFN	interferon
IL	interleukin
i.m.	intramuscular
iNOS	inducible nitric oxide synthase
INR	International Normalized Ratio, a measure of blood coagulation (clotting) tendency
i.p.	intraperitoneal
IPSS	International Prostate Symptom Score

i.v.	intravenous
kD	kiloDalton
KM Index	Kuppermann Menopausal Index
kPa	kiloPascal
LC-MS	liquid chromatography-mass spectrometry
LD_{50}	the dose lethal to 50% of animals tested
LDH	lactate dehydrogenase
LDL	low density lipoprotein
LH	luteinizing hormone
5-LOX	5-lipoxygenase
LPS	lipopolysaccharide
LTB_4	leukotriene B_4
M	molar (concentration)
MAO	monoamine oxidase
MBC	minimum bactericidal concentration
MDA	malondialdehyde
MFC	minimum fungicidal concentration
MIC	minimum inhibitory concentration
Mr	molecular
MRS	Menopause Rating Scale
MRSA	methicillin-resistant *Staphylococcus aureus*
MTD	maximum tolerated dose
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
MW	molecular weight
NBT	nitro blue tetrazolium
NF-κB	nuclear factor kappa-B
NO	nitric oxide
NOAEL	no observed adverse effect level
NOS	nitric oxide synthase
n.s.	not significant
NSAID	non-steroidal anti-inflammatory drug
ovx	ovariectomy or ovariectomized
ORAC	oxygen radical absorbance capacity
PA	pyrrolizidine alkaloid
PAF	platelet activating factor
PARP	poly (ADP-ribose) polymerase
PBMC	peripheral blood mononuclear cells
PCR	polymerase chain reaction
PEG	polyethylene glycol
PGE	prostaglandin E
Pgp	P-glycoprotein
PHA	phythaemagglutinin
p.o.	per os
POMS	profile of mood states
PVPP	polyvinylpolypyrrolidone
RANKL	receptor activator of nuclear factor kappa-B ligand
RNA	ribonucleic acid
ROS	reactive oxygen species
RT-PCR	reverse transcription polymerase chain reaction
s.c.	subcutaneous
SCI	spinal cord injury
SERM	selective oestrogen receptor modulator
SGOT or GOT	serum glutamate oxalacetate transaminase (= ASAT or AST)
SGPT or GPT	serum glutamate pyruvate transaminase (= ALAT or ALT)
SHBG	sex hormone binding globulin
SOD	superoxide dismutase
SSRI	selective serotonin reuptake inhibitor
STAI	state-trait anxiety inventory
$t_{1/2}$	elimination half-life
TBARS	thiobarbituric acid reactive substances
TC	total cholesterol
TGF-β	transforming growth factor-beta
TNF	tumour necrosis factor
TPA	12-*O*-tetradecanoylphorbol-13-acetate
URT	upper respiratory tract
URTI	upper respiratory tract infection
UTI	urinary tract infection
VAS	visual analogue scale
VLDL	very low density lipoprotein

VITIS VINIFERAE FOLIUM

2020

Red Vine Leaf

DEFINITION

Red vine leaf consists of the dried leaves from cultivars of *Vitis vinifera* L. known as "teinturiers" and characterized by black grapes and red pulp. It contains not less than 4.0 per cent of total polyphenols and 0.2 per cent of anthocyanins, expressed as cyanidin 3-glucoside ($C_{21}H_{21}O_{11}$; Mr 449).

The material complies with the monograph of the Pharmacopée Française [Vigne rouge – Vitis vinifera].

Note: The leaves turn partially or completely red in autumn. Examples of suitable cultivars are the teinturiers Alicante and Gamay Fréaux [Bruneton 1995; Boucheny 1990].

CONSTITUENTS

The characteristic constituents are phenolic compounds:

- Flavonoids (up to 3.5%), the most abundant being quercetin glycosides (such as quercetin 3-glucuronide, isoquercitrin and hyperoside) and kaempferol 3-glucoside [Ahmed 2015; Andelković 2015; Schneider 2007, 2008; Bombardelli 1995; Boucheny 1990; Diaz 1989].
- Anthocyanins (0.1-1.5%) composed principally of 3-glucosides of peonidin, malvidin and cyanidin [Schneider 2007, 2008; Ezzilli 1997; Boucheny 1990; Laparra 1989; Darné 1988; Wenzel 1987]. The anthocyanin content of the leaves increases during grape maturation then decreases until leaf fall [Ezzilli 1997; Darné 1988].
- Condensed tannins (proanthocyanidins, about 4%), mainly the procyanidin dimers B1 and B2 together with trimers and procyanidin galloylesters [Ahmed 2015; Andelković 2015; Schneider 2007, 2008; Hmamouchi 1997; Boucheny 1990; Bourzeix 1986].
- Other phenolic constituents including flavan-3-ols (free and as galloyl esters), hydroxycinnamic acids (free and esterified with tartaric acid) and other phenolic acids such as p-hydroxybenzoic acid, gallic acid and syringic acid [Ahmed 2015; Andelković 2015; Bombardelli 1995; Bruneton 1995; Boucheny 1990].

CLINICAL PARTICULARS

Therapeutic indications

Internal use

Aqueous dry extract (4-7:1)
Treatment of symptoms of chronic venous insufficiency (CVI) [Butcher 2006; Kalus 2004; Schaefer 2003; Antignani 2001; Kiesewetter 2000] at stages I-II as defined by Widmer and at stages 2-4a [Rabe 2011; Monsieur 2006] as defined by CEAP classification [Eklöff 2004; Meissner 2007].

Stages of chronic venous insufficiency (CVI)
according to Widmer's classification [Antignani 2001, Widmer 1978]

Stage I
Dilated subcutaneous veins, corona phlebectatica paraplantaris, oedema.

Stage II
Trophic lesions (dermatitis, dermatoliposclerosis, white atrophy).

Stage III
Active or healed leg ulcer.

E/S/C/O/P
MONOGRAPHS

CEAP classification for chronic venous disorders (CVD) [Eklöf 2004; Porter 1995; Perrin 2005; Meisner 2007]

C0: no visible or palpable signs of venous disease
C1: telangiectasies or reticular veins
C2: varicose veins
C3: oedema
C4a: pigmentation or eczema
C4b: lipodermatosclerosis or atrophie blanche
C5: healed venous ulcer
C6: active venous ulcer
S: symptomatic, including ache, pain, tightness, skin irritation, heaviness, muscle cramps, and other complaints attributable to venous dysfunction
A: asymptomatic

Other preparations
Symptomatic treatment of problems related to varicosis such as painful and heavy legs, as well as haemorrhoids [Fournier 1948; Valnet 1992; Boullard 2001; Van Hellemont 1986]. In these indications, the efficacy is plausible on the basis of human experience and long-standing use.

External use
Topical treatment of varicosis and couperosis [Vanaclocha 2003]. In these indications, the efficacy is plausible on the basis of human experience and long-standing use.

Posology and method of administration

Dosage

Internal use
360-720 mg of red vine leaf aqueous dry extract (4-7:1) daily [Yu 2014; Perrinjaquet-Moccetti 2013; Rabe 2011; Kalus 2004; Kiesewetter 2000].

10 g of dried leaf in 250 mL of water as an infusion, 2-4 cups per day [Elias 1993; Valnet 1992]; 10 mL of fluid extract, once daily [Valnet 1992; Van Hellemont 1986].

External use
As a bath or footbath, a decoction of 60-80 g of dried leaf per litre of water [Vanaclocha 2003].

Method of administration
For oral administration or local application.

Duration of administration
No restriction.

Contra-indications
None known.

Special warnings and special precautions for use
None required.

Interaction with other medicaments and other forms of interaction
None reported.

Pregnancy and lactation
No data available. In accordance with general medical practice, red vine leaf should not be used internally during pregnancy and lactation without medical advice.

Effects on ability to drive and use machines
None known.

Undesirable effects
Mild gastrointestinal complaints have been reported [Kiesewetter 2000].

Overdose
No toxic effects reported.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic properties

In vitro experiments

Protection of venous endothelium
An aqueous dry extract (4-6:1, containing 3.3% of quercetin 3-glucuronide and 1.7% of isoquercitrin) and isolated quercetin 3-glucuronide were tested in the presence of platelets and polymorphonuclear granulocytes (PMN) for protective effects on venous endothelial cells (VEC) cultivated on porous filters to form confluent monolayers. The extract strongly inhibited the opening of intercellular clefts in the endothelial barrier caused by release products of the activated platelets and PMN. VEC monolayers pre-incubated with 50 µM quercetin 3-glucuronide for 1 or 7 days were considerably more resistant to the deleterious effects of platelet/PMN release products than VEC layers maintained in the absence of the flavonoid. The extract prevented the increase in hydraulic conductivity provoked by products released from activated blood cells [Nees 2003].

Antiherpetic activity
Various preparations of red vine leaf were tested on *Herpes simplex* virus type I (HSV-1): cryoground powder, an aqueous dry extract (1:5), filtered juice (1 mL corresponding to 3 g of fresh leaf or 600 mg of dried leaf), aqueous dry extracts prepared by maceration at 20°C or 37°C, aqueous dry extract prepared by decoction and a methanolic extract. Antiherpetic activity was determined by measuring inhibition of cytopathogenic effects of HSV-1. Extracts prepared with water at low temperature were the most active ones. Total protection against HSV-1 at a concentration of $10^3 \times ID_{50}$/50 µl (ID = the infectious dose) was obtained with cryoground powder at 50 mg/mL, the aqueous dry extract at 20 mg/ml or pure filtered juice at 0.125 mL/mL [Girre 1990].

Antispasmodic activity
Antispasmodic activity equivalent to that of 1 µg of papaverine was exerted on isolated guinea pig ileum by 0.5-1 mg of a red vine leaf infusion and 10-20 µg of a hydroalcoholic dry extract (50-80% V/V) [Abeles 1962].

Antiparasitic and antimicrobial activity
An aqueous and an ethanolic extract (not further specified), containing 3.99 mg/g and 5.0 mg/g of anthocyanins respectively, demonstrated IC_{50} values of 12.65 mg/mL and 108.9 mg/mL respectively against *Leishmania infantum*. The ethanolic extract destroyed cytoplasmic and nuclear membranes of the parasite and altered the overall shape of the host cell [Mansour 2013].

Methanolic soft extracts (not further specified, containing 2.1 to 2.6 mg/g of flavonoids) alone or in an ointment showed antibacterial activity against *Escherichia coli*, *Proteus mirabilis* and *Bacillus cereus*, but no activity against *Candida albicans* and *Aspergillus brasicalus* [Selka 2013].

Extracts (methanol/acetone/water/acetic acid: 30/42/27.5/0.5: V/V/V/V) showed stronger antimicrobial activity against Gram positive bacteria strains than against Gram negative bacterial strains and yeast [Andelković 2015].

Against *Salmonella typhimirium*, an ethanolic extract (not further specified) showed an MIC value of 6.25 µg/mL, whereas MIC values for a methanolic and an aqueous extract (not further specified) were 50 and less than 400 µg/mL respectively. Against *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Klebsiella pneumoniae* and *C. albicans* MIC values were between 12.5 and 200 µg/mL for the ethanolic extract, whereas MIC values for methanolic and aqueous extracts were between 50 and 400 µg/mL and 100 and less than 400 µg/mL respectively [Ceyhan 2012].

Anti-inflammatory activity
An aqueous extract (DER ca 4:1), containing 146.3 mg/g of total phenols, 4.3 mg/g of anthocyanin-3-glucoside and 87.09 mg/g of flavonoids, inhibited TNFα-induced IL-8 secretion (IC_{50} = 56.85 µg/mL) and IL-8 promotor activity in human epithelial gastric (AGS) cells dose-dependently (IC_{50} = 9.51 µg/mL).

In AGS cells treated with increasing concentrations of the extract and with TNFα (10 ng/mL), it was shown that the NF-κB pathway was inhibited by interfering NF-κB driven transcription and nuclear translocation with IC_{50} values of 17.01 and 23.55 µg/mL respectively. After i*n vitro* gastrointestinal digestion, the NF-κB translocation was inihibited to a lesser extent with an IC_{50} of 74.25 µg/mL, whereas the NF-κB driven transcription was not significantly changed.

In Caco-2 cells, the extract inhibited TNFα-induced IL-8 promoter activity in a dose-dependent manner (IC_{50} = 2.41 µg/mL) and inhibited the NF-κB pathway by interfering with NF-κB-driven transcription and nuclear translocation induced by TNFα with IC_{50} values of 2.65 and 34.49 µg/mL respectively. After gastric hydrolysis, these effects were suppressed. Before *in vitro* digestion, the extract inhibited IL-8 secretion with an IC_{50} of 96.1 µg/mL, whereas after *in vitro* digestion, this effect was observed at 100 µg/mL. Moreover, no effect was shown on the promoter [Sangiovanni 2015].

Antioxidant activity
An ethanolic extract (not further specified, 70% V/V) exhibited IC50 values of 17.85 ± 0.52 µg/mL and 3.79 ± 0.09 µg/mL in the DPPH and ABTS assays respectively [Antonyan 2014].

An aqueous dry extract (DER 4-6:1) showed an IC50 of 13.4 µg/mL in the DPPH radical scavenging assay [Ahmed 2015].

An aqueous extract containing 63% of flavonoids, at 100 µM, significantly ($p<0.001$) increased endothelial nitrite oxide synthase serine 1177 phosphorylation in HUVEC and in red blood cells (RBC) after 0.5 h. Nitrite concentration in HUVEC medium significantly increased after 0.5 h ($p<0.005$) until 24 h ($p< 0.001$), whereas it decreased in RBC medium at 0.5 h and 1 h ($p<0.05$).

After 30 min, the extract significantly ($p<0.01$) decreased ROS/RNS content compared to control in HUVEC with and without tert-butylhydroperoxide (THBP) (1 mM) added to induce oxidative stress. In RBC, ROS/RNS content was significantly reduced by the extract alone ($p<0.05$ compared to control) and by the extract added with THBP ($p<0.01$ compared with THBP alone).

In living HUVEC, the NO signal was significantly ($p<0.05$) increased after incubation with the extract for 30 min, compared to control. ROS/RNS content was significantly reduced by the extract and THPB (1µM) ($p<0.001$) compared to THBP alone. Superoxide signal was also significantly decreased by the extract alone ($p<0.001$ compared to control) or added with THBP vs THBP alone ($p<0.001$). Compared to control, after incubation with the extract, Cu^{2+} reduction significantly increased in HUVEC cell culture medium ($p<0.001$), in lysed HUVEC ($p<0.01$), in plasma fraction $p<0.001$ and lysed RBC ($p<0.05$). The same effect was observed when samples were incubated with the extract and THBP ($p<0.001$, $p<0.01$, $p<0.001$, respectively).

In RBC, S-nitrosylation significantly ($p<0.05$) increased after extract incubation. RBC deformability was increased by the extract alone ($p<0.01$) compared to control and by the extract with THBP ($p<0.01$) compared to THBP alone. In contact with the adhesion protein laminin at 20 µg/well, adhesion of HUVEC was significantly decreased by the extract alone ($p<0.001$ compared to control) and with THBP ($p<0.001$ compared to THBP) [Grau 2016].

An IC_{50} of 11.2 ± 0.12 µg/mL was obtained in the DPPH assay with an ethanolic extract (DER 7-9.5:1, 80% V/V) containing approx. 137 mg/g of quercetin and 58 mg/g of rutin [Aouey 2016].

Cytotoxic activity
An ethanolic extract (not further specified, 70% V/V) showed IC_{50} values of 1.03 ± 0.2 mg/mL and 80 ± 5 ng/mL, inhibiting proliferation of mouse peripheral blood leucocytes and mice Ehrlich ascites carcinoma cells respectively [Antonyan 2014].

In vivo experiments

Antihyaluronidase activity
A hydroalcoholic dry extract (50-80% V/V) from red vine leaf or a red vine leaf infusion were administered orally to mice for 3 days. Hyaluronidase and Indian ink were injected i.p. 105 minutes after the last administration. Hyaluronidase alone induced diffusion of the Indian ink, while hyaluronidase at 1-2 IU/kg and 3-4 IU/kg b.w. was inhibited by the hydroalcoholic dry extract at 10 mg/kg and 25 mg/kg respectively. Hyaluronidase at 1-3 IU/kg was inhibited by red vine leaf infusion at 250 mg/kg [Abeles 1962].

Action on capillary resistance
In guinea pigs with reduced capillary resistance (measured using an angiopraximeter) due to vitamin C deficiency, i.p. administration of a hydroalcoholic dry extract (50-80% V/lV) for 3 days at 20-50 mg/kg b.w. increased capillary resistance more effectively than similar administration of a red vine leaf infusion at 250-500 mg/kg [Abeles 1962].

Hepatoprotective and nephroprotective activity
Nephrotoxicosis was induced in mice by intragastric administration of 25 µg of the mycotoxin citrinin twice a week for 12 weeks. One group was also given 0.5 mL of an aqueous extract (50 g of fresh leaf in 200 mL of water) for 20 weeks. The control group received the toxin only. Blood analysis and histopathological examination of the kidneys revealed positive effects in the extract-treated group, estimated as up to 41% recovery from renal damage [Bilgrami 1993].

The hepatoprotective effects of an ethanolic extract (80% V/V, DER 6:1) and its $CHCl_3$, EtOAc, *n*-BuOH and water fractions containing 89.4 ± 2.4, 216.0 ± 5.1, 91.2 ± 2.1 and 68.6 ± 1.4 mg/g of total phenolics expressed as GAE equivalents were investigated against CCl_4-induced hepatotoxicity in male Wistar-albino rats. At a dose of 125 mg/kg of the extract, the plasma and liver MDA levels were reduced by 45.7% ($p<0.05$) and 14.0% respectively. GSH content in the liver was increased by doses of 250 and 125 mg/kg as compared to the CCl_4 and control groups. At these doses, severity of histopathological injury was decreased. A dose of 62.5 mg/kg did not produce any hepatoprotective or antioxidant effects.

Among the four fractions, the n-BuOH fraction at 83 mg/kg demonstrated antioxidant activity by decreasing the ALT and significantly the AST ($p<0.001$) activities by 9.9% and 31.8% respectively, and the hepatic MDA level by 29.2% ($p<0.05$), as well as by increasing hepatic GSH levels by 50.8% ($p<0.001$), as compared to the CCl_4 and control groups. Improvements

of histopathological parameters were also observed. The water fraction at 73.64 mg/kg significantly ($p<0.001$) reduced the plasma MDA level by 82.5%, but did not improve histopathological parameters [Orhan 2007].

Healthy male adult Wistar rats were pretreated with 100 mg/kg p.o. of an aqueous dry extract (DER 4-6:1) for 17 days before i.p injection of 1.25 mL/kg of CCl_4. In the liver the extract significantly restored the CCl_4-induced elevated levels of serum alanine aminotransferase ($p<0.001$), ALP, γ-glutamyl transferase and bilirubin ($p<0.01$) as well as the CCl_4-induced reduction in levels of serum albumin ($p<0.001$) and total protein ($p<0.01$). CCl_4-induced changes in TC, triglycerides, VLDL-cholesterol ($p<0.001$), HDL-cholesterol and LDL-cholesterol ($p<0.01$) were also ameliorated. The increased hepatic MDA level was significantly decreased by the extract ($p<0.001$). In the kidney, the extract significantly inhibited the CCl_4-induced raised levels of creatinine, uric acid, calcium and MDA ($p<0.001$). Restoration of the histopathological features in both organs' tissues were also observed [Ahmed 2015].

Anti-inflammatory activity
In a carrageenan-induced rat paw oedema test in Wistar rats, a methanolic extract (not further defined) demonstrated significant ($p<0.01$) inhibition of inflammation at oral doses of 200 and 400 mg/kg, with a reduction of paw volume of 58.6% and 67.3% respectively after 3 h, when compared to control. In the histamine-induced paw oedema test, the extract significantly ($p<0.01$) reduced the paw volume by 46%, 66.7% and 76% at 100, 200 and 400 mg/kg b.w. p.o respectively [Singh 2009].

In the carrageenan-induced hind paw oedema model in Swiss albino mice, maximal anti-inflammatory activity was observed 5h after oral administration of doses of 100 and 200 mg/kg (34.62 and 36.20%) and 4h after administration of 400 mg/kg (50.02%) of an ethanolic extract (80% V/V, DER 7-9.5:1) containing 137.3 ± 10.3 mg/g of quercetin and 58.03 ± 4.2 mg/g of rutin. Oral doses of 100, 200 and 400 mg/kg of this extract also significantly ($p<0.001$) inhibited acetic acid-induced vascular permeability by 37.16%, 59.89% and 68.18% respectively, when compared to control [Aouey 2016].

Antinociceptive activity
In Swiss Albino mice, oral doses of 100, 200 and 400 mg/kg b.w. of the same extract significantly ($p<0.05$) and dose-dependently reduced the number of acetic acid-induced writhings by 48.15%, 57.97% and 68.09% respectively. In the early phase of the formalin test in mice, the extract reduced the licking time in a dose-dependent manner. In the late phase, the doses of 200 and 400 mg/kg significantly ($p<0.001$) inhibited the licking response with licking times of 33.35 ± 2.29 s and 23.79 ± 1.43 s respectively, when compared with the control group (43.69 ± 3.92 s) [Aouey 2016].

In Swiss albino mice, oral doses of 100, 200 and 400 mg/kg b.w. of a methanolic extract, administered 60 min before formalin injection to induce paw licking, demonstrated significant and dose-dependent reductions in pain compared to control, exhibited by inhibition of licking times of 2.89% ($p<0.05$), 30.97% and 50.71% ($p<0.01$) respectively. The extract also demonstrated a significant ($p<0.05$ to $p<0.01$) increase in the latency time for thermal stimulation in the tail flick test after 30, 60 and 120 min [Singh 2009].

Antipyretic activity
Doses of 200 and 400 mg/kg p.o. of an ethanolic extract (80% V/V, DER 7-9.5:1), containing 137.3 ± 10.3 mg/g of quercetin and 58.03 ± 4.2 mg/g of rutin, significantly ($p<0.01$) reduced rectal temperature 23h after yeast-induced pyrexia in Swiss Albino mice when compared to control, demonstrating activity comparable with 100 mg/kg p.o. of paracetamol ($p<0.001$) [Aouey 2016].

Effects on endurance
An extract (not further defined), containing 59% of polyphenols, 0.6% of anthocyanins and 0.02% of resveratrol, was administered to male BALB/c mice for 10 weeks at 0.2 or 0.5% (w/w) of a standard diet. Compared to control (standard diet alone), the extract at 0.2% and 0.5% dose-dependently increased swimming endurance capacity by 11.4% and 34.3% respectively. Mice fed with 0.5% of the extract had significantly ($p<0.05$) longer swimming times than controls at week 10. Plasma lactate was significantly ($p<0.05$) lower at the end of 10 weeks treatment in the 0.5% extract group when compared to control. The concentration of non-esterified fatty acids after treatment was 21% higher than in the control group ($p<0.05$). Significant differences in plasma glucose and triglyceride levels were not observed. A significant ($p<0.05$), dose-dependent increase of fatty acid oxidation enzyme activity was also observed as compared to the control group. mRNA expression levels of several lipid metabolism and mitochondrial function related genes and transcription factors in soleus muscle, as well as hormone-sensitive lipase in mesenteric adipose tissue, were significantly ($p<0.05$) upregulated in the 0.5% extract group compared to control [Minegishi 2011].

Antidiabetic and antioxidant activity
An aqueous dry extract (DER 5:1), and various fractions, were assessed for their effect on blood glucose in normoglycaemic, glucose-hyperglycaemic and streptozotocin-induced (STZ) diabetic rats, as well as for renal, hepatic and cardiac antioxidant activity. The extract was administered at 250 and 500 mg/kg b.w. p.o. as a single dose (acute) or daily for 15 days (subacute). After the single dose, significant hypoglycaemic activity was demonstrated in the glucose-hyperglycaemic rats after 2h at 250 mg/kg ($p<0.001$) and 500 mg/kg ($p<0.05$), and after 4h at 500 mg/kg ($p<0.001$) in the streptozotocin-induced (STZ) diabetic rats, when compared to control, with no significant activity in normoglycaemic rats. In the subacute test, blood glucose levels were significantly ($p<0.001$) and increasingly reduced on days 5, 10 and 15, at both doses, in STZ-diabetic rats as compared to control. The extract at both doses also exhibited greater hypoglycaemic activity than the positive control tolbutamide at days 5, 10 and 15.
Liver, kidney and heart were assessed for MDA and GSH levels on day 15. Liver MDA was significantly ($p<0.05$) reduced at 500 mg/kg, kidney MDA at both doses ($p<0.001$) and heart MDA at 250 mg/kg ($p<0.01$) in STZ-diabetic rats compared to control diabetic rats. GSH levels were most significantly increased ($p<0.001$) in the liver at 500 mg/kg (68.8%), less significantly ($p<0.05$) in the heart and not significantly in kidney. However, GSH levels decreased in the liver, heart and kidney at 250 mg/kg, in the STZ-rats compared to control diabetic rats [Orhan 2006].

Pharmacological studies in humans
No data available.

Clinical studies

Chronic venous insufficiency
After a 2-week placebo run-in period, 260 patients with CVI (Widmer's stages I-II) were randomly assigned to double-blind treatment with 360 mg (n = 87) or 720 mg (n = 85) of an aqueous dry extract (5-7:1), or placebo (n = 88), once daily for 12 weeks, followed by a 2-week follow-up period on placebo. The mean lower leg volume (measured by water displacement plethysmography) increased by 33.7 mL after 12 weeks in the placebo group and decreased significantly ($p = 0.0001$)

by 42.2 and 66.2 mL in the groups treated with the extract at 360 mg/day and 720 mg/day respectively. Reductions in ankle circumference followed a similar pattern but were less marked. Significant (p = 0.0001) improvements in key CVI symptoms (tired and heavy legs, sensation of tension, tingling and pain) were observed in both of the active treatment groups compared to the placebo group [Kiesewetter 2000].

In an open, multicentre observational study, 65 male and female patients suffering from CVI (Widmer's stages I or II) received 360 mg of an aqueous dry extract (4-6:1) daily for 42 days. All four subjective symptoms evaluated (tired and heavy legs, sensation of tension in the legs, tingling sensations in the legs, pain in the legs) improved compared to baseline. Global efficacy of the treatment was rated by both patients and investigators as good or satisfactory in approximately 80% of the patients [Schaefer 2003].

A randomized, double-blind, placebo-controlled, crossover study was carried out to determine the effect of an aqueous dry extract (4-6:1) on cutaneous microvascular blood flow, transcutaneous oxygen pressure ($tcpO_2$) and leg oedema in patients with CVI (Widmer's stages I or II). After a 2-week run-in period the treatment consisted of either 360 mg of extract (n = 36) or placebo (n = 35) once daily for 6 weeks, followed by a 4-week wash-out period with placebo and then another 6-week treatment period. Microvascular blood flow and $tcpO_2$ values increased significantly ($p<0.0001$) after verum treatment. Significant ($p<0.0001$) reductions in calf and ankle circumferences were also observed [Kalus 2004].

In an open observational study, 39 patients with CVI (Widmer's stages I or II) received 2 × 180 mg of an aqueous dry extract (4-7:1) daily for 6 weeks. The calf volume measured by water plethysmography, the circumference of the leg at a fixed height, and the intensity of sensation of heaviness and pain on a visual analogue scale significantly ($p<0.001$) decreased after 2, 4 and 6 weeks of treatment [Monsieur 2006].

In a randomised, double-blind, placebo-controlled study, patients with CVI (CEAP stages 3-4a) received, after a 2-week run-in period on placebo, either 720 mg of an aqueous dry extract (4-6:1) (n=126) or placebo (n=122) for 12 weeks. The extract significantly (p=0.0268) reduced lower limb volume compared to placebo. No significant difference was observed in calf circumference between groups. At day 84, leg pain (assessed by VAS) was significantly (p=0.047) decreased in verum treated patients compared to placebo, whereas no significant difference was observed for other subjective symptoms between the groups [Rabe 2011].

In an open, single blind, placebo-controlled study, 17 healthy women suffering from swollen legs received 600 mg of an ethanolic dry extract (not further specified) daily for 6 weeks, followed by placebo for 6 weeks after a 2-month wash out period. After 6 weeks of verum treatment, swelling of the right leg had decreased significantly ($p<0.018$) compared to placebo. Swelling of the left leg was significantly reduced compared to baseline, both in the morning and in the evening, but this effect was not significant when compared to placebo [Perrinjaquet-Moccetti 2013].

In an open study involving 62 women with orthostasis-dependent phlebopathy of the lower limbs and a history of long term hormone replacement therapy, 360 mg of an aqueous dry extract (DER 4-6:1) was administered daily for 6 months. During the first 3 months, calf circumference decreased significantly (p=0.001) from 36.77 ± 2.89 cm to 35.98 ± 2.83 cm and then remained stable for the following 3 months. Ankle circumference also decreased, but to a lesser extent. The evening diameter of the great saphenous vein significantly (p=0.001) decreased from 0.7 ± 0.11 cm to 0.65 ± 0.99 cm. A decrease in the intensity of symptoms of venous insufficiency was observed with a VAS. The effects were most pronounced in the first 3 months of the study but were maintained for the 3 subsequent months [Tsukanov 2014].

Pharmacokinetic properties

No data are available on pharmacokinetic properties of red vine leaf extracts or corresponding preparations. Some data exist on absorption and metabolism of relevant individual flavonoids [Zuo 2006; Manach 2004; Manach 2005; Williamson 2005].

Preclinical safety data

Acute toxicity

A single dose of 2 g/kg b.w. p.o. of a methanolic extract (not further specified) did not cause any mortality in albino Wistar rats after 14 days. The LD_{50} was greater than 2 g/kg [Singh 2009].

No toxic effects or pathological anatomical changes were observed after oral administration of an aqueous dry extract (4-6:1) to mice and rats at up to 10 g/kg b.w. [Petrini 2003].

Repeated dose and chronic toxicity studies

No adverse effects were observed in rats after oral doses of the same extract at 250 mg/kg b.w. for 90 days [Petrini 2003].

Mutagenicity and carcinogenicity

In the Ames test, no mutagenic effects of an aqueous extract were evident at concentrations ranging from 8 up to 5000 µg per plate on *Salmonella typhimurium* strains TA 98, TA 100, TA 1535, TA 1537 and TA 1538 [Anonymous 1991].

Oral administration of an extract at 1.0, 3.0 and 10.0 mL/kg did not cause any mutagenic effects in the micronucleus test in mice [Anonymous 1992].

Concentrations from 10 up to 400 µg/mL and 1 up to 5 mg/mL of an extract had no mutagenic effect on Chinese hamster V79 cells [Anonymous 1993a].

Reproductive toxicity

No teratogenic effects were observed in animal studies using an aqueous dry extract (4-6:1) [Petrini 2003].

After administration of an extract (containing 1.92% of quercetin 3-glucuronide, 0.8% of isoquercitrin and 2.96% of total flavonoids) by gavage to pregnant rabbits at 300, 1000 and 3000 mg/kg b.w. from the 6th to the 18th day of pregnancy no teratogenic effects were observed [Anonymous 1993b].

Clinical safety data

Daily doses of 360-720 mg of an aqueous dry extract (4-7:1) taken for periods of 6-12 weeks by over 400 patients in clinical studies were generally well tolerated; reported adverse events were usually mild in nature, the most common being gastrointestinal disorders [Kalus 2004; Shaefer 2003; Kiesewetter 2000]. In two placebo-controlled studies more adverse events were reported in placebo groups than in verum groups [Kalus 2004; Kiesewetter 2000]. In at least 1% of patients in treated (n=126) and placebo (n=122) groups, nasopharyngitis, hypercholesterolemia, oropharyngeal pain, urticaria and back pain were also observed [Rabe 2011].

VITIS VINIFERAE FOLIUM	Red Vine Leaf	Online Series, 2020
ZINGIBERIS RHIZOMA	Ginger	Supplement 2009

E/S/C/O/P Monographs

Online Series

The Scientific Foundation for Herbal Medicinal Products

The second edition of ESCOP Monographs, published as a hardback book in 2003 with a Supplement in 2009, has been widely acclaimed for its authoritative information on the therapeutic uses of herbal medicines. Monographs covering a total of 107 herbal substances include extensive summaries of pharmacological, clinical and toxicological data, and copious references to scientific literature form an important part of each text.

Although publication in the form of books was convenient in the past, ESCOP recognizes that online publication now offers a number of advantages, not least in facilitating rapid publication of individual monographs as soon as all stages of preparation have been completed. Commencing from 2011, therefore, new and revised monographs will be published online only.

The European legislative framework for herbal medicines has advanced considerably over the past decade. Directive 2004/24/EC introduced a simplified registration procedure for traditional herbal medicinal products in EU member states and imposed a 2011 deadline for the registration of certain products on the market. The Committee on Herbal Medicinal Products (HMPC), established in 2004 as part of the European Medicines Agency, has made substantial progress in the preparation of Community Herbal Monographs and associated documentation to provide a more harmonized approach to the scientific assessment of herbal medicinal products throughout the European Community

Whether the evaluation of a herbal medicine is based on evidence of clinical efficacy (*well-established use*) or on experience and historical use of that product (*traditional use*) those involved at all levels of the regulatory process need access to detailed, reliable and structured summaries of the available efficacy and safety data. ESCOP monographs meet that requirement and offer an invaluable source of scientific information on herbal medicines to regulators, manufacturers, academics, researchers, health professionals and numerous others.
